**Directional Derivatives (Concept & Few Results)**

Hello, students. So, in the previous class, we introduced the concept of level surfaces and we also saw two results that when you have a level surface on a region  $R$ , then at every point of  $R$  only one and only one level surface and that can pass through that point that that point in our and we also saw another result which says that gradient of a function is perpendicular to the surface  $f(x, y, z) = c$ .

So, now that we have those two basic results today we will start with the concepts of directional derivative and we will try to work out few examples based on directional derivative. So, we will start with a formal definition what do they actually mean.

(Refer Slide Time: 01:06)

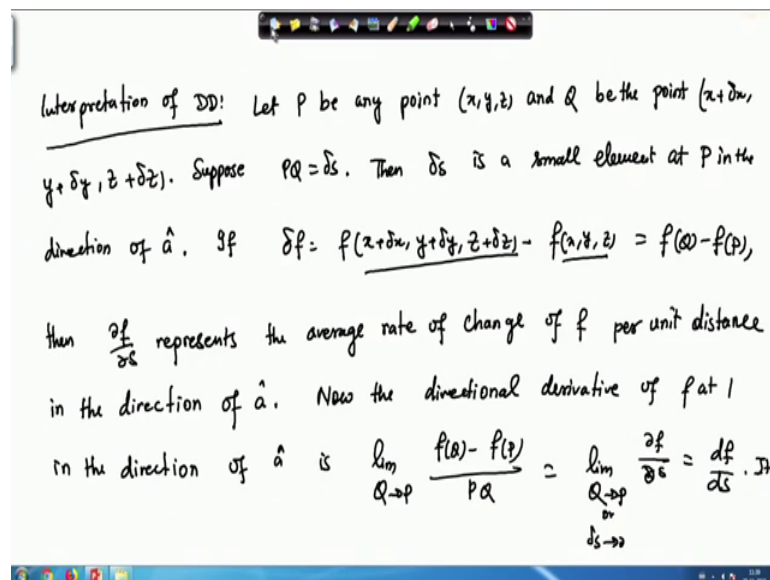

So, directional derivative of a scalar function, alright. So, the formal definition goes like this let  $f(x, y, z)$  defines a scalar field in a region  $R$  and let  $P$  be any point in this region and suppose  $Q$  is a point in this region in the neighbourhood in the neighbourhood in the neighbourhood bour in the neighbourhood of the of the point  $P$  of the point  $P$  in the direction of a given unit vector.

So, this is very important we also we always have to have a unit vector when we are calculating the directional derivative of a given unit vector a cap. Then, limit  $Q$  tends to  $P$   $f(Q) - f(P)$  divided by  $PQ$  if it exists is called the directional derivative of  $f$  at the point at the point  $P$  in the direction of a cap in the direction of a cap.

So, basically what it means is you have a you have a point  $P$  on a on a on a surface  $f(x, y, z)$  it goes to  $C$  in a region  $R$  and then you have another point let us say  $Q$  in the neighbourhood of the point  $P$ . So, when  $P$  when  $Q$  approaches to  $P$  then if this limit exists then the then this limit is actually called as the directional derivative in the direction of this unit vector a cap. So, this point  $Q$  which we have chosen so, this point  $Q$  is of course, is a point in the neighbourhood is of course, a point in the neighbourhood of the point  $P$ , but it is also in the direction of a unit vector a cap.

So, it is a point in the direction of in the direction of a unit vector a cap and then we calculate this limit and if this limit exists, then we say that the then we say that this limit is actually the directional derivative is the directional derivative of the function  $f$  at the point  $P$  in the direction of a cap, alright.

(Refer Slide Time: 05:32)

So, basically what it means is what it means is so, physical meaning or what it means is interpretation we can write interpretation of directional derivative. So, I write it as DD. So, interpretation is let  $P$  be any point. So, what we are saying is let  $P$  be any point  $x, y, z$  and  $Q$  be the point  $x$  plus delta  $x, y$  plus delta  $y$  and  $z$  plus delta  $z$  and suppose,  $PQ$  which

is a very small arc length is  $\Delta S$ . So, it is a very small arc length and we assume that the length is  $\Delta S$  alright.

So, suppose  $PQ$  is equals to  $\Delta S$  then  $\Delta S$  is a small element is a small element at  $P$  in the direction with a small element at  $P$  in the direction of a cap and if  $\Delta f$  is equals to  $f(x + \Delta x, y + \Delta y, z + \Delta z) - f(x, y, z)$  is equals to. So, this is our point  $Q$  this is our point  $P$ . So,  $f(Q) - f(P)$  then  $\Delta f$  by  $\Delta S$  represents the average rate of change the average rate of change of  $f$  per unit distance in the direction of a cap.

And, now, the directional derivative of  $f$  at the point  $P$  in the direction of a cap is basically  $\lim_{Q \rightarrow P} \frac{f(Q) - f(P)}{PQ}$  is equals to basically  $\lim_{Q \rightarrow P} \frac{\Delta f}{\Delta S}$  or  $\Delta S$  goes to 0 or we can write  $\Delta S$  goes to 0  $\Delta f$  by  $\Delta S$ . So, this is nothing, but our  $df/dS$  because when  $\Delta S$  goes to 0, this whole thing we will converge to  $df/dS$ .

(Refer Slide Time: 09:04)

represents the rate of change of  $f$  w.r.t. distance at  $P$  in the direction of  $\hat{a}$ .

$f(x, y, z) = \frac{df}{ds}$  ✓

Thm 1: The directional derivative of a scalar field  $f$  at a point  $P(x, y, z)$  in the direction of a unit vector  $\hat{a}$  is given by

$$\frac{df}{ds} = \nabla f_p \cdot \hat{a}$$

And, it represents so, basically it represents the rate of change of the rate of change of  $f$  with respect to distance at  $P$  in the direction of a cap which is a unit vector. So, what it does what it means physically is that we have two neighbouring points on the surface  $f(x, y, z) = C$  and then that is small increment in the function  $f$  or in the in from the point  $P$  to  $Q$  is denoted by  $\Delta f$  and  $\Delta S$ . So, that a small increment in the function  $f$

we write it as  $\Delta f$  which is basically  $f(Q) - f(P)$  and the small element which is this  $PQ$  is basically  $\Delta S$ .

So,  $\Delta f$  by  $\Delta S$  when  $\Delta S$  goes to 0 is actually the average rate of change of  $f$  per unit distance. So, how much how much the function is changing how it is changing per unit distance is given by  $\frac{\Delta f}{\Delta S}$  in the direction of the vector  $\hat{a}$ .

So, we always have a unit vector along which we are calculating the rate of change of the function  $f$  and the directional derivative of the function  $f$  at  $P$  at this point  $P$  is basically when limit  $Q$  goes to  $P$  we write  $\frac{f(Q) - f(P)}{PQ}$  which is basically our  $\frac{\Delta f}{\Delta S}$  and at the point  $P$  we have this we have this  $\Delta S$  this surface element is that a small element at the point  $P$  in the direction of  $\hat{a}$ . So, that is what we are calculating here. So, this is basically our rate of change of the function  $f$  per unit distance in the direction of  $\hat{a}$  at the point  $P$ .

So, this is represent the rate of change of the function  $f$  with respect to distance or per unit distance at the point  $P$  in the direction of  $\hat{a}$ . So,  $\hat{a}$  is a unit vector at the point  $P$  and this  $\frac{df}{dS}$  is actually denoting our rate of change of the function  $f$ . So, this is what we mean physically by the directional derivative. So, at a certain point you have a unit vector and you need to calculate the rate of change of that function along that unit vector. So, that is that is what simple and an in simple words it mean.

So, you have a unit vector at a point  $P$  on a surface  $f(x, y, z) = C$ . So, your directional derivative is actually the rate of change of that function  $f(x, y, z)$  with respect to distance of course, in the direction of that unit vector at the point  $P$ . So, or whichever point it is where you are calculating the directional derivative and this is what we mean physically or the physical interpretation of the direction and derivative.

Now, that we have stated  $\frac{df}{dS}$  is basically that rate of change of  $f$  with respect to distance how do we calculate the directional derivative do we really have to differentiate  $f(x, y, z) = c$ . So, do we really have to differentiate  $f(x, y, z) = c$  as  $\frac{\Delta f}{\Delta S}$  or do we have to calculate  $\frac{df}{dS}$  to calculate the directional derivative or is there any other formula to calculate the directional derivative so, that we will now prove, in terms of a small theorem. So, whether we calculate this thing or whether there is some other tool that will help us calculate the directional derivative. So, that we are going to the there some that is something we are going to see now.

So, let me put a small theorem here. So, today it is theorem 1, and it says that the directional derivative of a scalar field  $f$  at a point  $P(x, y, z)$  in the direction of a unit vector  $\hat{a}$  is given by  $\frac{df}{ds}$  is equals to gradient of  $f$  at the point  $P$  times  $\hat{a}$ . So, we have to calculate the gradient of the function at the point  $P$ . So, I can put a  $P$  here and that basically says that the gradient of the function has to be calculated at the point  $P$  times the unit vector  $\hat{a}$ .

So, that means, instead of calculating  $\frac{df}{ds}$  we can just using this theorem the directional derivative of the function  $f$  at the point  $P$  in the direction of  $\hat{a}$  is given by gradient of  $f$  at the point  $P$  dot product with  $\hat{a}$ . So, this  $\frac{df}{ds}$  is equals to this. So, this  $\frac{df}{ds}$  is equals to gradient of  $f$  at the point  $P$  times a  $\hat{a}$ .

So, this is a very small result and we will try to prove that and see how this thing this  $\frac{df}{ds}$  equals to this gradient of  $f$  at  $P$  times a  $\hat{a}$ .

(Refer Slide Time: 14:45)

Pr: Let  $f(x, y, z)$  be a scalar field in the region  $R$  and let  $P(x, y, z) \in R$ , then

$\vec{OP} = \vec{r} = x\hat{i} + y\hat{j} + z\hat{k}$ . If  $s$  denotes the distance of  $P$  from some fixed point  $A$  in the direction of  $\hat{a}$ , then  $\Delta x$  denotes a small element of  $P$  in the direction of  $\hat{a}$ . Therefore  $\frac{d\vec{r}}{ds}$  is a unit vector at the  $P$  in this direction, i.e.,

$$\frac{d\vec{r}}{ds} = \hat{a}.$$

But  $\vec{r} = x\hat{i} + y\hat{j} + z\hat{k} \Rightarrow \frac{d\vec{r}}{ds} = \frac{dx}{ds}\hat{i} + \frac{dy}{ds}\hat{j} + \frac{dz}{ds}\hat{k} = \hat{a}$

Now,  $\vec{\nabla} f \cdot \hat{a} = \frac{\partial f}{\partial x} a_1 + \frac{\partial f}{\partial y} a_2 + \frac{\partial f}{\partial z} a_3 = \frac{\partial f}{\partial x} \frac{dx}{ds} + \frac{\partial f}{\partial y} \frac{dy}{ds} + \frac{\partial f}{\partial z} \frac{dz}{ds}$

So, the proof or the solution. So, let  $f(x, y, z)$  be a scalar field. So, let  $f(x, y, z)$  be a scalar field in the region  $R$  and let  $P(x, y, z)$  be any arbitrary point in the region  $R$ . So,  $P(x, y, z)$  belongs to  $R$ . So, then I can write  $OP$  or the position vector of the point  $P$  is equals to  $x\hat{i} + y\hat{j} + z\hat{k}$ , alright.

Now, if  $s$  denotes the distance of  $P$  from some fixed point  $A$  in the direction in the direction of  $\hat{a}$  then  $\Delta x$  denotes a small element denotes a

small element at P in the direction of a cap and therefore,  $dr dS$  is a unit vector at the point P in this direction that is  $dr dS$  is equals to a cap.

So, what we are doing is we are assuming the distance of P from any fixed point A in the direction of a cap. So, in the direction of a cap we assume any arbitrary point let us say A, and S denotes the distance and then in that case a small element or a small increment in the point P in the direction of a, then that small increment is denoted by  $\Delta x$ . So, if we are moving along the surface and from P to let us say Q or P to a we are going then that small increment is basically our  $\Delta x$  then in the direction and then in the direction of a of course,.

So, therefore,  $dr dS$  basically the rate of change of R with respect to the distance is a unit vector in the direction of this in the direction of this unit vector a cap. So, this basically  $dr dS$  is a unit vector at the point P in the direction of a cap, alright. So, but our r is equals to  $x i$  plus  $y j$  plus  $z k$ . So, from here our  $dr dS$  will be  $dx dS$  times  $i$   $dy dS$  times  $j$  and  $dz dS$  times  $k$  alright.

So, now our gradient of f times a cap, what is this? So, this one will be  $\frac{\partial f}{\partial x}$  times a 1 and then  $\frac{\partial f}{\partial y}$  times a 2 and  $\frac{\partial f}{\partial z}$  times a 3 right. So, this a actually. So, this a 1, a 2, a 3 will be actually we can write it now. So,  $dr dS$  is basically  $dx dS$  from here  $dy dS$  and  $dz dS$ . Now,  $dr dS$  is equals to a cap. So, that means, if I write this one as a cap, so, the components of a cap will be a 1, a 2, a 3.

So, a 1 equals to  $dx dS$ , a 2 equals to  $dy dS$  and a 3 equals to  $dz dx$ . So, I am substituting them here. So,  $\frac{\partial f}{\partial x}$  times  $dx dS$   $\frac{\partial f}{\partial y}$  times  $dy dS$  and  $\frac{\partial f}{\partial z}$  times  $dz ds$ . So, since  $dz$  and  $\frac{\partial z}{\partial x}$  they are a small element. So, we can cancel this  $\frac{\partial z}{\partial x}$  the  $\frac{\partial z}{\partial x}$   $\frac{\partial z}{\partial x}$   $\frac{\partial z}{\partial x}$ . So, then this will be  $df$  and  $\frac{\partial f}{\partial S}$   $\frac{\partial f}{\partial y}$  and then  $\frac{\partial f}{\partial S}$ . So,  $\frac{\partial f}{\partial S}$   $\frac{\partial f}{\partial y}$  and then  $\frac{\partial f}{\partial S}$  and then this one again will be  $\frac{\partial f}{\partial S}$ .

(Refer Slide Time: 20:38)

$$= \frac{1}{ds} \left( \frac{\partial f}{\partial x} dx + \frac{\partial f}{\partial y} dy + \frac{\partial f}{\partial z} dz \right)$$
$$= \left( \frac{df}{ds} \right)$$
$$\Rightarrow \frac{df}{ds} = \nabla_P f \cdot \hat{a} \rightarrow \text{formula to calculate DD.}$$

So, ultimately if I multiply so, if I so, ultimately so, what I am trying to say is that we can write it something like this  $1$  by  $ds$  and then what I am trying to say is  $\nabla f \cdot \hat{a}$  times  $dx$   $\nabla f \cdot \hat{a}$  times  $dy$  and  $\nabla f \cdot \hat{a}$  times  $dz$ . So, this is what we can do here and now this is nothing, but our  $df$ . So, that is from differential calculus this is our  $df$ . So, I can write it as  $df/ds$ . Now, we know that  $df/ds$  is the directional derivative at the point  $P$  in the direction of  $\hat{a}$ . So, that is what physically it means from the definition of directional derivative.

So, this is our directional derivative of the function  $f$  at the point  $P$  in the direction of  $\hat{a}$ . So, what we have is we have  $df/ds$  is equals to gradient of  $f$  times  $\hat{a}$  and if we want to calculate a directional derivative, then we can calculate the gradient of the function  $f$  at the point  $P$ , this is very important times the unit vector  $\hat{a}$ . So, this is the required formula to calculate directional derivative, alright. So, and this is what we wanted to prove.

So, the direction derivative of a scalar field at the point  $P$  in the direction of a unit vector  $\hat{a}$  is given in this fashion and just assuming some basic results from the differential calculus and not assuming, but using those results from the differential calculus we can be able to show that the direction derivative  $df/ds$  is equals to gradient of  $f$  at the point  $P$  times  $\hat{a}$  and this is what this is what is equal to our directional derivative, alright.

So, now we will try to work out few examples before we go to our next topic. So, let us calculate the directional derivative we will work out few examples on level surfaces, alright.

(Refer Slide Time: 22:47)

Ex1: Find a unit normal vector to the level surface  $x^2y + 2xz = 4$  at the point  $P(2, -2, 3)$ .

Sol<sup>n</sup>: Here the eq<sup>n</sup> of the level surface is  $f(x, y, z) = x^2y + 2xz = 4$ , and we know that  $\vec{\nabla}f$  is  $\perp$  to the surface  $f$ . Then,

$$\vec{\nabla}f = \vec{\nabla}(x^2y + 2xz) = (2xy + 2z)\hat{i} + x^2\hat{j} + 2x\hat{k}$$

$$\vec{\nabla}f \Big|_{P(2, -2, 3)} = [2 \cdot 2 \cdot (-2) + 2 \cdot 3]\hat{i} + [2^2]\hat{j} + 2 \cdot 2\hat{k} = -2\hat{i} + 4\hat{j} + 4\hat{k}$$

So, in the previous class we started with level surfaces and in today's class we started with directional derivative. So, we will work we will try to solve the examples on both of these two topics. So, the first one is first example find a unit normal find a unit normal vector to the level surface  $x$  square  $y$  plus  $2xz$  equals to  $4$  at the point  $2$ , minus  $2$ , and  $3$ . So, our given level surfaces  $x$  square plus  $x$  square  $y$  plus  $2x$  then equals to  $4$  and we have to calculate the unit normal vector at the point. So, let us put a  $P$  here at the point  $P$   $2$ , minus  $2$ , and  $3$ .

So, what we are going to do? First of all from the results on a level surfaces we know that gradient of  $f$  is a normal to this level surface. So, here it says that find a unit normal. So, we have to find a normal to this surface given here and then dividing it with its magnitude will give us the unit normal, alright.

So, those two steps are clear. So, first of all we have to calculate its gradient. So, here the equation of the level surface is  $f(x, y, z) = x^2y + 2xz = 4$ , alright and we know that gradient of  $f$  is perpendicular or normal to the surface  $f$ . Then, first of all we calculate the gradient of  $f$  gradient of  $f$  would be gradient of  $x^2y + 2xz$  set of course, gradient of  $4$  will be  $0$ . So, calculating this one is not difficult. So,  $\text{del del } x$  are

$2xy$  plus  $2z$  times  $i$  well  $\text{del del } y$  would be  $x^2j$  and  $\text{del del } z$  will be  $2xk$ . So, this is the required gradient of  $f$ .

And, now, the gradient of  $f$  at the point  $P$  and  $P$  is  $2$ , minus  $2$ , and  $3$ . So, if I substitute then it will be  $2$  times  $2$  minus  $2$  plus  $2$  times  $3$  times  $i$  plus  $x^2$  which is  $2^2$  times  $j$  and this one is  $2$  times  $2$ ,  $k$ . So, this will be ultimately an on minus  $2i$  plus  $4j$  plus  $4k$  and therefore, this gradient of  $f$ .

(Refer Slide Time: 26:41)

The image shows a whiteboard with handwritten mathematical work. At the top, it says  $(-2\hat{i} + 4\hat{j} + 4\hat{k})$  is normal to the surface  $f(x, y, z) = c$ . Below this, an arrow points to the equation  $\hat{n} = \frac{-2\hat{i} + 4\hat{j} + 4\hat{k}}{\sqrt{4 + 16 + 16}} = \frac{-2\hat{i} + 4\hat{j} + 4\hat{k}}{6}$  is a unit normal to the surface  $f(x, y, z) = c$ .

So, the gradient of  $f$  or minus of  $2i$  plus  $4j$  plus  $4k$  is normal, oh sorry, is normal or perpendicular to the surface is normal or perpendicular to the surface  $f(x, y, z) = c$  alright, but we have to find out a unit normal or unit vector perpendicular to this. So, to give the unit normal we write it as  $4j$  plus  $4k$  and then we divide it by its magnitude so; that means, minus to a square which is  $4^2$  plus  $4^2$  a square is  $16$  plus  $16$ .

So, ultimately this will be minus  $2i$  plus  $4j$  plus  $4k$  and then this will be  $32$  plus  $40$ . So, we can write  $2\sqrt{10}$  is a unit normal or unit vector a unit normal or unit vector perpendicular to the surface  $f(x, y, z) = c$  and  $f(x, y, z)$  is basically our  $x^2y$  plus  $2xz$  equals to equals to  $4$ . So, that  $c$  is  $4$ .

So, this is the required this is the weight this one is a  $16$ ,  $16$ ,  $32$  plus  $4$ ,  $36$  ok. So, this has to be  $6$  it is not  $40$ , it is a  $36$ . So, it will be  $6$ . So, this is the required unit normal

perpendicular to the surface  $f(x, y, z) = c$  and you see we had an equation of a level surface here in this example we had a question of a level surface.

So, we write we wrote this level surface as  $f(x, y, z) = c$  and then we had to calculate the gradient because gradient is a vector normal to the level surface  $f(x, y, z) = c$  and then we calculated the gradient at the point P and then we divided it with its magnitude and that gave us the unit normal or unit vector perpendicular to the surface  $x^2 + y + 2xz = 4$  at the point  $(2, -2, 3)$  you also have to make sure whether this point lies on that level surface or not because we can do all this calculation but, always make sure that this point lies there.

So, if I substitute there then this will be 4. So,  $4 - 8 - 8 = -12$  and that will be  $-12$  to also of course, this point lies on the level surface. So, before you calculate anything you also have to make sure the given point P lies on the level surface or not. So, here in this case it does lie on that level surface and therefore, the gradient of  $f$  is actually normal to that level surface at the point P and if you divide it with its magnitude then that is the unit normal; here I can write it as  $\nabla f$ , alright.

So, today we saw one example motivated from the level surface and unit normal. In our next class we will continue with the examples on level surfaces and directional derivative just to make the concepts clear and I look forward to you in your next class.

Thank you.
