Lecture – 19
Lower Bounds for Variance – V

In the last class I have discussed one example, let me continue with that example.

(Refer Slide Time: 00:26)

Example: Let $X_1, \dots, X_n \sim N(0, \sigma^2)$
 Consider the estimation of σ .
 $f(x; \sigma) = \frac{1}{\sigma\sqrt{2\pi}} e^{-x^2/2\sigma^2}$, $x \in \mathbb{R}, \sigma > 0$.
 $\log f(x; \sigma) = -\log \sigma - \frac{1}{2} \log 2\pi - \frac{x^2}{2\sigma^2}$
 $\frac{\partial \log f}{\partial \sigma} = -\frac{1}{\sigma} + \frac{x^2}{\sigma^3} = \frac{1}{\sigma} \left(\frac{x^2}{\sigma^2} - 1 \right)$
 $E \left(\frac{\partial \log f}{\partial \sigma} \right)^2 = \frac{1}{\sigma^2} E \left(\frac{x^2}{\sigma^2} - 1 \right)^2 = \frac{2}{\sigma^2}$
 $I_X(\sigma) = \frac{2n}{\sigma^2}$, FRC LB for $\sigma = \frac{\sigma^2}{2n}$.

We have a random sample from normal 0 sigma square distribution. And we are considering the estimation of sigma in place of sigma square. So, what I showed in the last class is that the Rao Cramer lower bound lower bound for estimation of sigma is sigma square by 2 n. Now, I will propose two estimators for the estimation of sigma and we will consider their variances and then we will see whether the FRC lower bound for them is attained or not. In fact, we have seen that for sigma square it is attained; now sigma is not a linear function of sigma square. Therefore, this bound may not be will not be attained. however, we will consider 2 examples.

(Refer Slide Time: 01:18)

Lecture- 10

Consider $V_X = \alpha \sum_{i=1}^n |X_i|$

$$E|X_i| = \int_{-\infty}^{\infty} |x| \frac{1}{\sigma\sqrt{2\pi}} e^{-x^2/2\sigma^2} dx = 2 \int_0^{\infty} x \cdot \frac{1}{\sigma\sqrt{2\pi}} e^{-x^2/2\sigma^2} dx = \frac{2\sigma}{\sqrt{2\pi}}$$

So $E(V_X) = \frac{2n\sigma}{\sqrt{2\pi}} \alpha = \sigma \Rightarrow \alpha = \frac{1}{n} \sqrt{\frac{\pi}{2}}$

So $T_1 = \frac{1}{n} \sqrt{\frac{\pi}{2}} \sum_{i=1}^n |X_i|$ is an unbiased estimator of σ .

$$\text{Var}(T_1) = \frac{\pi}{2n^2} \cdot n \text{Var}(|X_i|) = \frac{\pi}{2n} (E X_i^2 - (E|X_i|)^2) = \frac{\pi}{2n} \left(\sigma^2 - \frac{2\sigma^2}{\pi} \right)$$

$$= \frac{(\pi-2)}{2n\pi} \sigma^2 > \frac{\sigma^2}{2n}$$

So T_1 does not achieve FRCLB though T_1 is unbiased and consistent.

Further define $W_B = \beta \left(\sum X_i^2 \right)^{1/2}$.

NPTEL

So, let me take the first example. Consider an estimator of the form say V alpha is equal to alpha into sigma modulus of X_i , i is equal to 1 to n . Now, if you consider say expectation of modulus x_i , that is equal to integral from minus infinity to infinity. Modulus x 1 by sigma root 2 pi e to the power minus x square by 2 sigma square dx .

Now this is an even function so this will become 2 times 0 to infinity x 1 by sigma root 2 pi e to the power minus x square by 2 sigma square. Now this can be easily evaluated because derivative of e to the power minus x square by 2 sigma square is e to the power minus x square by 2 sigma square into x by sigma square. So, if you evaluate this integral this turns out to be simply 2 sigma divided by root 2 pi.

So, if we consider expectation of V alpha that will be equal to twice n sigma by root 2 pi alpha. Now, if we want that V alpha be an unbiased estimator of sigma then we substitute this equal to sigma; that gives the value of alpha is equal to 1 by n root pi by 2. So, what we are getting is that let me call this estimator as T_1 , by substituting alpha is equal to this value.

That is 1 by n root pi by 2 sigma modulus of X_i this is unbiased estimator of sigma. Let us look at the variance of T_1 . So, what is variance of T_1 ? Variance of T_1 will become pi by 2 n square into n times variance of modulus X_i ; now this becomes pi by 2 n . Now variance of X_i is expectation, modulus X_i square that is expectation of X_i square and minus expectation of modulus X_i whole square.

Now, since we have considered here the normal 0 sigma square. So, expectation of X_i square is nothing the variance that is sigma square. So, this value is equal to sigma square. And expectation of modulus X_i we have just now calculated. So, if we substitute the square of that I get 2 sigma square by pi. So, this can be written as pi minus 2 by. So, what I am doing is a larger system pi minus 2 by pi and then $2n$ is there. So, $2n$ pi sigma square. Now, this can be shown that this is bigger than sigma square by $2n$.

Similarly, so we can say that T_1 does not achieve FRC lower bound. And if you look at the estimator here see the variance is certain term divided by n . So, as n tends to infinity this goes to 0 and it is unbiased. so, this is unbiased T_1 is unbiased as well as consistent. Let me define another estimator here let me call it say W beta that is equal to beta times sigma X_i square to the power half.

(Refer Slide Time: 06:04)

Handwritten mathematical derivation on a blue background:

$$U = \frac{\sum X_i^2}{\sigma^2} \sim \chi_n^2, \quad E U^{1/2} = \frac{\sqrt{2} \Gamma(\frac{n+1}{2})}{\Gamma(\frac{n}{2})}$$

$$E(W_\beta) = \beta \cdot \frac{\sqrt{2} \Gamma(\frac{n+1}{2})}{\Gamma(\frac{n}{2})} \sigma = \sigma \Rightarrow \beta = \frac{\Gamma(\frac{n}{2})}{\sqrt{2} \Gamma(\frac{n+1}{2})}$$

So $T_2 = \frac{\Gamma(\frac{n}{2})}{\sqrt{2} \Gamma(\frac{n+1}{2})} (\sum X_i^2)^{1/2}$ is also an unbiased estimator of σ .

$$\text{Var}(T_2) = \frac{1}{2} \left\{ \frac{\Gamma(\frac{n}{2})}{\Gamma(\frac{n+1}{2})} \right\}^2 \text{Var}\left\{ (\sum X_i^2)^{1/2} \right\}$$

$$= \frac{1}{2} \left\{ \frac{\Gamma(\frac{n}{2})}{\Gamma(\frac{n+1}{2})} \right\}^2 \left[E(\sum X_i^2) - \left(E(\sum X_i^2)^{1/2} \right)^2 \right]$$

$$= k \left[n - 2 \left(\frac{\Gamma(\frac{n+1}{2})}{\Gamma(\frac{n}{2})} \right)^2 \right] \sigma^2 = \left[\frac{n}{2} \left\{ \frac{\Gamma(\frac{n}{2})}{\Gamma(\frac{n+1}{2})} \right\}^2 - 1 \right] \sigma^2$$

can be shown that $\frac{\Gamma(\frac{n}{2})}{\Gamma(\frac{n+1}{2})} > \sigma_{T_2}^2 > \sigma_{T_1}^2$. $\text{Var}(T_2) < \text{Var}(T_1)$.

Now, if you want to evaluate the expectation of this we can consider. If X_i 's follow normal 0 sigma square then X_i by sigma that will follow normal 0 1. So, the sum of squares of a standard normal variables when they are independent is a chi square random variable. So, we get here that U is equal to sigma X_i square by sigma square this follows chi square distribution on n degrees of freedom.

Now if I have a chi square then expectation of U will become root 2 gamma n plus 1 by 2 by gamma n by 2 . Therefore, expectation of W beta that turns out to be beta times root 2 and here we will get gamma n plus 1 by 2 by gamma n by 2 sigma. Once again if I

want this to be unbiased then I equate it to sigma ; that means, beta should be equal to gamma n by 2 divided by root 2 gamma n plus 1 by 2..

So, T 2 is equal to gamma n by 2 by root 2 gamma n plus 1 by 2 sigma X i square to the power half this is also an unbiased estimator of sigma. Let us look at what is variance of T 2; variance of T 2 is half gamma n by 2 divided by gamma n plus 1 by 2 whole square into variance of sigma X i square to the power half. Now, variance of sigma X i square to the power half. That is expectation of sigma X i square minus expectation of sigma X i square whole square; sigma X i square to the power half whole square.

Now these terms we have already calculated so that becomes let me call it this some constant n minus twice gamma n plus 1 by 2 by gamma n by 2 whole square sigma square. That we can write after simplification as n by 2 gamma n by 2 divided by gamma n plus 1 by 2 whole square minus 1 sigma square. It can be shown that variance of T 2 is greater than sigma square by 2 n. And variance of T 2 is less than variance of T 1. In fact, one can show that this also goes to 0 as n tends to infinity.

(Refer Slide Time: 09:29)

So $T_2 = \frac{\sqrt{n_2}}{\sqrt{2} \sqrt{\frac{n+1}{2}}} (\sum X_i^2)^{1/2}$ is also an unbiased estimator of σ .

$$\text{Var}(T_2) = \frac{1}{2} \left\{ \frac{\sqrt{n_2}}{\sqrt{\frac{n+1}{2}}} \right\}^2 \text{Var} \left\{ (\sum X_i^2)^{1/2} \right\}$$

$$= \frac{1}{2} \left\{ \frac{\sqrt{n_2}}{\sqrt{\frac{n+1}{2}}} \right\}^2 \left[E(\sum X_i^2) - \left\{ E(\sum X_i^2)^{1/2} \right\}^2 \right]$$

$$= k \left[n - 2 \left(\frac{\frac{n+1}{2}}{\sqrt{n_2}} \right)^2 \right] \sigma^2 = \left[\frac{n}{2} \left\{ \frac{\sqrt{n_2}}{\sqrt{\frac{n+1}{2}}} \right\}^2 - 1 \right] \sigma^2$$

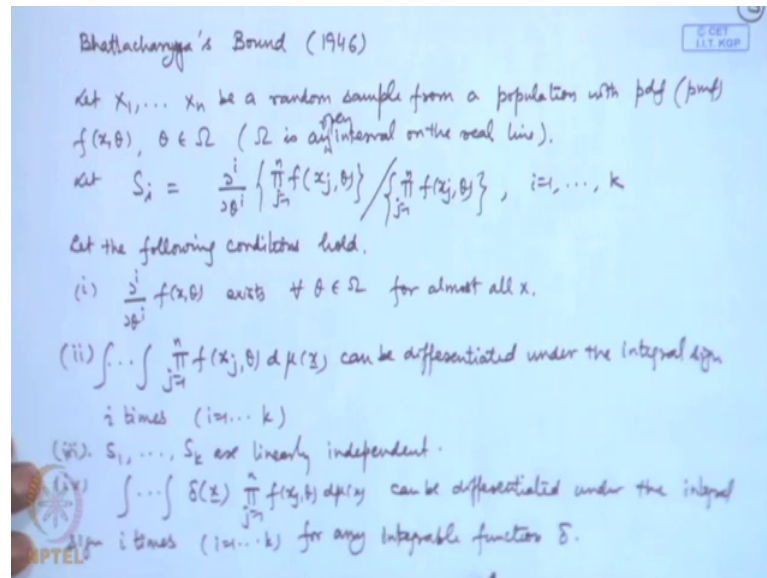

It can be shown that $\frac{\sigma^2}{\text{Var}(T_2)} > \sigma^2_{/2n}$. $\text{Var}(T_2) < \text{Var}(T_1)$.

T_2 is more efficient than T_1

So, T 2 is more efficient than T 1. Now we have discussed in detail one lower bound for the variance of an unbiased estimator and this lower bound takes into account one derivative of the log of the density function.

Now, naturally there is a question whether one can further sharpen it or whether we can extended to multi parameter case or whether if the regulatory conditions are not satisfied; then this will be true or not. Fortunately in all the directions the extensions of this result have been done. So, let me discuss this here the first of this is known as Bhattacharyya bound.

(Refer Slide Time: 10:30)

So, this was proposed by a Bhattacharyya in 1946. Now, in the fisher Rao Cramer lower bound we had considered first order derivative and of course, second order derivatives condition was assumed. However, in the Bhattacharyya bound higher order derivatives are used. And therefore, we have to make the assumptions accordingly. So, once again as in the Rao Cramer lower bound let us consider the regularity conditions in the same way.

So, we have a random sample let X_1, X_2, \dots, X_n be a random sample from a population. Now, again it may have a probability density function or probability mass function say $f(x, \theta)$; θ belonging to Ω , where Ω is an interval on the real line.

Let us define S_i to be i th order derivative of the joint distribution divided by the joint distribution. You compare it with the Rao Cramer lower bound in the Rao Cramer lower bound we had first order derivative here. Now, I am defining higher order derivatives also. Because in the first order derivative it will become $\frac{\partial}{\partial \theta}$ of the density divided by the density that is $\frac{\partial}{\partial \theta} \log$ of that. But here it is higher order here.

So, i is equal to 1, 2 and so on suppose I am assuming up to order k let the following conditions hold. So, we have already assumed that the parameter spaces and interval in the real line let us consider open interval. Let us assume that the i th order derivative of the density exists for all θ for almost all x ; by almost all x means that the set where this is not existing will have probability 0.

The density function once again I am writing this is a manifold integral and this is a generalized integral; that means, it takes care of the discrete case also in that case this will be summation. This can be differentiated under the integral sign at least i times. Let us define S_i as this term. Then we assume that S_1, S_2, S_k are linearly independent.

By linearly independent means that none of their can be expressed as function as linear combination of the others. And this manifold integral this also can be differentiated under the integral sign i times; i is equal to 1 to k for any integrable; that means, this should exist for any integrable function δ .

(Refer Slide Time: 15:23)

Let $\lambda_{ij} = \text{Cov}(S_i, S_j), i, j = 1, \dots, k$
 $\lambda_{ii} = \text{Var}(S_i), i = 1, \dots, k$

Let $\Lambda = [\lambda_{ij}]_{i, j = 1, \dots, k}$
 Let λ^{rs} denote the rs th term of the matrix Λ^{-1} and $\eta_i = \text{Cov}(T, S_i) = \frac{d g}{d \theta^i}, i = 1, \dots, k$

where $E_{\theta} T(X) = g(\theta), \eta = (\eta_1, \dots, \eta_k)$.

Then Bhattacharyya's bound is:

$$\text{Var}_{\theta}(T) \geq \eta' \Lambda^{-1} \eta = \sum_r \sum_s \lambda^{rs} \frac{d^r g}{d \theta^r} \cdot \frac{d^s g}{d \theta^s}$$

(For $k=1$, this will reduce to FRLB).

Proof: $E_{\theta} T(X) = g(\theta) \quad \forall \theta \in \Theta$

$$= \int \dots \int T(x) \left\{ \prod_{j=1}^k f(x_j, \theta) \right\} d\mu(x) = g(\theta) \quad \forall \theta \in \Theta \quad \dots (1)$$

Let us define; let us define say λ_{ij} to be the covariance between S_i and S_j for i, j equal to 1 to k . So, if i is not equal to j then this will be covariance and λ_{ii} is variance of S_i for i is equal to 1 to k . And let λ be the matrix of λ_{ij} for i, j equal to 1 to k . Let us denote by λ^{rs} denote the rs th term of the matrix λ inverse.

Then and also we can write here let us write η_i vector to be covariance of $T S_i$ that is equal to $d g / d \theta_i$ by $d \theta_i$. Now what is T here? T is an unbiased estimator of $g(\theta)$. So, let us look at the problem here once again. We have a probability mass function or probability density function $f(x; \theta)$ we have a random sample X_1, X_2, \dots, X_n here. The parameter space ω is on it has an open interval on the real line. We define the derivatives of the joint density divided by the density as S_i .

And then we have certain conditions because for the existence of this we should have the derivatives existing. Then we should also have and this should be true for i is equal to 1 to k then this integral we should be able to differentiate under the integral sign. Then the terms S_1, S_2, \dots, S_k should be linearly independent. And for any integrable function $\delta(x)$ we should be able to once again differentiate this integral $\delta(x)$ product of $f(x; \theta) d\mu(x)$.

Further we define certain quantities; let us call this λ to be the variance covariance matrix of S_1, S_2, \dots, S_k and we consider λ inverse. And the terms of λ inverse we denote by λ_{rs} . I am defining some additional things let T be an unbiased estimator of $g(\theta)$. So, I am considering in general estimation problem for any parametric function say $g(\theta)$. So, T is an unbiased estimator let us consider the derivative of expectation $T X$.

So, if I consider the i th derivative it will give me expectation of $T S_i$. Since expectation of S_i is 0 this becomes covariance and i denoted by η_i for i is equal to 1 to k . And let us denote η vector to be $\eta_1 \eta_2 \dots \eta_k$. Then Bhattacharyya's bound is that variance of θ variance T is greater than or equal to $\eta' \lambda^{-1} \eta$; which is nothing, but $\lambda_{rs} d g / d \theta_r d r d g / d \theta_s$.

You can see that if I had considered k equal to 1 then this will reduce to the FRC lower bound for k equal to 1. This will reduce to FRC lower bound. Let us look at the proof of this. So, expectation of $T X$ is equal to $g(\theta)$ which we can write as $\int T(x) f(x; \theta) d\mu(x)$ the joint distribution of X_1, X_2, \dots, X_n $d\mu(x)$ is equal to $g(\theta)$. So, this is the statements are true for all θ . Now, this relationship we differentiate let me call it 1.

(Refer Slide Time: 20:53)

Differentiating (1) with respect to θ_i , i times

$$\int \dots \int T(x) \left\{ \frac{\partial^i}{\partial \theta^i} \prod_{j=1}^n f(x_j, \theta) \right\} d\mu(x) = \frac{d^i g}{d\theta^i}$$

or $\int \dots \int T(x) S_i \left\{ \prod_{j=1}^n f(x_j, \theta) \right\} d\mu(x) = \frac{d^i g}{d\theta^i}$

or $E(T S_i) = \frac{d^i g}{d\theta^i}$. Now $E(S_i) = 0, i=1, \dots, k$.

or $\text{Cov}(T, S_i) = \frac{d^i g}{d\theta^i}$. $\Lambda = \text{Dispersion matrix of } S = (S_1, \dots, S_k) = (S_1, \dots, S_k)$

Multiple correlation coefficient between T and (S_1, \dots, S_k)

is $R^2 = \frac{\eta' \Lambda^{-1} \eta}{\text{Var}(T)} \leq 1$

So $\eta' \Lambda^{-1} \eta \leq \text{Var}(T)$. which is the required lower bound.

Differentiating 1 with respect to theta i times. So, i will get integral T x del i by del theta i product f of x j theta j is equal to 1 to n d mu x is equal to on the right hand side we had g so d i g by d theta i. Now this term we can consider as T X del i by del theta in this I divided by the I divided by product of f x j theta.

If I divided by this term this becomes nothing, but S i. And then I can express it as S i into product f x j theta j is equal to 1 to n d mu x is equal to d i g by d theta i. This is nothing, but expectation of T into S i. Now since we are assuming that the density can be differentiated under the integral sign. Therefore, if we differentiate this relationship this is equal to 1. So, if i differentiate this i will get expectation of S 1 is equal to 0. Similarly if I differentiate it twice and again divided by that I will get expectation of S 2 is equal to 0.

So, what we are getting now expectation of S i is 0 for i is equal to 1 to k. So, this relation is an equivalent to covariance between T and S i is equal to dig by d theta i. So, now, let us consider the multiple correlation coefficient between T and S 1, S 2, S k. That is equal to let me use a notation say capital R square that is equal to eta prime lambda inverse eta divided by variance of T.

Because lambda was the dispersion matrix of S that is S is equal to S 1, S 2, S k. So, if I apply the formula for the multiple correlation coefficient I get eta prime inverse lambda inverse eta divided by variance of T. Now this is less than or equal to 1 because multiple

correlation coefficient lies between 0 and 1. Now let me write R not R^2 so I get η prime λ inverse η less than or equal to variance of T .

Now this is nothing, but the Bhattacharyya's bound variance θ T is greater than or equal to let me call it a star. And if I expand these terms then I get this. So, you notice here that in the fresher Rao Cramer lower bound we have used that the correlation is less than or equal to 1. And here we are using in fact, correlation is square is less than or equal to 1. Here we are using multiple correlation is square is less than or equal to 1.
