Lecture – 09
Partial Derivatives of Functions of two Variables

Hello, welcome to the lectures on Engineering Mathematics I and today's, this is lecture number 9 and we will be talking about Partial Derivatives of Functions of Several variables.

(Refer Slide Time: 00:26)

Partial Derivatives

The **usual derivative** of a function of several variables with respect to one of the independent variables **keeping all other independent variables as constant** is called the partial derivatives of the function with respect to that variable.

Let $z = f(x, y)$; $(x, y) \in \mathbb{R}^2$, $z \in \mathbb{R}$

$$\left. \frac{\partial f}{\partial x} \right|_{(x_0, y_0)} = f_x(x_0, y_0) = \lim_{\Delta x \rightarrow 0} \frac{f(x_0 + \Delta x, y_0) - f(x_0, y_0)}{\Delta x} = \left. \frac{d}{dx} f(x, y_0) \right|_{x=x_0}$$
$$\left. \frac{\partial f}{\partial y} \right|_{(x_0, y_0)} = f_y(x_0, y_0) = \lim_{\Delta y \rightarrow 0} \frac{f(x_0, y_0 + \Delta y) - f(x_0, y_0)}{\Delta y} = \left. \frac{d}{dy} f(x_0, y) \right|_{y=y_0}$$

So, what is Partial Derivative? It is a usual derivative of a function of several variables with respect to one of the independent variable while keeping all other independent variables as constant. So, as written here it is a usual derivative, when we have to keep other independent variable as variables as constant and taking the derivative of one particular with respect to one particular variable and this is called the partial derivative with respect to that variable.

So, for example, we have a function z is equal to $f(x, y)$ and (x, y) belongs to some domain in \mathbb{R}^2 and z belong to \mathbb{R} the real line. So, this partial derivative of f with respect to x at a point (x_0, y_0) which we also denote by $f_x(x_0, y_0)$. This is defined as we said before it is the usual derivative. So, we are taking here derivative with respect to x . So, the fundamental definition of the derivative that limit Δx goes to 0 and then, we will

make an increment here in x_0 . So, $x_0 + \Delta x$; this is the increment in x because we are taking partial derivative with respect to x .

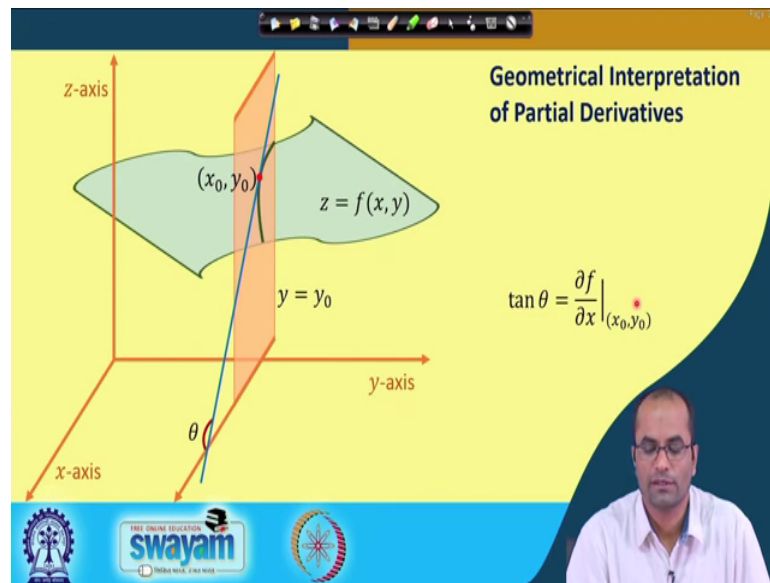

So, here $x_0 + \Delta x$ and then, y_0 we are not changing y_0 . So, it is at the point (x_0, y_0) . So, y_0 will remain as it is and minus the function value at $x_0 + \Delta x, y_0$ and divided by Δx and if this limit exists, then we call that this is a partial derivative with respect to x at this point (x_0, y_0) and it is denoted by f_x at (x_0, y_0) or $\frac{\Delta f}{\Delta x}$ at (x_0, y_0) .

We can also understand this as so here in the function we have kept this y_0 as constant and taking this usual derivatives. So, now, this is here the function of x because we have substituted like y_0 in the function and then, this become a function of one variable x and then, we can take the derivative with respect to x and then later on we can substitute x is equal to x_0 .

So, as written there it is a usual derivative with respect to x . Like here we have use the usual derivative $\frac{d}{dx}$ of this function which is a function of x because we have substituted y is equal to y_0 , the constant value of this y . Similarly, the derivative of f with respect to y at the point (x_0, y_0) and now because we are taking the derivative of with respect to y . So, in that fundamental definition now we will make an increment in y_0 arguments. So, here $y_0 + \Delta y$ and minus the function value of f at $(x_0, y_0 + \Delta y)$ and here divided by Δy .

And again, if this limit exist we call that the partial derivative exists and this is the notation that f_y at (x_0, y_0) or $\frac{\Delta f}{\Delta y}$ at (x_0, y_0) . And again, we can also take like fixing this x_0 , then we have this function as a function of one variable y and then we can take this usual derivative with respect to y at y is equal to y_0 later on. So, this will be the partial derivative with respect to y at the point (x_0, y_0) .

(Refer Slide Time: 04:10)

So, coming to Geometrical Interpretation of the Partial Derivative, we consider this plane three dimensional. So, x axis, y axis and then, we have z axis there and we have some surface where the function z is equal to f x y. So, the surface is represented by this function as z is equal to f x y.

So, if we cut the surface by a plane here y is equal to y 0. Now, this is the plane y is equal to y 0, this is y axis. So, here we have point on the y axis y is equal to y 0 and this is the plane. So, here all the values on of y as y 0 another are constant. So, here we have this plane y is equal to y 0. If we cut this surface, then we as we can see here there is a curve of intersection here by this plane and the surface. So, now, here on this curve if we take a point for example, x naught y naught and we are talking about the partial derivative with respect to x.

Then, if we draw the tangent on this curve at this point x 0 y 0 and then, we note here the angle from the x axis and the tangent of this angle would be precisely the partial derivative of f with respect to x at x naught y naught. So, this is the same definition same geometrical interpretation as we have for the function of one variable. The only difference is that because we have fixed this y. So, y is equal to y naught if we cut this plane over this surface or by this plane, then we will get a curve and then we have we are again back to in one dimensional case and the geometrical interpretation is same that the

tangent of this theta is equal to the partial derivative of f with respect to x at this point x naught y naught.

(Refer Slide Time: 06:13)

Problem - 1: Find the value of $\frac{\partial f}{\partial x}$ and $\frac{\partial f}{\partial y}$ at the point (x, y) of the function $f(x, y) = ye^{-x}$ from the first principal.

$$\frac{\partial f}{\partial x} = \lim_{\Delta x \rightarrow 0} \frac{f(x + \Delta x, y) - f(x, y)}{\Delta x} = \lim_{\Delta x \rightarrow 0} \frac{ye^{-(x+\Delta x)} - ye^{-x}}{\Delta x}$$

$f(x, y) = ye^{-x}$
 $f(x, y) = y \cdot (-e^{-x})$

$$= ye^{-x} \lim_{\Delta x \rightarrow 0} \frac{e^{-\Delta x} - 1}{\Delta x} = -ye^{-x}$$

$$\frac{\partial f}{\partial y} = \lim_{\Delta y \rightarrow 0} \frac{f(x, y + \Delta y) - f(x, y)}{\Delta y} = \lim_{\Delta y \rightarrow 0} \frac{(y + \Delta y)e^{-x} - ye^{-x}}{\Delta y}$$

$f(x, y) = e^{-x}$

$$= \lim_{\Delta y \rightarrow 0} e^{-x} = e^{-x}$$

Coming to the problem find the value of $\frac{\partial f}{\partial x}$ at the point x naught y . It is a general point here of the function $f(x, y)$ is equal to ye^{-x} from the first principle. So, we will use the definition we which we have discussed in the previous slide to compute this $\frac{\partial f}{\partial x}$ and $\frac{\partial f}{\partial y}$ at a general point x, y .

So, what was the definition? $\frac{\partial f}{\partial x}$ at a point x, y . So, we have taken here a general point x, y . So, the definition says that we have to make an increment in x because we are talking about the partial derivative with respect to x . So, $x + \Delta x$ and y minus the function value at x, y ; so, $f(x + \Delta x, y)$ and divided by this increment Δx and then, taking the limit Δx goes to 0. So, then we have to take this function which is $f(x, y)$ is equal to ye^{-x} .

So, in this case this $x + \Delta x, y$. So, it will become y and instead of x we will have $x + \Delta x$. So, $e^{-x - \Delta x}$ and for x , we have $x + \Delta x$ minus the function value at x, y which is ye^{-x} the function itself and divided by Δx . So, now, if we see here $ye^{-x - \Delta x}$ and ye^{-x} is common. So, we can take this outside ye^{-x} . So, what will remain here? $e^{-\Delta x} - 1$ and then, minus 1 because ye^{-x} we have taken common from these 2 terms and then, we have divided by Δx there.

Now, if you compute this limit because as we see Δx goes to 0. This e^0 it is one minus one $0/0$ form. So, we can apply the (Refer Time: 08:11) rule which says that this limit will be like minus e^x here minus Δx , the derivative of this e^x minus Δx and the derivative here will be just 1. So, when Δx goes to 0. So, this limit is going to minus 1. So, the derivative here in this case will become minus 1 and $y e^{-x}$; so, minus $y e^{-x}$.

Now, for the partial derivative with respect to y , so our definition will change now. So, x will remain as it is and they will be incrementing y . So, $y + \Delta y$ and minus $f(x, y)$ divided by Δy . So, now, substituting this in the function; so, we have $y + \Delta y$ and e^{-x} minus the function $y e^{-x}$ and divided by this Δy .

So, again here $y e^{-x}$ is common term $y e^{-x}$ and here also we have $y e^{-x}$. So, what is left then e^{-x} limit Δy goes to 0 and e^{-x} we. So, here we have $y e^{-x}$ which cancel out. So, $y e^{-x}$ and minus $y e^{-x}$ cancel out and then, we have $\Delta y e^{-x}$ over Δy . So, the Δy also cancels out and we get only e^{-x} . So, no need to take common because this is $y e^{-x}$ and here we have minus $y e^{-x}$ is the same term.

So, it basically gets cancelled and then, we have here $y e^{-x}$ term divided by Δy and this Δy and Δy will be cancelled. So, we will get e^{-x} and there is no Δy term here. So, this is just e^{-x} . So, what we can also see? So, this was using the basic definition of or the fundamental definition of partial derivatives. We got the derivatives here with respect to x was minus $y e^{-x}$ and with respect to y it was e^{-x} .

We can also compute this directly because this function is given as $f(x, y)$ is equal to $y e^{-x}$ and the partial derivative with respect to x at the point (x, y) . So, keeping here y constant; treating y constant and taking the usual derivative. So, y will remain as it is and the derivative of e^{-x} will be minus e^{-x} .

So, we have the partial derivative with respect to x which we have already seen here minus $y e^{-x}$. Same we can do to get the partial derivative with respect to y . So, if we take the partial derivative with respect to y here, then this is now x will be treated as constants. So, e^{-x} will be treated as constant and then, when we

take the partial derivative with respect to y . So, this will be 1, then we have e power minus x . So, again we get. So, we can directly compute using the usual definition or visual a known reserves of the derivatives keeping other variable constant ok.

(Refer Slide Time: 11:46)

Relationship: Partial Derivatives & Continuity

A function can have partial derivatives with respect to both x and y at a point without being continuous there. On the other hand a continuous function **may not** have partial derivatives.

Problem - 2: Show that the function

$$f(x,y) = \begin{cases} (x+y) \sin\left(\frac{1}{x+y}\right), & (x+y) \neq 0 \\ 0, & \text{elsewhere} \end{cases}$$

is continuous at $(0,0)$ but its partial derivatives do not exist at $(0,0)$

So, the next. So, what is the Relationship between the Partial Derivatives and the Continuity? We have already discussed in the previous lecture Limits and Continuity. So, if a function can have partial derivative that is a interesting result. So, if a function can have partial derivative without or with respect to both x and y at a point without being continuous there. So, we do not need continuity to for the existence of partial derivative in this case. When we talk about the usual derivatives, the continuity is must for the differentiability, but that is so far we called differentiability or getting the derivative there in case of single functions of single variable, we need continuity of the function.

But in this case a function can have partial derivatives with respect to both x and y at a point without being continuous there. On the other hand, a continuous function may not have partial derivatives. So, other way around, we can have a continuous function, but it may not have partial derivative. So, anything is possible and we will see now in this example which shows that this function we will check now is continuous, but its partial derivatives do not exist. So, that is a one example which shows that the function is continuous, but the partial derivative both the partial derivatives do not exist at $0 0$.

(Refer Slide Time: 13:17)

Continuity at (0, 0)

$$\lim_{(x,y) \rightarrow (0,0)} f(x,y) = 0 = f(0,0), \quad f(x,y) = (x+y) \sin\left(\frac{1}{x+y}\right)$$

Consider

$$|f(x,y) - 0| = \left| (x+y) \sin\left(\frac{1}{x+y}\right) \right| \leq |x+y| \leq |x| + |y| \leq \sqrt{x^2 + y^2} \cdot \sqrt{2} \cdot \sqrt{x^2 + y^2} = \sqrt{2} (x^2 + y^2)$$

Handwritten notes on the slide:

$$\begin{aligned} & (|x| - |y|)^2 \geq 0 \\ \Rightarrow & x^2 + y^2 \geq 2|x||y| \\ \Rightarrow & 2(x^2 + y^2) \geq x^2 + y^2 + 2|x||y| \\ \Rightarrow & 2\sqrt{x^2 + y^2} \geq (|x| + |y|) \\ \Rightarrow & \sqrt{2}\sqrt{x^2 + y^2} \geq |x| + |y| \end{aligned}$$

So, let us check the continuity at 0 0. So, we have this function here $f(x, y)$ is equal to $x + y \sin \frac{1}{x + y}$ and we want to show for the continuity that this limit if we take the limit (x, y) goes to $(0, 0)$ of this function $f(x, y)$, then this limit is 0.

If this limit is 0 because the function value we have seen a 0 here at $(0, 0)$. So, we will show that this limit here is equal to the function value than the function is continuous. We can use for example, the delta epsilon definition or we can also do directly as we have done in the previous lecture. So, let us just go through the standard definition of epsilon delta.

So, here $f(x, y) - 0$, the function value is equal to this difference. So, here that is in the function itself $x + y \sin \frac{1}{x + y}$ and we know that the sin is bounded by 1. So, we can write down this $|x + y| \leq |x| + |y|$. So, this is bounded by 1. So, this will be a big quantity than this one and again, we can we know also this result the triangular inequality that the absolute value of $x + y$ will be less than equal to the absolute value of x plus absolute value of y . And now, we will make a calculation here to substitute this $|x + y|$ or to estimate this absolute value of $x + y$ in terms of the neighborhood.

If you remember we need to set this inequality in terms of the neighborhood so that we can get the relation with delta and epsilon. So, here if we consider this absolute value of $(|x| - |y|)^2$, this will be always positive because this is a

whole square term and then, we have here x square plus y square and this will be minus 2 times absolute value of x minus absolute value of y which I can bring to the right hand side. So, the right hand side will become 2 absolute value of x and absolute value of y.

Now, if I add both the sides this x square plus y square. So, here it will become 2 times the x square plus y square and the right side, it will be x square plus y square and this plus 2 times x and y. This the right hand side, we can write down as absolute value of x, absolute value of y whole square and the left hand side is a 2 times sorry x square plus y square. And now, we can take the square root here. So, this will become as a square root 2 and a square root of x square plus y square and less than equal to this is less than less than equal to absolute value of x plus absolute value of y.

This is other way round. So, this is greater than equal to because here it was greater than. So, this is greater than, this is greater than equal to this absolute value of x plus absolute value of y. So, now, we can replace this term here the absolute value of x plus y by greater the larger quantity here a square root 2 and a square root x square plus y square.

(Refer Slide Time: 17:14)

Continuity at (0, 0)

$$\lim_{(x,y) \rightarrow (0,0)} f(x,y) = 0 = f(0,0), \quad f(x,y) = (x+y) \sin\left(\frac{1}{x+y}\right)$$

Consider

$$|f(x,y) - 0| = \left| (x+y) \sin\left(\frac{1}{x+y}\right) \right| \leq |x+y| \leq |x| + |y| \leq \sqrt{2} \sqrt{x^2 + y^2} < \sqrt{2} \delta < \epsilon$$

Choose $\delta < \frac{\epsilon}{\sqrt{2}}$, then $|f(x,y) - f(0,0)| < \epsilon$ whenever $0 < \sqrt{x^2 + y^2} < \delta$

This implies the function $f(x,y)$ is continuous.

So, let us do that. A square root 2 and a square root x square plus y square and now here exactly we have the neighborhood of this 0 0 point which we can bound by delta. So, here this term can be we can use that inequality for the neighborhood and then, we have a square root 2 into delta and now this difference the aim is to make this difference of f x

y minus 0 less than epsilon. So, this is less than epsilon now, if you make then we will get the relation between delta and epsilon.

So, here choosing this delta from here epsilon by a square root 2 because epsilon is given and then we can find this delta by this relation anything is smaller than this epsilon divided by square root 2 and then, we have that this difference is less than epsilon whenever we choose x, y from this neighborhood; from this neighborhood delta neighborhood of $(0, 0)$ point.

So, this is the epsilon delta approach to prove that the given number is the limit of a function which is here $x + y \sin \frac{1}{x+y}$. So, what we have seen that this 0 is the limit of this $f(x, y)$ function. So, in that case we have proved the continuity. So, this implies that $f(x, y)$ is continuous.

(Refer Slide Time: 18:46)

Partial Derivatives at $(0, 0)$

$$f(x, y) = (x + y) \sin\left(\frac{1}{x + y}\right)$$

$$\lim_{\Delta x \rightarrow 0} \frac{f(x_0 + \Delta x, y_0) - f(x_0, y_0)}{\Delta x} = \lim_{\Delta x \rightarrow 0} \frac{f(\Delta x, 0) - f(0, 0)}{\Delta x}$$

$$= \lim_{\Delta x \rightarrow 0} \frac{1}{\Delta x} \Delta x \sin\left(\frac{1}{\Delta x}\right) = \lim_{\Delta x \rightarrow 0} \sin\left(\frac{1}{\Delta x}\right)$$

\Rightarrow The partial derivative w.r.t. x does not exist.

Similarly, the partial derivative w.r.t. y does not exist.

Next moving to the partial derivatives at $(0, 0)$ points, so we have this function and we can use now this definition delta x goes to 0 and x_0 plus delta x and minus $f(x_0, y_0)$ over delta x . So, since $x_0 = 0$ and $y_0 = 0$, so we are talking about the derivative at $(0, 0)$ point. So, we are taking this limit if this limit exist, then we call the partial derivatives with respect to x exist. If it does not exist, we will call the partial derivatives or partial derivative with respect to x does not exist. So, here in this case we have as per the definition now and delta x goes to 0.

So, this $f \Delta x \rightarrow 0$. So, here y is 0 and then, x will be replaced by Δx . So, we have Δx and $\sin \frac{1}{\Delta x}$ and this $\frac{1}{\Delta x}$ term is here. So, Δx and Δx gets cancelled and then, we get simply this limit $\Delta x \rightarrow 0 \sin \frac{1}{\Delta x}$ and Δx approaches to 0. So, in this case here we do not know what is this limit because the \sin is not definite when this Δx goes to 0. We cannot conclude the value of this one.

So, basically in this case this limit does not exist because we do not know what number is this. So, the limit; that means, the partial derivative with respect to x does not exist in this case and obviously, the similar calculation we can do for y or the partial derivative with respect to y to get this limit and we will find that that the partial derivative with respect to y also does not exist.

(Refer Slide Time: 20:30)

Problem - 3: Show that the function

$$f(x, y) = \begin{cases} \frac{xy}{x^2 + 2y^2}, & (x, y) \neq (0, 0) \\ 0, & \text{elsewhere} \end{cases}$$

is not continuous at $(0, 0)$ but its partial derivatives exist at $(0, 0)$

Choosing the path $y = mx$

$$\lim_{(x,y) \rightarrow (0,0)} \frac{xy}{x^2 + 2y^2} =$$

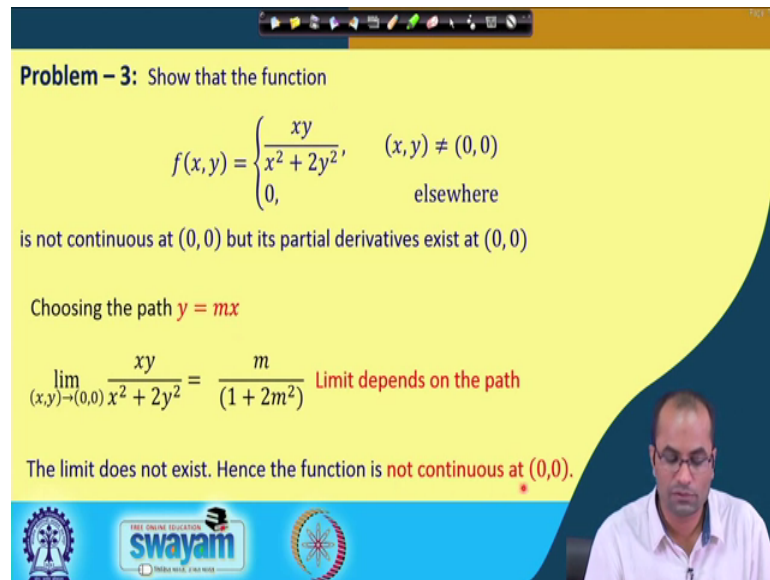

Handwritten note: $\lim_{x \rightarrow 0} \frac{x \cdot mx}{x^2 + 2m^2x^2}$

swayam
Free Online Education

Moving to another problem, we have a now we will show that this function is not continuous, but its partial derivatives exists at 0 0. In the earlier problem, we have seen the function was continuous, but the partial derivatives do not exist. In this case, we will show that the function is not continuous, but its partial derivatives exist; both the partial derivatives exist. So, why this is not continuous? If we choose the path y is equal to mx ; then, what we find because y is equal to mx and then here also y is equal to mx .

So, here x^2 here x^2 here x^2 will come and what we will get. So, here we have x and then y is mx . So, we have x^2 and $2m^2x^2$ and then, the limit x goes to 0 .

(Refer Slide Time: 21:39)

Problem - 3: Show that the function

$$f(x,y) = \begin{cases} \frac{xy}{x^2 + 2y^2}, & (x,y) \neq (0,0) \\ 0, & \text{elsewhere} \end{cases}$$

is not continuous at $(0,0)$ but its partial derivatives exist at $(0,0)$

Choosing the path $y = mx$

$$\lim_{(x,y) \rightarrow (0,0)} \frac{xy}{x^2 + 2y^2} = \frac{m}{1 + 2m^2} \quad \text{Limit depends on the path}$$

The limit does not exist. Hence the function is not continuous at $(0,0)$.

So, here x^2 here x^2 here x^2 . So, we will get this limit as m over $1 + 2m^2$. m over $1 + 2m^2$ and hence, this limit does not exist because it depends on m . For different values of m , we are getting different value of this limit.

Hence, this limit does not exist and the function is not continuous. Now, we will show that though the function is not continuous, but we can compute the partial derivatives with respect to x and with respect to y .

(Refer Slide Time: 22:03)

Partial Derivatives at (0, 0)

$$f(x, y) = \begin{cases} \frac{xy}{x^2 + 2y^2}, & (x, y) \neq (0, 0) \\ 0, & \text{elsewhere} \end{cases}$$
$$\lim_{\Delta x \rightarrow 0} \frac{f(x_0 + \Delta x, y_0) - f(x_0, y_0)}{\Delta x} = \lim_{\Delta x \rightarrow 0} \frac{f(\Delta x, 0) - f(0, 0)}{\Delta x} = \lim_{\Delta x \rightarrow 0} \frac{0 - 0}{\Delta x} = 0$$
$$\lim_{\Delta y \rightarrow 0} \frac{f(x_0, y_0 + \Delta y) - f(x_0, y_0)}{\Delta y} = \lim_{\Delta y \rightarrow 0} \frac{f(0, \Delta y) - f(0, 0)}{\Delta y} = \lim_{\Delta y \rightarrow 0} \frac{0 - 0}{\Delta y} = 0$$

\Rightarrow The partial derivatives w.r.t. x & y exist at $(0, 0)$.

So, the partial derivatives again with the definition we have this fundamental definition which at the 0 0 points become delta x 0 and f 0 0 over delta x. Now, f delta x 0. So, one argument is 0, the y is 0. So, this will become 0 because of this product. So, here it is 0 and then, f 0 0 this is also 0. So, 0 minus 0 over delta x and this is 0 whatever delta x's so, we have here the value of this limit is 0; that means, the partial derivative with respect to x is 0.

Now, the partial derivative with respect to y. So, we have y naught plus delta y in this case and x naught y over delta y. As per the definition, we have because this x naught y naught; you will put 0, we are talking about the partial derivatives at 0 0 point. So, f 0 delta y minus f 0 0 over delta y, again the same argument because here the x is 0 and the product in the numerator is there x y term. So, here this will also become 0. So, this will become 0 and this is 0.

So, 0 minus 0 over delta y and this is 0 and we got again this limit as 0. So, both the partial derivatives with respect to x and with respect to y exist the value of the partial derivatives in both the cases are 0 and the function was are not continuous in this case.

(Refer Slide Time: 23:46)

Problem - 4: Let $f(x,y) = \begin{cases} \frac{2x^3 + 3y^3}{x^2 + y^2}, & (x,y) \neq (0,0) \\ 0, & \text{elsewhere} \end{cases}$

Compute $f_x(0,0)$ & $f_y(0,0)$.

$$f_x(0,0) = \lim_{\Delta x \rightarrow 0} \frac{f(\Delta x, 0) - f(0,0)}{\Delta x} =$$

$\lim_{\Delta x \rightarrow 0} \frac{2 \Delta x}{\Delta x} = 2$

At the bottom of the slide, there are logos for 'swayam' and 'THE ONLINE EDUCATION'.

Another problem, so here we have $f(x,y)$ is equal to $2x^3 + 3y^3$ divided by $x^2 + y^2$. So, we want to compute f_x and f_y at $(0,0)$ point.

So, again as per the definition, we have $f_x(0,0)$ is equal to $f(\Delta x, 0) - f(0,0)$ divided by Δx and Δx goes to 0. This is the partial derivative with respect to x . So, we will substitute now $f(\Delta x, 0)$. So, y will be set here 0; there also 0 and we will get this 2 times. So, this when y will be 0. So, this function will become 2 times x ; simply 2 times x . So, we will get this one 2 times Δx and divided by again Δx here and then, limit Δx goes to 0. So, Δx gets cancel and we will get this value as 0.

(Refer Slide Time: 25:00)

Problem - 4: Let $f(x,y) = \begin{cases} \frac{2x^3 + 3y^3}{x^2 + y^2}, & (x,y) \neq (0,0) \\ 0, & \text{elsewhere} \end{cases}$

Compute $f_x(0,0)$ & $f_y(0,0)$.

$$f_x(0,0) = \lim_{\Delta x \rightarrow 0} \frac{f(\Delta x, 0) - f(0,0)}{\Delta x} = 2$$

$$f_y(0,0) = \lim_{\Delta y \rightarrow 0} \frac{f(0, \Delta y) - f(0,0)}{\Delta y} = 3$$

The function $f(x,y)$ is continuous and also partial derivatives exist.

Handwritten note: 2x³ and 3y³ cancel out on r → 0, f_x = 2, f_y = 3

So, we will get here the value 2 ok. Now, the second when we compute f_y at 0 0. So, we have a similar situation again; the 0 delta y. So, this time the delta y will remain. So, we will have here 3 times and the delta y minus. This $f(0,0)$ is 0 and over delta y and delta y goes to 0. So, here this gets cancelled and you will get this value as 3. So, this is 3 here. So, we have the partial derivative with respect to x as to partial derivative of f with respect to y here as 3. The function is continuous and also partial derivatives exist.

Because in this case we can easily prove that the partial derivatives exist and we have already done this in previous lectures. So, here for example, to see the continuity, we can put x is equal to r cos theta and y is equal to r sin theta and then, this will become simply here the r square will come and then, 2 r cube and cos cube theta plus 3 r cube and sin cube theta and limit r goes to 0.

So, in this case the 1 r will survive in the numerator and the rest term here is bounded. So, this will go to 0. So, the function is continuous and the partial derivatives exist. So, anything is possible. We have seen the example when the function was not continuous partial derivatives exist or the function was continuous, partial derivative do not exist. In this case function is also continuous and partial derivatives also exist.

(Refer Slide Time: 27:01)

Problem - 5: Let $f(x, y) = \begin{cases} \frac{xy}{\sqrt{x^2 + y^2}}, & (x, y) \neq (0, 0) \\ 0, & \text{elsewhere} \end{cases}$

Compute $\frac{\partial f}{\partial x}(x, y)$ & $\frac{\partial f}{\partial y}(x, y)$ and discuss the continuity of these partial derivatives

$f_x(x, y) = \begin{cases} \frac{y^3}{(x^2 + y^2)^{3/2}}, & (x, y) \neq (0, 0) \\ 0, & \text{elsewhere} \end{cases}$

Handwritten derivation for f_x :

$$f_x = \frac{y \cdot \sqrt{x^2 + y^2} - (xy) \cdot \frac{1}{2} \cdot \frac{2x}{\sqrt{x^2 + y^2}}}{(\sqrt{x^2 + y^2})^2}$$

$$= \frac{y(x^2 + y^2) - xy^2}{(x^2 + y^2)^{3/2}}$$

So, this example again to compute the partial derivatives with respect to x and with respect to y and also you will discuss the continuity of these partial derivatives. So, here the f_x when x, y is not equal to 0, 0. So, when x, y is not equal to 0, 0, we have this nice function. The problem is at 0 where we have to defined separately as 0. So, when x, y is not equal to 0, 0, we have this function and we can take the partial derivative f_x here treating this y as constant.

So, just doing this calculation for a partial derivative with respect to x, we can just follow the usual calculations. So, here $x^2 + y^2$ and the square root; so this will be its whole square and then, in the numerator when we take the derivative treating this y as constant.

So, here we will get the partial derivative with respect to x of xy will become y and then, minus this xy as it is and the partial derivative here which will be $\frac{1}{2}$ and then, here this is square root $\sqrt{x^2 + y^2}$ and we are taking partial derivative with respect to x. So, this $2x$ will come and this 2 will get cancel and then, we can multiply here this y term in $x^2 + y^2$ and then we have minus. So, here again this term will go there because this quotient rule.

So, $x^2 + y^2$. So, this will become $y(x^2 + y^2) - xy^2$ and then, divided by this $(x^2 + y^2)^{3/2}$ term and this will also come. So, this will become $\frac{y(x^2 + y^2) - xy^2}{(x^2 + y^2)^{3/2}}$.

So, this here $x^2 y$ will get canceled, we will get y^3 . Exactly this term here y^3 over $x^2 + y^2$ and similarly, we can compute this f_y with respect to y .

(Refer Slide Time: 29:16)

Problem - 5: Let $f(x,y) = \begin{cases} \frac{xy}{\sqrt{x^2 + y^2}}, & (x,y) \neq (0,0) \\ 0, & \text{elsewhere} \end{cases}$

Compute $\frac{\partial f}{\partial x}(x,y)$ & $\frac{\partial f}{\partial y}(x,y)$ and discuss the continuity of these partial derivatives

$f_x(x,y) = \begin{cases} \frac{y^3}{(x^2 + y^2)^{3/2}}, & (x,y) \neq (0,0) \\ 0, & \text{elsewhere} \end{cases}$

$f_y(x,y) = \begin{cases} \frac{x^3}{(x^2 + y^2)^{3/2}}, & (x,y) \neq (0,0) \\ 0, & \text{elsewhere} \end{cases}$

Handwritten note: $f_x(0,0) = \lim_{\Delta x \rightarrow 0} \frac{f(x,0) - f(0,0)}{\Delta x} = 0$

So, we will get just instead of the y will be replaced by x because of the symmetry of the functions. So, we got these 2 and here this partial derivative with respect to x , we have to also compute this with the definition the fundamental definitions.

So, we have to use here what is the f_x at $0,0$. So, at non zero point that non zero point, we can directly compute from here and at $0,0$ we have to use the fundamental definitions. So, the Δx goes to 0 and we have $f(\Delta x, 0) - f(0,0)$ divide by Δx . So, $f(0,0)$ is 0 and here if one of the argument is 0 .

So, this function will become 0 and so, we have 0 minus 0 over Δx . So, this will become 0 . Therefore, we have used here 0 , but we have to use this fundamental definition to get the partial derivative at 0 . So, here also we get 0 and now moving next. So, we want to discuss the continuity. So, to discuss the continuity, we have to see what is the limit of this? Whether the limit of this function is 0 or same thing here that the limit of this is 0 ; then, the function is continuous, otherwise it is not continuous.

Continuity of partial derivatives

$$f_x(x, y) = \begin{cases} \frac{y^3}{(x^2 + y^2)^{3/2}}, & (x, y) \neq (0, 0) \\ 0, & \text{elsewhere} \end{cases} \quad f_y(x, y) = \begin{cases} \frac{x^3}{(x^2 + y^2)^{3/2}}, & (x, y) \neq (0, 0) \\ 0, & \text{elsewhere} \end{cases}$$
$$\lim_{(x,y) \rightarrow (0,0)} \frac{y^3}{(x^2 + y^2)^{3/2}} = \lim_{r \rightarrow 0} \sin^3 \theta = \sin^3 \theta \quad \text{Limit does not exist}$$

The same observation for f_y

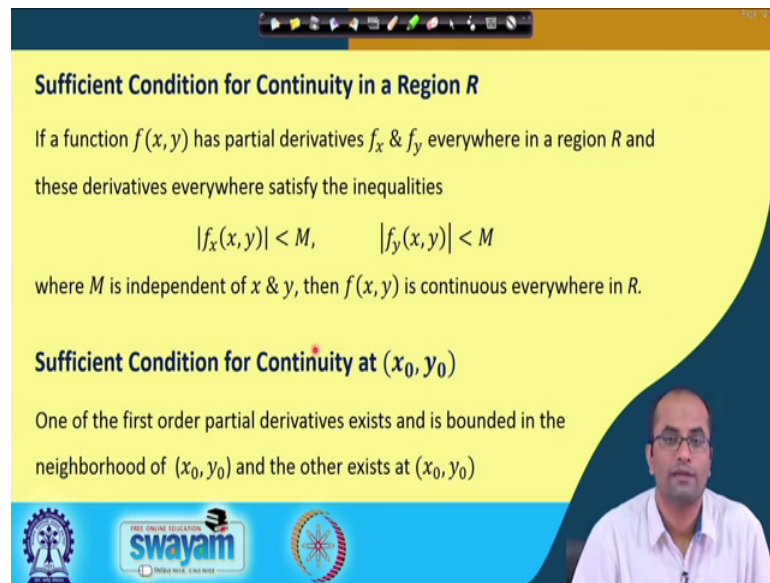

Hence, both f_x & f_y are not continuous

swayam

So, we have to check those limits here. In this case, when we substitute x is equal to $r \cos \theta$ y is equal to $r \sin \theta$. So, we will get here r^3 and here also $r^3 \sin^3 \theta$. So, r^3 will get cancelled and we will get $\sin^3 \theta$. So, this limit depends on θ . So, therefore, this is not continuous. So, this f_x is not continuous because this limit does not exist the limit depend on θ .

For continuity, the limit should exist and it should be equal to the value at $(0, 0)$. So, in this case the limit does not exist. Therefore, these partial derivatives are not continuous; (Refer Time: 31:18) did we can do the similar calculation for f_y . So, both a partial derivatives f_x and f_y , they are not continuous.

(Refer Slide Time: 31:26)

Sufficient Condition for Continuity in a Region R

If a function $f(x, y)$ has partial derivatives f_x & f_y everywhere in a region R and these derivatives everywhere satisfy the inequalities

$$|f_x(x, y)| < M, \quad |f_y(x, y)| < M$$

where M is independent of x & y , then $f(x, y)$ is continuous everywhere in R .

Sufficient Condition for Continuity at (x_0, y_0)

One of the first order partial derivatives exists and is bounded in the neighborhood of (x_0, y_0) and the other exists at (x_0, y_0)

The footer contains logos for Swamyam and other educational institutions.

We have one result on the sufficient which is the sufficient condition for continuity in a region r .

So, what it says if I pass if a function $f(x, y)$ has partial derivatives f_x and f_y everywhere in a region r . So, the existence of the partial derivative here and moreover, these partial derivatives are bounded by some number M here. So, $f_x(x, y)$ in that region is bounded and f_y is also bounded, where this M is independent of x and y . So, then the $f(x, y)$ is continuous everywhere. So, that is the one sufficient condition for the continuity again.

So, if the partial derivatives exist and they are bounded, then the function will be continuous and we can also have a sufficient condition to discuss this continuity at x_0, y_0 . So, here if one of the partial derivatives exist and is bounded in the neighborhood; so, here we have to talk about the neighborhood. So, if one of the partial derivatives exist and is bounded in this neighborhood and the other one exist at this (x_0, y_0) point. Then, also we can say that the function is continuous at (x_0, y_0) point ok.

(Refer Slide Time: 32:46)

Conclusion:

$$\frac{\partial f}{\partial x} \Big|_{(x_0, y_0)} = \lim_{\Delta x \rightarrow 0} \frac{f(x_0 + \Delta x, y_0) - f(x_0, y_0)}{\Delta x} = \frac{d}{dx} f(x, y) \Big|_{x=x_0}$$
$$\frac{\partial f}{\partial y} \Big|_{(x_0, y_0)} = \lim_{\Delta y \rightarrow 0} \frac{f(x_0, y_0 + \Delta y) - f(x_0, y_0)}{\Delta y} = \frac{d}{dy} f(x_0, y) \Big|_{y=y_0}$$

Conclusion

swayam

So, what we have learnt today which will be used in following lectures is the Partial Derivatives; so, it with respect to x this definition we are going to use in many other lectures. So, here the increment with respect to x and then, this quotient we have to take the limit if this limit exists, we will call it partial derivative with respect to x and same thing for the partial derivative of with respect to y.
