Lecture – 20
Change of variables in a Double Integral

Hello students. So, in the last class we looked into the examples of double integrals on rectangular as well as unbounded regions. Today we will start with a change of order of integration and Jacobean transformation. So, how you can how to say transform a double integral into a double integral using Jacobean transformations and all.

So, we will start with a basic a basic theory, the proof of which we will avoid, but I will just give you an idea that how you do the change of variables in a double integral or how you change the order of integration. So, let us start change of variables in a double integral.

(Refer Slide Time: 01:04)

So, the reason why we do the change of variable is that, many double integrals can be evaluated easily if we do the change of variables.

So, sometimes you may have a very complicated double integral given to you and it might seem that it is very difficult to do that, but if you do some certain change of variables, then the overall integral might reduce to a very simple expression and that will

be easy to evaluate and of course, after doing the change of variables, your answer will still remain the same. So, it would not happen that the value of that double integral would change. So, it would still remain the same; however, doing that change of variable actually saved us from a lot of trouble actually.

So, let us see. Suppose we have a bounded function. So, let $f(x, y)$ be a continuous function on a domain or region on a domain E , and let the integral let the variables x and y let the variables x, y in the double integral in the double integral $\int \int f(x, y) dx dy$ be changed to u and v by following relation by following relation. So, what is that relation? So, we are using $x = \phi(u, v)$ and $y = \psi(u, v)$. So, these are some kind of transformation, where ϕ and ψ are continuous functions on e , with continuous first order partial derivative all right; partial derivatives in a certain region E_1 of u, v plane.

So, since we are transforming the variable x and y to the variable u and v so; obviously, from the region e we will get transferred to a region E_1 because for the variable u and v after doing the transformation they might belong to a different region. So, they might bound a different region; however, the dimension will not change. So, x and y they signify the two dimensional geometry. So, then in that case once you are using the transformation, we will get away the transformation function as $\phi(u, v)$, and they will get again transferred to a two dimensional domain. Of course, the region might be two dimensional geometry, but of course, the region might be different and that is why we are saying that these you have ϕ and ψ , they are how to say they are continuous and they have continuous partial derivative in a certain region E_1 so, because they are now in u, v plane.

(Refer Slide Time: 06:04)

The image shows a handwritten derivation on a whiteboard. At the top, the change of variables formula is written:
$$\iint_E f(x,y) dx dy = \iint_{E_1} f(\phi(u,v), \psi(u,v)) |J| du dv.$$
 Below this, a note states: "J is called the Jacobian of the transformation which is given by". Then, the Jacobian matrix is defined as:
$$J = \frac{\partial(x,y)}{\partial(u,v)} = \begin{pmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} \end{pmatrix}$$
 Finally, the determinant of the Jacobian is given as:
$$\Rightarrow |J| = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} \end{vmatrix}$$

So, then the integral $\iint_E f(x,y) dx dy$ can be changed let us write in a new page integral over the region E_1 $\iint_{E_1} f(x,y) dx dy$. So, we are changing x to $\phi(u,v)$. So, let us write $\phi(u,v)$ and we are changing y by $\psi(u,v)$. So, $\phi(u,v)$ and $\psi(u,v)$ and $dx dy$ will be changed to $du dv$; however, we will have an external factor here which is this $|J|$ and this is not actually $|J|$ this has a meaning. So, this has a meaning which is so, J is called the Jacobian of the transformation and when I say transformation, I basically mean this here.

So, this is my transformation and J is the Jacobian of that transformation which is given by given by J equals to $\frac{\partial x}{\partial u} \frac{\partial y}{\partial v} - \frac{\partial x}{\partial v} \frac{\partial y}{\partial u}$ and its basically a matrix $\frac{\partial x}{\partial u} \frac{\partial x}{\partial v} \frac{\partial y}{\partial u} \frac{\partial y}{\partial v}$ and the Jacobian determinant, the Jacobian determinant is basically determinant of this matrix here. So, that is $\frac{\partial x}{\partial u} \frac{\partial x}{\partial v} \frac{\partial y}{\partial u} \frac{\partial y}{\partial v}$.

So, this is basically our Jacobian matrix. So, first of all when we are doing the how to say change of variable, we have to find out these transformation. So, we are the one who has to calculate these two transformation and once we get these two transformation, then we have to calculate the Jacobian determinant so, that we can do the change of variable. But before that we cannot simply put any transformation here. So, that transformation should also have these two properties. So, it should be continuous a continuous function on E_1 and it should have continuous first order partial derivatives as well.

So, once we have all these ingredients and we can do the change of variable in our integral. Now we might or one might ask that change of how do we change.

(Refer Slide Time: 09:05)

Ex: Change the variable $\iint_E f(x, y) dx dy$ to the polar Co-ordinate from Cartesian Co-ordinate, where E is given by $x^2 + y^2 \leq r^2$.

Soln: $x = r \cos \theta$ and $y = r \sin \theta = \psi(r, \theta)$

$$|J| = \begin{vmatrix} \frac{\partial x}{\partial r} & \frac{\partial x}{\partial \theta} \\ \frac{\partial y}{\partial r} & \frac{\partial y}{\partial \theta} \end{vmatrix} = \begin{vmatrix} \cos \theta & -r \sin \theta \\ \sin \theta & r \cos \theta \end{vmatrix} = r(\cos^2 \theta + \sin^2 \theta) = r$$

$$\iint_E f(x, y) dx dy = \iint_{E_1} f(r \cos \theta, r \sin \theta) r dr d\theta$$

So, an example interesting example could be; change the variable let us say any we have an integral over the region E of x, y , change the variable $f(x, y) dx dy$ to the polar coordinate from Cartesian coordinate; where E is given by $x^2 + y^2 \leq r^2$; r can be any a, b, c whatever radius we prefer.

So; obviously, for a circle we substitute x equals to $r \cos \theta$ and we substitute y equals to $r \sin \theta$. So, from here we will have. So, we can calculate the Jacobian. So, let us calculate the Jacobian determinant. The Jacobian determinant is determinant of $\frac{\partial(x, y)}{\partial(r, \theta)}$. So, our new variables are r and θ . So, I can write this as a function of r and θ . So, $\phi(r, \theta)$ and this one is basically $\psi(r, \theta)$, and what is our $\phi(r, \theta)$? It's $r \cos \theta$ and what is our $\psi(r, \theta)$? It is $r \sin \theta$.

So, we have $\frac{\partial x}{\partial r}$; $\frac{\partial x}{\partial \theta}$ and then here we have $\frac{\partial y}{\partial r}$ and then $\frac{\partial y}{\partial \theta}$. So, what is my $\frac{\partial x}{\partial r}$? $\frac{\partial x}{\partial r}$ would be $\cos \theta$ simply $\frac{\partial x}{\partial \theta}$ will be $-r \sin \theta$ and then $\frac{\partial y}{\partial r}$ will be $\sin \theta$ only and $\frac{\partial y}{\partial \theta}$ will be $r \cos \theta$. So, if we evaluate this determinant, then this will be r times $\cos^2 \theta + \sin^2 \theta$.

So, ultimately we will obtain r . Therefore, our integral I which is now transferred into a polar coordinate, our new region E then f of x is $\phi r \theta$. So, that means $r \cos \theta$ and y is $r \sin \theta$ which is $r \sin \theta$, and then we have mod then we have Jacobean determinant which is basically r and then we will have $dr d\theta$. This E can be replaced by 0 to r and from θ can be replaced by 0 to 2π .

So, we can replace the c by the limits of r and θ and this is the required transformed or changed integral from Cartesian coordinate system to polar coordinate system. And using this kind of formula where. So, here one can be able to transform or change the variable of an integral of a given double integral basically. So, let us work out and another example. So, this one is actually based on polar coordinate system.

(Refer Slide Time: 12:47)

Ex: Evaluate $\iint_E \sin \pi (x^2 + y^2) dx dy$, where E is $x^2 + y^2 \leq 1$.

Sol: Substitute $x = r \cos \theta$, $y = r \sin \theta$ where $r \in [0, 1]$ and $\theta \in [0, 2\pi]$.

$|J| = r$

$$I = \iint_E \sin \pi (x^2 + y^2) dx dy = \int_{r=0}^1 \int_{\theta=0}^{2\pi} \sin \pi (r^2 \cos^2 \theta + r^2 \sin^2 \theta) r dr d\theta$$

$$= \int_{r=0}^1 \int_{\theta=0}^{2\pi} \sin \pi r^2 r dr d\theta$$

So, its evaluate integral over the region E $\sin \pi x^2 + y^2 dx dy$ where E is given by $x^2 + y^2 \leq 1$, yes. So, here our domain of integration is basically this circle with radius one right. So, this is our region E . So, that is origin.

Now, we can see that here we have a $\sin \pi x^2 + y^2 dx dy$. If we want to evaluate using our traditional method like finding the limit for x which is 0 to 1 and the limit for y is $-\sqrt{1-x^2}$ to $\sqrt{1-x^2}$, then it might become a little bit difficult. However, if we do the change of variable from Cartesian to the polar coordinate system it might be beneficial.

So, let us see whether doing change of variable helps or not, that traditional method will always work, but its just that it might get tedious or it might get difficult at some point or the calculation basically. However, doing that the change of variable might make our life a little bit easier. So, let us see. So, substitute x equals to $r \cos \theta$ and y equals to $r \sin \theta$; where our r is running from 0 to 1 because the radius is 1 and θ will run from 0 to 2π right. So, where r belongs to 0 to 1 and θ belongs to 0 to 2π right ok.

Now, we know from the previous example, that the determinant of Jacobian or Jacobian determinant is basically r . So, here we can do the similar calculation which I am leaving up to the students and I am just going to use that answer, which is Jacobian determinant is r and r is 1. So, let us write just 1 and now we have $\sin \pi$ yes.

So, now we have integral I over the region E $\sin \pi x^2 + y^2 dx dy$. So, now, I am since I am transforming this whole integral into polar coordinate system, I can write the range for r which is 0 to 1, I can write range for θ which is 0 to 2π and then I have $\sin \pi x^2 + y^2$; $x^2 + y^2$ is $r^2 \cos^2 \theta + r^2 \sin^2 \theta$ and. So, this value will remain r^2 as it is, because we are taking r as a variable. So, this will become r^2 and $dr d\theta$. So, we take r^2 common. So, it will be $\cos^2 \theta + \sin^2 \theta$ then that value will be 1 and then we are left with r running from 0 to 1 θ running from 0 to 2π $\sin \pi r^2$ times $r dr d\theta$. So, here it is a very simple integral to evaluate we can substitute t is equals to r^2 .

(Refer Slide Time: 17:02)

$$\begin{aligned}
 &= \int_0^{2\pi} d\theta \int_0^1 \sin \pi r^2 r dr d\theta, \quad t = r^2 \Rightarrow dt = 2r dr \\
 &= \frac{1}{2} \int_0^{2\pi} d\theta \int_0^1 \sin \pi t dt \\
 &= -\frac{1}{2\pi} \int_0^{2\pi} [\cos \pi t]_0^1 d\theta \\
 &= -\frac{1}{2\pi} [-2] \int_0^{2\pi} d\theta = \frac{1}{\pi} \cdot 2\pi = 2
 \end{aligned}$$

So, putting t equals to r square and we separate these two integrals. So, 0 to 2π $d\theta$, and then we have r running from 0 to 1 $\sin \pi r^2 r dr d\theta$. So, let us put t equals to r square, then dt equals to $2r dr$ and then this whole thing will reduce to $\frac{1}{2}$ $\int_0^{2\pi} d\theta$ or I can write one more step.

So, this can be written as $\frac{1}{2} \int_0^{2\pi} d\theta$ and half integral from 0 to 1 $\sin \pi t dt$ and if I integrate then this will reduce to $\frac{1}{2} \int_0^{2\pi} d\theta$ $\int_0^1 \sin \pi t dt$ is $-\frac{1}{\pi} \cos \pi t$ and so, we will have $-\frac{1}{\pi} [\cos \pi t]_0^1$. So, when t is 0 yeah this is 1 .

So, we will have $-\frac{1}{\pi} [\cos \pi t]_0^1$ and this will be from 0 to 1 dt , now this can be written as $-\frac{1}{\pi} \int_0^{2\pi} d\theta$ $[\cos \pi t]_0^1$ this can be written as $-\frac{1}{\pi} \int_0^{2\pi} d\theta$ $(\cos \pi - \cos 0)$. So, basically $-\frac{1}{\pi} \int_0^{2\pi} d\theta$ $(-1 - 1)$ and we will have $-\frac{1}{\pi} \int_0^{2\pi} d\theta$ (-2) . So, this will be $\frac{2}{\pi} \int_0^{2\pi} d\theta$. So, the answer is ultimately 2 . So, here as you can see that initially we were given a very complicated integral to evaluate, but just by changing the variables; that means, changing the variables from Cartesian coordinate system to polar coordinate system, we can how to say calculate this whole integral in a lot more simpler manner.

So, this just in reduced to a $\sin \pi r^2 r dr d\theta$ and calculating that one, it was very easy because we substituted t equals to r square which will give you dt equals to $2r dr$, then you can adjust this factor here and the rest of the calculation will become fairly easy. Now not only always polar coordinates, but one can also try to how to say

transform them into a spherical coordinate system. If we have a triple integral, then you can also transform them to or the change of variable change the variables to spherical polar coordinate system, which we will learn later on.

So, this is a very handy tool actually to a calculate difficult integrals easily. Next we can we can work out and another example. So, an another example could be let us say prove that.

(Refer Slide Time: 20:46)

Ex: Prove that $\iint_E e^{-x^2-y^2} dx dy = \frac{\pi}{4} (1 - e^{-R^2})$, where E is the region defined by $x \geq 0, y \geq 0, x^2 + y^2 \leq R^2$.

Sol: Substitute $x = r \cos \theta, y = r \sin \theta$ where $0 \leq r \leq R$ and $0 \leq \theta \leq \frac{\pi}{2}$.

$$I = \iint_E e^{-(x^2+y^2)} dx dy = \iint_{E_1} e^{-(r^2 \cos^2 \theta + r^2 \sin^2 \theta)} r dr d\theta$$

$$= \int_{r=0}^R \int_{\theta=0}^{\frac{\pi}{2}} e^{-r^2} r dr d\theta$$

So, we will solve this example also in the similar fashion the way we did before edges that we are practicing one more problem. So, where E is the region defined by x greater or equal to 0, y greater or equal to 0 and x square plus y square is less or equal to R square. So, here there is something new actually in this problem.

So, first of all let us draw our region. So, if we draw our region, then we have a circle. So, let us draw this circle and that is our radius R; however, we are also given two separate conditions which is x is positive and y is positive; that means x is positive. So, we are not interested in this half and then y is positive. So, we are also not interested. So, x is positive so; that means, we are not interested in this half and then we have y is positive, then we are also not interested in this half. So, then our region is bounded by this circle and then these two lines x equals to 0 and y equals to 0. So, this is our region E right.

So, in this region of course, we have r is running from this small r is running from 0 to capital R up to the radius, but then θ is running from 0 to π by 0 only because we are not completing the whole circle we are just sticking to this half only. So, in that case we have θ running between 0 to π by 2. So, let us provide this transformation. So, substitute or put substitute or put x equals to $r \cos \theta$ and y equals to $r \sin \theta$, where r is running between 0 to capital R and θ is running between 0 to π by 2 right.

So, now we write this integral here, I equals to integral over the region E to the power minus x square plus y square $dx dy$. So, when we transform it to the region E_1 , we will write this region in E_1 in a minute we can write minus r square \cos square θ plus r square \sin square θ and then $dx dy$ will be converted into Jacobian Jacobian determinant, and then $dr d\theta$. So, this Jacobian is basically our r . So, we can write instead of this Jacobian we can simply write r .

So, now here we will replace this region E_1 with the limits for r and θ . So, r is running from 0 to capital R and θ is running from 0 to π by 2. In the integrand, we will take r square common and then we have \cos square θ plus \sin square θ . So, this will remain as it is and we will have $r dr d\theta$ right.

So, now I can substitute instead of r square, I can substitute t again and like what we did in the in the previous example we can also do the same thing here and ultimately we will end up with.

(Refer Slide Time: 24:55)

$$\begin{aligned}
 &= \int_0^{\pi/2} d\theta \int_0^R r e^{-r^2} dr \quad r^2 = t \Rightarrow 2r dr = dt \\
 &= -\frac{1}{2} \int_0^{\pi/2} e^{-r^2} \Big|_0^R d\theta \\
 &= -\frac{1}{2} \int_0^{\pi/2} [e^{-R^2} - 1] d\theta \\
 &= \frac{\pi}{2} \cdot \frac{1}{2} [1 - e^{-R^2}] \\
 &= \frac{\pi}{4} [1 - e^{-R^2}]
 \end{aligned}$$

So, we will first write $\int_0^{\pi/2} \int_0^R e^{-r^2} r \, dr \, d\theta$ then integral from 0 to capital R e^{-r^2} to the power minus r^2 dr and then we substitute for $r^2 = t$ and then we transform this whole thing into function of t to the power minus t and then this will ultimately give us e^{-R^2} to the power minus R^2 integral from 0 to capital R dr and we will have sorry $d\theta$ and we will have minus half at the front yeah.

So, this will be $\frac{1}{2} \int_0^{\pi/2} \int_0^R e^{-r^2} r \, dr \, d\theta$ it was to dt and this can be written as minus half integral from 0 to $\pi/2$ this will be e^{-R^2} to the power minus R^2 minus e^{-0} so, basically 1 and then $d\theta$. So, this will be $\pi/2$ times half times 1 minus e^{-R^2} to the power minus R^2 . So, ultimately we will have $\pi/4$ times one minus e^{-R^2} to the power minus R^2 and I believe this is what we needed to prove yes.

So, see initially it was a little bit how to say complicated in a way to evaluate this integral, but just using some transformation which was how to say polar coordinate system which transferred this Cartesian coordinate system into a polar coordinate system with we were able to reduce this whole $e^{-x^2 - y^2}$ into a fairly simple method of substitution integral and by doing that substitution our required result will be this.

And of course, using these transformation of course, makes life quite easy and there will be a lot of situations where we come where we come across a very complicated integral double integral, but just using some simpler transformation we can be able to reduce that complicated integral into a fairly simple one and this is one such example. We will we will restrict ourselves to practicing examples on this topic up to here, in the next class we will start with change of order of integration. So, today we saw a change of variables using Jacobian transformation, in the next class we will see change of order of integration and triple integral and that we conclude this section as well. So, I look forward to your next class.

Thank you.
