**Lecture - 52**  
**First Order Differential Equations**

(Refer Slide Time: 00:22)

So, welcome back and this is lecture number 52. Today will be talking about this First Order Differential Equations, and mainly we will consider first order and the first degree differential equations and their solution techniques.

(Refer Slide Time: 00:30)

Equation of First Order and First Degree

We shall consider two standard forms of differential equation

i)  $\frac{dy}{dx} = F(x, y)$

ii)  $M(x, y) dx + N(x, y) dy = 0$

The slide features a yellow background with a dark blue curved border on the right. At the bottom, there are logos for 'swayam' and other educational institutions, along with a small video feed of a man in a suit.

So, today we will focus on these two standard forms; the one we will consider  $dy$  over  $dx$  is equal to  $F(x, y)$ . So, the function of  $x, y$  right-hand side and the other form we will be discussing in this lecture that will be  $M(x, y) dx + N(x, y) dy = 0$ . So, these are the two types of first order differential equations we will be covering in this and the next few lectures.

(Refer Slide Time: 01:03)

Solution Methods

➤ Separation of Variables

If a differential equation can be written in the form

$$f_1(y) \frac{dy}{dx} = f_2(x) \Rightarrow \int f_1(y) dy = \int f_2(x) dx + C$$

Then we say variables are separable in the given differential equation.

Solution:  $\int f_1(y) dy = \int f_2(x) dx + C$

The slide features a yellow background with a dark blue curved border on the right. At the bottom, there are logos for 'swayam' and other educational institutions, along with a small video feed of a man in a suit.

So, the solution techniques. So, what are the solution methods? The first one is the separation of variables. So, we will quickly review some of the techniques which are

very fundamental of basics and they are required at a every stage for solving the differential equations. So, the one of them is the separation of variable.

So, here if a differential equation can be written in this form. So, we have  $f_1(y)$  and  $dy$  over  $dx$  is equal to  $f_2(x)$ . So, the point here is that everything the function of  $y$  if we can collate to one side and the other side the function of  $x$ , in that case we call that this equation is variable separable because now we can easily integrate this because the left-hand side only the function of  $y$  and the right-hand side everything of function  $x$ .

So, if we can put in such a form then we can easily integrate these equations and then we say that the variable variables are separable in the given differential equation, and the solution for such differential equation once we separate the variables then it can be written as we can simply integrate this here or we can first write down this equation as this  $f_1(y)$  and  $dy$  is equal to this  $f_2(x)$  and  $dx$  and then we can simply integrate this equation with this constant of integration. So, this is equal here. So,  $\int f_1(y) dy$  is equal to  $\int f_2(x) dx$  and plus this constant of integration.

(Refer Slide Time: 02:52)

Example:  $\frac{dy}{dx} = e^{x-2y} + x^2 e^{-2y}$

$e^x \cdot e^{-2y} + x^2 \cdot e^{-2y}$

So, see one example of this kind which is given here that  $dy$  over  $dx$  is equal to  $e$  power  $x$  minus  $2y$  plus  $x$  square and  $e$  power minus  $2y$ . So, if we take a close look here at the right-hand side of this function what we observe that  $e$  power  $x$  because this we can write down this first here as  $e$  power  $x$  in to  $e$  power minus  $2y$  and this term we have already in the separable form, so  $e$  power minus this  $2y$ . And what we do now,  $e$  power minus  $2y$

we can take as a common and that can go to the other side of the equation and this one side it will remain as e power x plus x square. So, this equation is variable separable which we can easily do and then we can integrate it.

(Refer Slide Time: 03:42)

Example:  $\frac{dy}{dx} = e^{x-2y} + x^2 e^{-2y}$

Rewrite:  $e^{2y} \frac{dy}{dx} = e^x + x^2$

Integrating both side:  $\frac{e^{2y}}{2} = e^x + \frac{x^3}{3} + c_1$

or  $e^{2y} = 2e^x + \frac{2}{3}x^3 + c$

So, here we can rewrite this. So, we multiply it basically e power 2y to this equation and automatically the right-hand side becomes now e power x plus x square, so free from y. So, we have this side everything the function of y and the right-hand side we have the function of x.

So, now, we can easily integrate this equation and integrating we will get because e power 2y, when we integrate we will get e power 2y and divided by 2. The right-hand side here we have e power x which you will give e power x the exponential function will remain as it is and here x square will become x cube by 3, when we integrate this x square and one constant of this integration which we call here c 1.

What we can do here we can multiply by 2 for instance just to again rewrite the solution. So, we have here e power 2y is equal to this 2 will go to the right-hand side, so 2 e power x plus this 2 by 3 and this x cube and plus 2 times c 1, which we have denoted again by a constant here c. So, this is the solution which is given in this implicit form. So, this is the implicit solution of the given differential equation by separating this variable. So, it was easy to integrate and find the solution. So, this is one of the very basic techniques which we use for solving differential equations.

(Refer Slide Time: 05:22)

➤ Equation Reducible to Separation of Variables

Consider  $\frac{dy}{dx} = f(ax + by + c)$  or  $\frac{dy}{dx} = f(ax + by)$

Substitute  $ax + by + c = v$  or  $ax + by = v$

$\Rightarrow a + b \frac{dy}{dx} = \frac{dv}{dx}$   $\Rightarrow \frac{dy}{dx} = \frac{1}{b} \left( \frac{dv}{dx} - a \right)$

$\frac{1}{b} \left[ \frac{dv}{dx} - a \right] = f(v)$

The other one there are equations which can be reduced to the separable of variables. So, as such in the given in the given equation may not be separated with respect to these variables, but it can be made by some substitution to separable form and then we can again repeat the process which we have done for the separable equations.

So, for instance if we consider this  $dy$  over  $dx$  is equal to  $f$   $ax$  plus  $by$  plus  $c$ . So, if we have here the function of this  $ax$  plus  $by$  plus  $c$  or the form is just  $ax$  plus  $by$ , so as such this given equation may not be in the separable form, but if we make a substitution here. So, in this case we say it is  $a$  we will substitute this  $ax$  plus  $by$  plus  $c$  and we will give a new variable to this expression or we can substitute  $ax$  plus  $by$  when the equation is given in this form.

So, in either case when we substitute let us say here  $ax$  plus  $by$  is equal to plus  $c$  is equal to just new variable  $v$  or in this case  $ax$  plus  $by$  is equal to  $v$ . What will happen? So, if we differentiate now this to get this relation  $dy$  over  $dx$ . So, what will happen?  $a$  times this  $x$  which will give just  $a$  when we differentiate here  $b$   $dy$  over  $dx$  and this is a constant, so  $0$  is equal to  $dv$  over  $dx$ . And the same expression we will get when we differentiate this  $ax$  plus  $by$  is equal to  $v$ . So, does not matter now, whether we are substituting this one when such a differential equation is given or we are substituting here  $v$  when this equation is given. So, in either case we will get this relation that this new variable  $v$  and the derivative with respect to  $x$  will be a plus  $b$  in  $dy$  over  $dx$  form.

Once we have this we can substitute now back to the equation. So, that we get the new differential equation in  $v$ . So,  $v$  is now the dependent variable like  $y$  was earlier here. And now if you substitute for  $dy$  over  $dx$ . So, from here  $dy$  over  $dx$  what we get? The  $dy$  over  $dx$  will be  $dv$  over  $dx$  and this minus this  $a$  to the right-hand side and then we need to divide also by this  $b$ . So, this  $dy$  over  $dx$  will be substituted here in the equation and then we will get this term now here for  $dy$  over  $dx$ , and then is equal to  $f$  and this we have already substituted as  $v$  whether this equation or this equation we will get from both of them exactly this equation which is given here one over  $b$   $dv$  over  $dx$  minus  $a$  is equal to  $f$  the function of  $v$ .

(Refer Slide Time: 08:40)

> Equation Reducible to Separation of Variables

Consider  $\frac{dy}{dx} = f(ax + by + c)$  or  $\frac{dy}{dx} = f(ax + by)$

Substitute  $ax + by + c = v$  or  $ax + by = v$

$\Rightarrow a + b \frac{dy}{dx} = \frac{dv}{dx}$

$\frac{1}{b} \left[ \frac{dv}{dx} - a \right] = f(v) \Rightarrow \frac{dv}{dx} = bf(v) + a \Rightarrow \int \frac{dv}{bf(v) + a} = \int dx$

So, having this equation now we can just rewrite this. So,  $dv$  over  $dx$  will be equal to, so we multiply by  $b$  first, so that will be  $b f v$  and then this  $a$  will also go to the right-hand side. So, we have  $dv$  over  $dx$  is equal to  $b$  times this function of  $v$  plus this  $a$ . And now this equation is in separable form because this right-hand side is having only  $v$ , there is no  $x$  here anymore, so we can take everything to the left-hand side and then  $dx$  this differential of  $x$  can go to the right-hand side. So, we have this separable form which we can integrate as this integral of this one over  $b v$  plus  $a$  and this with respect to  $v$  and then the right-hand side will be the integral of  $x$ .

So, we have this the solution after getting the solution in terms of v we can again substitute whether this v is equal to ax plus by plus c depending on the situation of the giving differential equation. So, we can write down final solution again in terms of y.

(Refer Slide Time: 09:59)

Example:  $\frac{dy}{dx} = \sec(x+y)$

Let  $x+y=v$        $\frac{dy}{dx} = \frac{dv}{dx} - 1$

Then the differential equation becomes:  $\frac{dv}{dx} = \sec v + 1 = \frac{1 + \cos v}{\cos v} = \frac{2 \cos^2 \frac{v}{2}}{2 \cos^2 \frac{v}{2} - 1}$

$\int \left[ 1 - \frac{1}{2} \sec^2 \left( \frac{v}{2} \right) \right] dv = \int dx$

$\frac{2 \cos^2 \frac{v}{2} - 1}{2 \cos^2 \frac{v}{2}} = \int -\frac{1}{2} \sec^2 \frac{v}{2}$

Now, we take this example of this kind. So, dy over dx is equal to this sec x plus y. So, this equation as such given in this form is not separable because we cannot bring all this x to one side and y to other side. So, we have to use the idea which is described just before. That means, this x plus y we will set as y v and having; so here we can now get this dy over dx. So, this is 1 plus dy over dx is equal to dv over dx and then this dy over dx will be dv over dx minus 1. So, we have this change enough from y to v which we can substitute in the given equation. So, the given equation will be considered now as dv over dx minus 1, dv over dx this minus 1 is equal to the sec of this v.

Now, this equation is in separable form and we can integrate this easily. So, before we do. So, let us just simplify this term. So, this is sec v means 1 over cos v, so we can write 1 plus cos v over cos v. And then we can also simplify little most in terms of this v by 2 we can write down as the 2 times cos v means 2 cos square v by 2 that is for 1 plus cos v and here cos v will be 2 cos square v by 2 minus 1.

We have done this because now the integration will be easier. So, all this terms will go to the left-hand side and the dx this differential will go to the right-hand side and then we will integrate it. So, what I will getting the left-hand side when we, so this will be reverse

the order then we have  $2 \cos^2 v - 1$  and divided by  $2 \cos^2 v$  and that will be, so let us just check here. So, this when go to the left-hand side then this will become  $2 \cos^2 v - 1$  over this  $2 \cos^2 v$ . And that is exactly what we have there. So,  $1$  because  $2 \cos^2 v$  divided by  $2 \cos^2 v$  that will be  $1$  and minus this  $1$  by  $2$  and  $1$  over  $\cos^2 v$  will be  $\sec^2 v$  by  $2$ . So, this is now the integrant here  $1 - \frac{1}{2} \sec^2 v$  and this we will integrate over this  $v$ , in the right-hand side we have integral of this  $dx$ .

(Refer Slide Time: 12:56)

Example:  $\frac{dy}{dx} = \sec(x+y)$

Let  $x+y = v$   $\frac{dy}{dx} = \frac{dv}{dx} - 1$

Then the differential equation becomes:  $\frac{dv}{dx} (\sec v + 1) = \frac{1 + \cos v}{\cos v} = \frac{2 \cos^2 \frac{v}{2}}{2 \cos^2 \frac{v}{2} - 1}$

$\int \left[ 1 - \frac{1}{2} \sec^2 \left( \frac{v}{2} \right) \right] dv = \int dx$  implies  $v - \tan \left( \frac{v}{2} \right) = x + c$

Substitute  $v = x + y$   $y - \tan \left( \frac{x+y}{2} \right) = c + x$

So, now this we can integrate. So, this  $v$ ,  $1$  when we integrate over  $v$  this will give us  $v$  and then here the  $\sec^2 v$  by  $2$ , so this half is already here. So, the  $\sec^2$  this  $v$  which will give us  $\tan$  of this  $v$  by  $2$ . So, we have the integral of the left side  $v$  minus for this  $\sec^2$  we have  $\tan v$  by  $2$  and the right-hand side it just the  $x$  plus this constant of integration.

And now we need to substitute back this  $v$  in terms of the  $x$  plus  $y$ . So, that will be now  $v$  is from here  $x$  plus  $y$ . So, we can write down the  $x$  plus  $y$  here minus this  $\tan v$  is again  $x$  plus  $y$  by  $2$  is equal to  $x$  plus  $c$ , so this  $x$  and the left-hand side also we have this  $x$  plus  $y$ . So, when we substitute for  $v$  this was  $x$  plus  $y$  and the right-hand side was also  $x$ . So, this  $x$  gets cancelled and then we have this as the solution that  $y$  minus this  $\tan x$  plus  $y$  by  $2$  is equal to this constant  $c$ .

So, here the given equation again was not in separable form, but by doing this substitution this here  $x + y$  is equal to  $v$  this one, then the new equation which is written now in  $v$  here  $dv$  over  $dx$  is equal to  $\sec v + 1$  this is in separable form and therefore, we could integrate this easily and finally, we got this again implicit solution. So,  $y - \tan x + y/2$  is equal to arbitrary constant.

(Refer Slide Time: 14:41)

**Homogeneous Equations**

A differential of first order and first degree is said to be homogenous, if it is of the form or can be put in the form:

$$\frac{dy}{dx} = f\left(\frac{y}{x}\right)$$

$$\frac{y}{x} = v \Rightarrow \frac{dy}{dx} = v + x \frac{dv}{dx}$$

*Handwritten note:*  $y = xv$   
 $\frac{dy}{dx} = v + x \frac{dv}{dx}$

So, another type of equations we will consider now these are called the homogeneous equations. So, these homogeneous equations differential equation of first order and first degree is said to be homogeneous, if it is of the form or can be put in the form here of this. So,  $dy$  over  $dx$  is equal to this function of  $y$  over  $x$ . So, if we can bring every the function here right-hand side in the form of  $dy$  over  $x$  as a function of  $y$  over  $x$  then we call this differential equation homogeneous differential equation.

And now we have the solution technique which we can use for solving this such a homogeneous equation. And the trick here is that we take this  $y$  over  $x$  as a new variable, so here we have taken this  $v$  and then we can now get this  $dy$  over  $dx$  from this term, so having this relation we have basically  $y$  is equal to  $xv$ . And then  $dy$  over  $dx$  then we differentiate here, so the product rule will be applicable and we have  $v$  here the derivative of  $x$  and plus this  $x$  and the derivative of  $v$ . So, this is what we will get out of this relation.

So,  $dy$  over  $dx$  is equal to  $v$  plus  $x$   $dv$  over  $dx$ . So, having this relation now we can convert our equation which was given in this form  $dy$  over  $dx$  is equal to function of  $y$  over  $x$ . So, this will become now  $dy$  over  $dx$  will be replaced by  $v$  plus  $x$   $dv$  over  $dx$ .

(Refer Slide Time: 16:26)

**> Homogeneous Equations**

A differential of first order and first degree is said to be homogenous, if it is of the form or can be put in the form:

$$\frac{dy}{dx} = f\left(\frac{y}{x}\right)$$

$$\frac{y}{x} = v \Rightarrow \frac{dy}{dx} = v + x \frac{dv}{dx} \quad v + x \frac{dv}{dx} = f(v) \quad (\text{Separable form})$$

$$\int \frac{dv}{f(v) - v} = \int \frac{dx}{x} + c$$

Here  $v$  plus  $x$   $dv$  over  $dx$  is equal to the function of  $v$  because  $y$  over  $x$  we have assumed as  $v$  here. So, this is new equation which is again in separable form because this  $v$  we can take to the right-hand side, so we have  $f(v) - v$ . So, the right-hand side contains everything with  $v$  and the left-hand side with this  $x$ . So, here this is also a separable equation now in  $v$  and now we can write down the solution, so  $dv$  and the right-hand side when we take this  $v$  there this will be now,  $f(v) - v$  is equal to  $dx$  over  $x$  plus  $c$ . So, that is the separable form which we can integrate and find out the solution. After that we can replace this  $v$  by  $y$  by  $x$  to get the solution in terms of  $y$  and  $x$ .

(Refer Slide Time: 17:20)

**Example:**  $(x^3 + 3xy^2)dx + (y^3 + 3x^2y)dy = 0, \quad x > 0$

$$\frac{dy}{dx} = -\frac{x^3 + 3xy^2}{y^3 + 3x^2y} = -\frac{1 + 3\left(\frac{y}{x}\right)^2}{\left(\frac{y}{x}\right)^3 + 3\left(\frac{y}{x}\right)}$$

Substitute  $\frac{y}{x} = v \Rightarrow \frac{dy}{dx} = v + x \frac{dv}{dx}$

$$v + x \frac{dv}{dx} = -\frac{1 + 3v^2}{v^3 + 3v} \Rightarrow x \left(\frac{dv}{dx}\right) = \frac{-v^4 - 6v^2 - 1}{v^3 + 3v}$$

So, we go through this example which is of this homogeneous differential equation. So, if we rewrite this equation this dy over dx form by dividing this differential here. So, dy over dx will be minus because this term will go to the right-hand side so with minus sign and this x cube plus 3 x y square that is a numerator term here and divided by this y cube plus 3 x square y. So, here now we can realize that we can put this in to this y over x form because all these degree here is 3 here also its adding to 3, 2 plus 1, here 3 and here 3.

So, once we have this equation we can easily rewrite in this form because we can divide by this x cube here and also x cube in the denominator. So, by doing this we have 1 plus 3 y over x cube because we have divided this x cube. So, this x will get cancelled we have this square here. So, this will be indeed square term not the cube term. So, we have here the square y over x square and then here y over x this cube and 3 when we divide x cube here, so y over x. So, now, everything here is in terms of this y over x as a function of y over x. So, this equation is in separable form and we can now substitute this y over x as v which we have explained this before and as a result here this dy over dx will be v plus x dv over dx. So, we can substitute now in our equation here. So, v plus this x dv over dx and then we have with this minus sign and then 1 plus 3 this y over x is v, so v square and divided by this v cube and plus this 3 v.

So, now, this equation we can take this  $v$  to the right-hand side and the equation is separable in terms of this  $v$  and  $x$ . So, while taking this to the right-hand side we will get now this minus  $v^4$  and minus  $6v^2$  minus  $1$  and divided by  $v^2$  plus  $3v$ , when we subtract this  $v$  from this right-hand side. So, now, this equation is in separable form we can take this term to the left-hand side and that the right-hand side will go this  $dx$  over  $x$  and then we can integrate easily.

(Refer Slide Time: 20:10)

$$-\int \frac{4(v^3 + 3v)}{v^4 + 6v^2 + 1} dv = \int \frac{4}{x} dx$$

$$\Rightarrow -\ln(v^4 + 6v^2 + 1) = 4 \ln x + \ln c$$

$\ln x^4 + \ln c$

So, we have done, so  $1$  over  $x$   $dx$  and this goes in another other round here. So,  $v$  cube plus the  $3v$  over this  $v^4$  plus  $v$  square plus  $1$  and we have multiplied both the side with  $4$  because the differentiation of this when we get this  $v^4$  plus  $6v^2$ , so that will be coming  $4$  times  $v^3$  and then  $12$  times  $v$ , so again here  $12$ . So, exactly this is the differential of this sitting there. So, we can easily integrate now and here we have  $4$  over  $x$ , so right-hand side also easy to integrate.

So, now, we can integrate. So, this will imply minus. So, again the logarithmic because this derivative of this is exactly this sitting in the numerator. So, we have the logarithmic of this one  $v^4$  plus  $6v^2$  plus  $1$  and is equal to the  $4$  times and again the logarithmic of  $x$  we have assumed  $x$  to be positive. So, plus this constant of integration which we have taken in that logarithmic form. So, any arbitrary constant here, so, logarithmic of  $c$ . And now we can combine these two. So, this we can write as this  $\ln x^4$  and then here we have this  $\ln c$ . So, this is basically  $\ln c x^4$  and this also we can take to the right-hand side,

so we have everything this  $\log x^4$  plus  $\log c$  and plus this  $\log v^4 + 6v^2 + 1$ . So, we can combine all these terms of all these slopes. And what we will get here?

(Refer Slide Time: 21:59)

The slide shows the following mathematical steps:

$$-\int \frac{4(v^3 + 3v)}{v^4 + 6v^2 + 1} dv = \int \frac{4}{x} dx$$

$$\Rightarrow -\ln(v^4 + 6v^2 + 1) = 4 \ln x + \ln c \quad (x > 0)$$

$$\Rightarrow x^4 c (v^4 + 6v^2 + 1) = 1$$

Handwritten notes on the slide:

$$\ln x^4 + \ln c + \ln (v^4 + 6v^2 + 1) = 0$$

$$\Rightarrow \ln (c x^4 (v^4 + 6v^2 + 1)) = 0$$

$$c x^4 (v^4 + 6v^2 + 1) = 1$$

The slide also features the Swamyam logo and a video feed of the instructor in the bottom right corner.

So, just one step before here what we will get the the  $\ln$  here  $x^4$  plus this  $\ln c$  and also, we will get this  $\ln v^4 + 6v^2 + 1$  is equal to 0. So, here if we combine this everything now, so this will be  $\ln$  and the  $c x^4$  and also this  $v^4 + 6v^2 + 1$  and the right-hand side 0 and then taking the exponential both the sides we will get  $v^4 + 6v^2 + 1$  and is equal to the exponential 0 that is one here. So, we got exactly this one here  $c x^4$  and  $v^4 + 6v^2 + 1$  is equal to 1.

(Refer Slide Time: 22:55)

$$-\int \frac{4(v^3 + 3v)}{v^4 + 6v^2 + 1} dv = \int \frac{4}{x} dx$$
$$\Rightarrow -\ln(v^4 + 6v^2 + 1) = 4 \ln x + \ln c \quad (x > 0)$$
$$\Rightarrow x^4 c(v^4 + 6v^2 + 1) = 1$$
$$\Rightarrow cx^4 \left( \frac{y^4}{x^4} + \frac{6y^2}{x^2} + 1 \right) = 1 \Rightarrow \boxed{c(y^4 + 6y^2x^2 + x^4) = 1}$$

So, now this one, so we need to substitute back this  $v$  which was  $y$  over  $x$ . So, here we have  $cx^4$  and this  $v$  is  $y$  over  $x$ . So, we have here  $y^4$  over  $x^4$ , here also we have  $6y^2$  over  $x^2$  plus  $1$  and is equal to  $1$ . And now this  $x^4$  also we can bring to the inside this bracket. So, what we will get?  $c$  times this  $y^4$  plus this  $6x^2y^2$  plus this  $x^4$  and is equal to  $1$ , and that is the solution again given in implicit form. So, we have  $y$  and  $x$  given in implicit form as the solution of the given differential equation.

(Refer Slide Time: 23:43)

➤ Equation Reducible to Homogeneous Form

$$\frac{dy}{dx} = \frac{ax + by + c}{a'x + b'y + c'} \quad \text{where} \quad \frac{a}{a'} \neq \frac{b}{b'}$$

Handwritten notes:

$$\frac{a}{a'} = \frac{b}{b'} = \lambda$$
$$a = a'\lambda \quad b = b'\lambda$$

Now, the last one for this lecture we have the equations which can be reduced to this homogeneous form. So, again the given equation may not be in the homogeneous form directly, but by doing some substitution we can reduce it to the homogeneous form and this is exactly the equation we are talking about the  $\frac{dy}{dx}$  is equal to  $ax + b + \frac{c}{a'}$  and divided by this  $a'$  here. So, it is just the new name of this constant. It is not the derivative naturally. It is just the another constant  $a'$  here  $b'$  and another constant plus this  $c'$  the another name for the constants.

So, when the equation is given in this form and also together with this condition that this  $\frac{a}{a'} \neq \frac{b}{b'}$  because if this is the case here if they are equal this ratio is equal that  $\frac{b}{b'}$  and is equal to then we can assume let us say the  $\lambda$  and then we have the  $a$  is equal to the  $a' \lambda$  and also the  $b$  is equal to this  $b' \lambda$ . Then what will happen? When we have this relation and when we substitute this one then this will become as a function of, so either we replace this  $a$  or we replace  $a'$ . So, what we will get here in this case when we replace  $a$ . So, this everything will become as function of this  $a' x + b' y$  and then we can solve we do not have to exactly do any further substitution by substituting this to the new variable we can solve this equation. But here the condition is given that this  $\frac{a}{a'} \neq \frac{b}{b'}$ .

So, in that case otherwise this is just the by substituting we can reduce to the separable form and then we can solve as we have done before for the equations reducible to the separable form. But here this condition is given; that means, we have to do little more here.

(Refer Slide Time: 26:02)

► Equation Reducible to Homogeneous Form

$$\frac{dy}{dx} = \frac{ax + by + c}{a'x + b'y + c'} \quad \text{where} \quad \frac{a}{a'} \neq \frac{b}{b'}$$

Take  $x = X + h$   $y = Y + k$

where  $X$  &  $Y$  are new variables and  $h$  &  $k$  are constant to be so chosen that the resulting equation in  $X$  and  $Y$  becomes homogeneous.

$$y = Y + k \Rightarrow \frac{dy}{dx} = \frac{dY}{dX} \quad \frac{dy}{dx} = \frac{dY}{dX} \frac{dx}{dx}$$

So, what we do? We take here the substitution that  $x$  is equal to  $X$  plus  $h$  and we take  $y$  is equal to  $Y$  plus  $k$  as the new variable here big  $X$  and this big  $Y$ . So, now, our independent variables we are changing here the  $x$  is  $X$  plus  $h$  and this  $y$  the dependent variable also as  $Y$  plus  $k$ .

Now, by having this substitutions now, this  $h$  and  $k$  are the constants and we have to choose these constants such that this equation become homogeneous because at present this equation is not homogeneous because of these constant terms here. So, these equation we will choose now this  $h$  and  $k$  so that this equation becomes homogeneous. Now, if we substitute this first here let us see what will happen. So, we have this relation  $y$  is equal to  $Y$  plus  $k$  from there we can get this  $dy$  over  $dx$ , we can easily get this  $dy$  over  $dx$  is equal to  $d$  big  $Y$  over big  $Y$  as a function of  $x$  and then here big  $X$  and then big  $X$  over the function of  $x$ . So, we can do this and  $dx$  over  $x$  from this will be one. So, this relation  $dy$  over  $dx$  is equal to  $dY$  over this big  $X$  remain as we have written here.

(Refer Slide Time: 27:39)

**Equation Reducible to Homogeneous Form**

$$\frac{dy}{dx} = \frac{ax + by + c}{a'x + b'y + c'} \quad \text{where} \quad \frac{a}{a'} \neq \frac{b}{b'}$$

Take  $x = X + h$   $y = Y + k$

where  $X$  &  $Y$  are new variables and  $h$  &  $k$  are constant to be so chosen that the resulting equation in  $X$  and  $Y$  becomes homogeneous.

$$y = Y + k \Rightarrow \frac{dy}{dx} = \frac{dY}{dX} \Rightarrow \frac{dY}{dX} = \frac{aX + bY + ah + bk + c}{a'X + b'Y + a'h + b'k + c'}$$

The slide also features a Swamyam logo and a small video inset of a man in a suit.

So, now by this here  $dy$  over  $dx$  is equal to  $dY$  over  $d$  big  $X$  and we can now substitute in this equation, so this  $dy$  over  $dx$  will be replaced by this  $d$  big  $Y$  over  $d$  big  $X$ . And then again, this  $x$  and  $y$  we have to substitute here also  $x$  and  $y$ . So, the new expression here will be again in terms of  $x$  and  $y$ , but then we have also this here  $a$   $h$  plus  $b$   $k$  plus  $c$  and here  $a$  prime  $h$  plus  $b$  prime  $k$  plus  $c$  prime.

And now the idea is that we will set this here we will set because  $h$  and  $k$  we need to choose. So, we will choose this so that this becomes 0 and this also becomes 0. So, once our  $h$  and  $k$  we have chosen, so that these two expressions vanishes here our equation will become as the homogeneous equation and that is the that is the aim here.

(Refer Slide Time: 28:36)

$$\frac{dY}{dX} = \frac{aX + bY + ah + bk + c}{a'X + b'Y + a'h + b'k + c'}$$

In order to make the above equation homogeneous, choose  $h$  and  $k$  such that

$$ah + bk + c = 0$$
$$a'h + b'k + c' = 0$$

(always possible because  $ab' - a'b \neq 0$ )

Getting  $h$  &  $k$  we have  $X = x - h$  &  $Y = y - k$

$$\Rightarrow \frac{dY}{dX} = \frac{aX + bY}{a'X + b'Y} = \frac{a + b\left(\frac{Y}{X}\right)}{a' + b'\left(\frac{Y}{X}\right)}$$

homogeneous in  $X$  &  $Y$

So, by setting these two terms equal to 0 what will happen now?  $ah + bk + c$  is equal to 0 and also this  $a'h + b'k + c'$  is equal to 0 which is always possible to find such  $h$  and  $k$  because these equations are always solvable if we look at the determinant of this coefficient matrix here  $a$ ,  $b$ ,  $a'$ ,  $b'$  for this  $h$  and  $k$  are unknowns. So, this is the determinant which is non-zero that condition is given already in the equation. That means, that we can always solve this equation, these are solvable equations and will get the unique solution indeed.

So, here we will get now the values of  $h$  and  $k$  such that these terms will vanish and then we have these relations, already which we have substituted. So, our equation will convert now  $dY/dX$  into  $(aX + bY)/(a'X + b'Y)$  and this equation is a homogeneous equation which we can write in the  $Y/X$  form, homogeneous in  $X$  and  $Y$  which we can solve using the technique which we have discussed earlier.

(Refer Slide Time: 29:48)

Example:  $\frac{dy}{dx} = \frac{x+2y-3}{2x+y-3}$

Solution: Take  $x = X + h$  &  $y = Y + k$  so that  $\frac{dy}{dx} = \frac{dY}{dX}$

$$\frac{dY}{dX} = \frac{X + 2Y + (h + 2k - 3)}{2X + Y + (2h + k - 3)}$$

Choose  $h, k$  so that  $h + 2k - 3 = 0$  &  $2h + k - 3 = 0 \Rightarrow h = 1$  &  $k = 1$

$$X = x - 1 \quad Y = y - 1$$
$$\frac{dY}{dX} = \frac{X + 2Y}{2X + Y} \quad \text{Take } Y = vX \Rightarrow \frac{dY}{dX} = v + X \frac{dv}{dX}$$

So, let us do this one example in the last one for today's lecture. So, here we assumed this  $x$  is equal to  $X$  plus  $h$  and  $y$  is equal to  $Y$  plus  $k$  and substitute in the equation as discussed before. So, then we have this  $h$  plus  $2k$  minus  $3$  and  $2h$  plus  $k$  minus  $3$ . So, here this  $k$  is indeed a small  $k$  as given here. So, now, we will set this to  $0$  and also this to  $0$  and solve for  $h$  and  $k$ . So, by doing so, we have this  $h$  plus  $2k$  minus  $3$  is equal to  $0$  and this  $2h$  plus  $k$  minus  $3$  is equal to  $0$ , from here we will get  $h$  is equal to  $1$  and  $k$  is equal to  $1$ . So, this satisfy this equation also  $h$  is equal to  $1$ ,  $k$  is equal to  $1$  satisfies the other equation.

That means, our substitution is this big  $X$  is equal to  $x$  minus  $1$  and big  $Y$  is equal to  $y$  minus  $1$  and now we can substitute in this equation naturally this term is  $0$ , this term is  $0$  and we have the homogeneous equation which we know how to solve this equation. So, we need to again substitute this  $Y$  is equal to  $vX$  as explained before for the homogeneous equation and then that will give us this  $dY$  over  $dX$  in terms of this big  $Y$  and big  $X$ ,  $v$  plus  $X$   $dv$  over  $dX$ .

(Refer Slide Time: 31:12)

$$\frac{dY}{dX} = \frac{X+2Y}{2X+Y} \quad \& \quad Y = vX, \quad \frac{dY}{dX} = v + X \frac{dv}{dX}$$
$$\Rightarrow X \frac{dv}{dX} = \frac{1+2v}{2+v} - v = \frac{1-v^2}{2+v}$$
$$\frac{dX}{X} = \left[ \frac{1}{2} \left( \frac{1}{1+v} \right) + \frac{3}{2} \left( \frac{1}{1-v} \right) \right] dv$$
$$\int \frac{2+v}{(1-v)(1+v)} dv$$

And now we have already this that  $dy$  over  $dx$  is this was the equation the homogeneous equation we have substituted this which leads to this  $dY$  over  $dX$  is equal to  $v$  plus  $X$   $dv$  over  $dX$ .

So, we substitute now back to the equation here and we will get this equation which is separable equation. And now we can bring this big  $X$  to the right-hand side and these  $v$  to this left-hand side; that means, we have  $dX$  over  $X$ . And this  $2$  plus  $v$  over  $1$  minus  $v$  square here, so this term here  $2$  plus  $v$  over  $1$  minus  $v$  square which will come with this  $dv$ ; this with the partial fractions because this  $1$  minus  $v$  square we can write down  $1$  minus  $v$  and  $1$  plus  $v$  and then we can do this partial fractions easily. So, that is the result here of the partial fractions and then we will integrate with respect to  $v$ .

(Refer Slide Time: 32:23)

$$\frac{dY}{dX} = \frac{X+2Y}{2X+Y} \quad \& \quad Y = vX, \quad \frac{dY}{dX} = v + X \frac{dv}{dX} \quad \Rightarrow \quad X \frac{dv}{dX} = \frac{1+2v}{2+v} - v = \frac{1-v^2}{2+v}$$

$$\frac{dX}{X} = \left[ \frac{1}{2} \left( \frac{1}{1+v} \right) + \frac{3}{2} \left( \frac{1}{1-v} \right) \right] dv$$

Integrating  $\ln X + \ln C = \frac{1}{2} [\ln(1+v) - 3 \ln(1-v)]$

$$2 \ln(XC) = \ln \left( \frac{1+v}{(1-v)^3} \right) \quad \Rightarrow \quad X^2 C^2 = \frac{1+v}{(1-v)^3}$$

Substitution  $v = \frac{y-1}{x-1} \quad \Rightarrow \quad C^2(x-y)^3 = x+y-2$

So, here by integrating this we get  $\ln x$  and this constant here  $\ln c$  and is equal to this half again here  $\ln 1 + v$  minus 3 times this half is outside, so this is just minus 3 here because of this minus sign and  $\ln 1 - v$  assuming that these are the constants, otherwise we have to take the these are the positive numbers otherwise we have to take the modulus as well.

So, then we have here 2 times, this 2 will go to their and this  $\ln cx$  is equal to this  $\ln \frac{1+v}{(1-v)^3}$  and from here we will get this  $x^2 c^2$  is equal to  $\frac{1+v}{(1-v)^3}$ . And then we need to substitute this  $v$  as  $\frac{y-1}{x-1}$  because this  $h$  and  $k$  were this was  $k$  and this was  $h$  which was 1 there. So,  $v$  in terms of this  $y$  and  $x$  that was given here as  $\frac{Y}{X}$  and then  $Y$  is  $y-1$  and  $X$  is  $x-1$ . So, finally, this  $v$  we have to substitute here to get the relation of  $x$  and  $y$ . So, by substituting this we get this relation  $c^2(x-y)^3 = x+y-2$  and that is the solution written in  $x$  implicit form of a given differential equation.

**Conclusion**

- Separation of Variables
- Equation Reducible to Separation of Variables
- Homogeneous Equations
- Equation Reducible to Homogeneous Form

The slide features a dark blue background on the left with the word 'Conclusion' in yellow script. The main content is on a light yellow background. A small video inset of a man in a suit is visible in the bottom right corner. Logos for IIT Bombay and Swayam are at the bottom.

Well, so we come to the conclusion now. So, this is what we have learnt today, the separable of variables. So, it was kind of review because many of you are already aware with all these techniques. And we have also discussed about the equation reducible to the separable of variable form again, we have also discussed the homogeneous equation and the equation reducible to the homogeneous form.
