**Lower Bounds For Variance – VIII**

Now, we move to another generalization of the Rao Cramer Lower Bound; that is the case of several parameters. The lower bound that I have discussed so far here we are resuming or we are calculating the derivatives with respect to 1 parameter that is theta in the problem. And of course, we may consider a function of theta for the estimation problem, but my density function itself may be a function of say a k dimensional parameter say theta 1 theta 2 theta k. Now, we consider this generalization here.

(Refer Slide Time: 01:01)

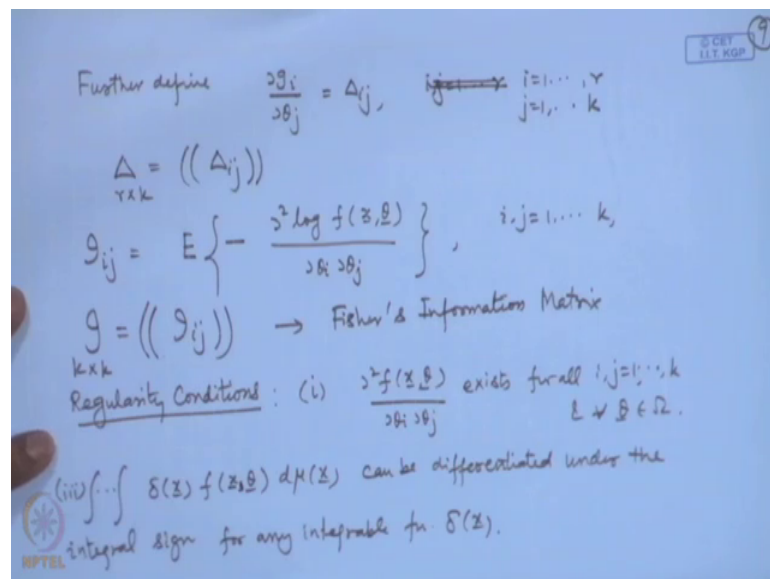

So, Rao Cramer, let me put Frechet Rao Cramer lower bound, now it is not necessary just the lower bound actually we will call it in equality in higher dimensions. So, let us consider say  $X_1, X_2, \dots, X_n$  be a random sample from a population with now, once again we may have a density or mass function  $f(x, \theta)$ .

Now, in the case of one dimension, we have assumed that theta lies in an open interval and the real line. If we are considering k dimensional parameter here, theta is equal to theta 1 theta 2 theta k belonging to omega, then this is a subset of k dimensional Euclidean space, but we have to make another assumption that we may consider an open

interval in  $r$  case. So, what is the meaning of open interval? It can be a ball or an open disk. So,  $\omega$  is an open interval in  $k$  dimensional Euclidean space and we are considering parametric functions say  $g_1, g_2, \dots, g_r$  etcetera. We consider estimation of parametric functions say  $g_1(\theta), g_2(\theta), \dots, g_r(\theta)$ .

Now, let us consider say  $T_1, T_2, \dots, T_r$  be unbiased estimators of  $g_1, g_2, \dots, g_r$  respectively; that is  $E(T_i) = g_i(\theta)$ . What do we do? We define a variance-covariance matrix for  $T_1, T_2, \dots, T_r$ . Let us call  $T$  as  $T_1, T_2, \dots, T_r$  vector. Let us define variance of  $T_i$  as  $V_{ii}$ ; that is variance for  $i = 1$  to  $r$ . We also define covariance between say  $T_i$  and  $T_j$  as  $V_{ij}$  for  $i = 1$  to  $r, j = 1$  to  $r, i \neq j$ . So,  $V$  is the dispersion matrix of  $T$ ; that is the terms of  $V$  are  $V_{11}, V_{12}, \dots, V_{1r}, V_{21}, V_{22}, \dots, V_{2r}$  and so on;  $V_{r1}, V_{r2}, \dots, V_{rr}$ . Let us make certain regularity assumptions here, also we give some notation here.

(Refer Slide Time: 05:26)

We define, say further define  $\Delta_{ij}$  as the terms  $\Delta_{ij}$  for  $i$  and  $j$  equal to  $1$  to  $r$ . Now, you see here, we are considering  $\theta$  to be  $k$  dimensional and  $g_1, g_2, \dots, g_r$  parametric functions are there. So, when I right del  $g_i$  by del  $\theta_j$ , this  $i$  will be from  $1$  to  $r$  and  $j$  will be from  $1$  to  $k$ ; that means, I am considering all partial derivatives of  $g_i$  functions with respect to each of  $\theta_1, \theta_2, \dots, \theta_k$ . And,  $\Delta$  is the matrix of  $\Delta_{ij}$ ; that means, it is an  $r$  by  $k$  matrix ok.

Let us also define a term  $I_{ij}$ , that is equal to expectation of minus  $\frac{\partial^2}{\partial \theta_i \partial \theta_j} \log f(x|\theta)$ . Once again these are for all  $i, j = 1$  to  $k$  and when  $i$  is equal to  $j$ , this will become second order derivative with respect to  $\theta_i$ , in other cases it is iterated second order partial derivative, once with respect to  $\theta_i$  and another time respect to  $\theta_j$ .

Once again we are making certain regularity assumptions like second order differentiability like in the Fisher or Cramer lower bound for one dimensional parameter. In that case the order will not make a difference, whether we write  $\frac{\partial \theta_i}{\partial \theta_j}$  or  $\frac{\partial \theta_j}{\partial \theta_i}$ , both will be same under the regularity conditions.  $I$  is the matrix of  $I_{ij}$ , so this is a  $k$  by  $k$  matrix, this is called Fisher's information matrix. Notice in the case of one dimension, we have written  $E$  to the power expectation of minus  $\frac{\partial^2}{\partial \theta^2} \log f(x|\theta)$  by  $E$  of  $\left(\frac{\partial}{\partial \theta} \log f(x|\theta)\right)^2$  whole square both the quantities were same and I would define it as the Fisher's information  $I$ .

So, now when we have a multi-dimensional parameter, we are defining Fisher's information matrix  $I$ . Then let us make the regularity assumptions, regularity conditions as in the case of one dimensional. We have already made the assumption that the parameter space is an open interval in  $k$  dimensional Euclidean space. Then we have to make the assumption about the existence of the partial derivatives. So,  $\frac{\partial^2 f}{\partial \theta_i \partial \theta_j}$  exists for all  $i, j$  equal to  $1$  to  $k$  and for all  $\theta$ .

We have to also make the assumption about the differentiability under the integral sign that is  $\frac{\partial}{\partial \theta} \int \delta(x|\theta) f(x|\theta) dx$ . So, let me write the joint density was  $f(x|\theta)$ ,  $d\mu(x)$  can be differentiated So, this is an  $n$  fold integral, this can be differentiated under the integral sign for any integrable function  $\delta$ .

(Refer Slide Time: 10:22)

$$g_{ij} = E \left\{ - \frac{\partial^2 \log f(z, \theta)}{\partial \theta_i \partial \theta_j} \right\}, \quad i, j = 1, \dots, k,$$

$$g = \left( (g_{ij}) \right)_{k \times k} \rightarrow \text{Fisher's Information Matrix}$$

Regularity Conditions : (i)  $\frac{\partial^2 f(z, \theta)}{\partial \theta_i \partial \theta_j}$  exists for all  $i, j = 1, \dots, k$  and  $\theta \in \Omega$ .

(iii)  $\int \delta(z) f(z, \theta) d\mu(z)$  can be differentiated under the integral sign for any integrable fn  $\delta(z)$ .

(iv)  $-E \left( \frac{\partial^2 \log f(z, \theta)}{\partial \theta_i^2} \right) > 0$  for every  $\theta \in \Omega$

We also assume that expectation of  $\frac{\partial^2 \log f(z, \theta)}{\partial \theta_i^2}$ , this is positive for every  $\theta$  belonging to  $\Omega$ . Basically the purpose is to have this Fisher's information matrix as an invertible matrix.

(Refer Slide Time: 10:53)

Under the above regularity conditions  $V = \Delta \Sigma^{-1} \Delta'$  is non-negative definite matrix. In particular, we have

$$V_{ii} \geq \sum \sum g^{st} \frac{\partial g_i}{\partial \theta_s} \cdot \frac{\partial g_i}{\partial \theta_t}, \quad g^st \text{ are the terms in } \Sigma^{-1}$$

Proof :  $E_{\theta} T_i = g_i(\theta) \quad \forall \theta \in \Omega \rightarrow \int T_i(z) f(z, \theta) d\mu(z) = g_i(\theta)$

Differentiating the above relation with respect to  $\theta_j$   $\int T_i(z) \frac{\partial f(z, \theta)}{\partial \theta_j} d\mu(z) = \frac{\partial g_i}{\partial \theta_j} = \Delta_{ij} \rightarrow E \left( T_i \cdot \frac{\partial \log f}{\partial \theta_j} \right) = \Delta_{ij} \rightarrow E \left( \frac{\partial \log f}{\partial \theta_j} \right) = 0$

Consider the dispersion matrix of  $T_1, \dots, T_r$   $\frac{1}{f} \frac{\partial f}{\partial \theta_1}, \dots, \frac{1}{f} \frac{\partial f}{\partial \theta_r}$

$$V(T_i) = V_{ij}, \quad i, j = 1, \dots, r$$

$$V \left( \frac{1}{f} \frac{\partial f}{\partial \theta_1} \right) = E \left( \frac{\partial \log f}{\partial \theta_1} \right)^2 = -E \left( \frac{\partial^2 \log f}{\partial \theta_1^2} \right) = g_{11}$$

Under these regularity conditions, under the above regularity conditions, variance of  $T_i$  in fact, we can write  $V = \Delta \Sigma^{-1} \Delta'$  is non-negative definite matrix. In the case of one dimension, we had the term to be non-negative. Here we are saying it

is because here we are dealing with the matrix notation, this becomes a non negative definite matrix.

However for a non-negative definite matrix, we know that the diagonal elements are also non negative. Now the diagonal elements of this will be of what form? In particular if I write only for the diagonal elements we can write that variance of  $T_i$  that is for estimation of  $g_i(\theta)$ , this is greater than or equal to double summation  $\sum_{i=1}^m \sum_{n=1}^n \frac{\partial g_i}{\partial \theta_m} \frac{\partial g_i}{\partial \theta_n} \frac{1}{\sum_{s=1}^m \sum_{t=1}^n \frac{\partial g_i}{\partial \theta_s} \frac{\partial g_i}{\partial \theta_t}}$ , where this  $\frac{1}{\sum_{s=1}^m \sum_{t=1}^n \frac{\partial g_i}{\partial \theta_s} \frac{\partial g_i}{\partial \theta_t}}$  are the terms in  $I$  inverse matrix.

So, this Fisher's information matrix  $I$  which I have taken if you take the inverse of that  $\frac{1}{\sum_{s=1}^m \sum_{t=1}^n \frac{\partial g_i}{\partial \theta_s} \frac{\partial g_i}{\partial \theta_t}}$  element of that  $I$  am denoting by  $I_{st}$ . So, this is the lower bound for the variance of unbiased estimator of the  $I$ th function. Let us look at the proof of this. Let us consider expectation of  $T_i$  is equal to  $g_i(\theta)$ . Now, you differentiate this is true for all  $\theta$ , you differentiate this with respect to say  $\theta_j$ . Differentiating the above relation with respect to  $\theta_j$ . So, how do you differentiate actually this relation, you can write as  $T_i \int f(x|\theta) dx = g_i(\theta)$ .

So, if you differentiate this, this term will be differentiated because this term does not involve  $\theta$ . So, we get it is equal to  $T_i \frac{\partial f}{\partial \theta_j} \int dx = \frac{\partial g_i}{\partial \theta_j}$ , that is the term which I defined as  $\Delta_{ij}$ . And we can also consider, so this is  $\Delta_{ij}$ , also consider the variance covariance are the dispersion matrix of  $T_1 T_2 \dots T_r$  and  $\frac{1}{f} \frac{\partial f}{\partial \theta_1}$  and so on  $\frac{1}{f} \frac{\partial f}{\partial \theta_k}$ .

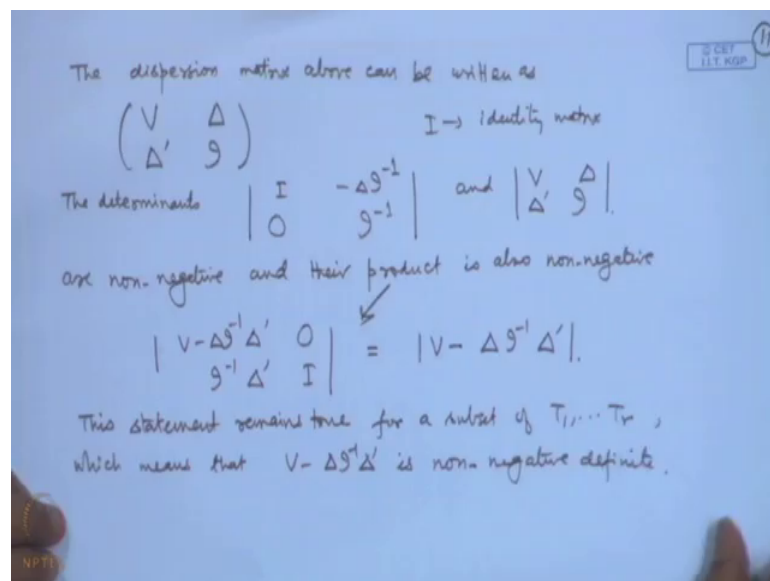

If we consider this  $r+k$  by  $r+k$  dimensional dispersion matrix, what kind of terms will occur here? We will have the variance of  $T_1$ , that is  $V_{11}$ , variance of  $T_2$  that is  $V_{22}$ , variance of  $T_r$  that is  $V_{rr}$ , the variance of  $\frac{1}{f} \frac{\partial f}{\partial \theta_1}$ . Now we have already seen what kind of terms this will be. Actually if we consider this here integral of  $f(x|\theta) dx$ , that is equal to 1 because, this is the density function.

If I differentiate this with respect to any  $\theta$ , I will get 0, that term will give me expectation of  $\frac{\partial f}{\partial \theta_j} \int dx = 0$ . This will be true for all  $j$ 's; that means, variance of  $\frac{1}{f} \frac{\partial f}{\partial \theta_1}$ , it will be equal to expectation of  $\left(\frac{\partial \log f}{\partial \theta_1}\right)^2$  or it is equal to minus of expectation of  $\frac{\partial^2 f}{\partial \theta_1^2}$  square, let me write this..

So, variance of  $T_i$ 's are  $V_{ii}$  for  $i$  is equal to 1 to  $r$ , let us consider say variance of 1 by  $f$   $\frac{\partial f}{\partial \theta_1}$ , that is equal to expectation of  $\frac{\partial \log f}{\partial \theta_1}$  square, that is equal to minus expectation  $\frac{\partial^2 \log f}{\partial \theta_1^2}$ , that is equal to  $i_{11}$ . Why? Because if I define  $I_{ij}$  as expectation of minus  $\frac{\partial^2 \log f}{\partial \theta_i \partial \theta_j}$  here if I take  $i$  is equal to  $j$ , then I get exactly this term. So, this is  $i_{11}$ . So, therefore, variance of 1 by  $f$   $\frac{\partial f}{\partial \theta_k}$  sector that will be  $i_{kk}$ .

Now, there will be correlation, co-variance terms. So, covariance between  $T_1 T_2$  that is  $V_{12}$  and so on. So, this term will be coming. Now, what other type of terms will come? We will get the covariance between  $T_1$  and 1 by  $f$   $\frac{\partial f}{\partial \theta_1}$ . You look at this relation that we have derived here. Here we are getting expectation of  $T_i$  into 1 by  $f$   $\frac{\partial f}{\partial \theta_j}$  into  $f$ . So, this term is reducing to expectation of  $T_i$  into  $\frac{\partial \log f}{\partial \theta_j}$  equal to 0; that is giving that covariance  $T_i$  into  $\frac{\partial \log f}{\partial \theta_j}$  is equal to not 0, it is equal to  $\delta_{ij}$ , equal to  $\delta_{ij}$ . So, the covariance terms between these will give me again  $\delta_{ij}$  terms.

(Refer Slide Time: 18:56)

So, we are getting the, the dispersion matrix above can be written as  $V$   $\Delta$ ,  $\Delta'$   $\mathcal{I}$ . Now, if we consider here, the determinants, here  $\mathcal{I}$  denotes identity matrix So, minus  $\Delta$   $\mathcal{I}^{-1}$  null matrix and  $\mathcal{I}^{-1}$  this is information matrix inverse of that and if we considered say  $V$   $\Delta$ ,  $\Delta'$   $\mathcal{I}$  these are non-negative and their product is also

non-negative. What is the product? Product is this product is  $V - \Delta I^{-1} \Delta'$ ; that is  $V - \Delta I^{-1} \Delta'$ .

Now, this is a dispersion matrix therefore, its determinant must be non negative. Now the same thing will be true if I take any subset of  $T_1 T_2 T_r$  and here also any subset of this. Therefore, for any dimension this determinant will be non negative; that means, this matrix is non-negative definite. This statement remains true for a subset of  $T_1 T_2 T_r$ , which means that  $V - \Delta I^{-1} \Delta'$  is non-negative definite. And, you consider the diagonal elements of this then that would lead to this statement, that is the generalized Rao Cramer inequality for the  $k$  dimensional parameter.

(Refer Slide Time: 21:55)

Example:  $X_1, \dots, X_n \sim N(\mu, \sigma^2)$ , both  $\mu, \sigma^2$  are unknown  
 $\theta = (\mu, \sigma^2)$   
 $g_1(\theta) = \mu, g_2(\theta) = \sigma^2$   
 $\log f(x, \mu, \sigma^2) = -\frac{1}{2} \ln \sigma^2 - \frac{1}{2} \ln 2\pi - \frac{(x-\mu)^2}{2\sigma^2}$   
 $\frac{\partial \log f}{\partial \mu} = \frac{x-\mu}{\sigma^2}, \quad \frac{\partial^2 \log f}{\partial \mu^2} = -\frac{1}{\sigma^2}, \quad g_{11} = \frac{1}{\sigma^2}$   
 $\frac{\partial \log f}{\partial \sigma^2} = -\frac{1}{2\sigma^2} + \frac{(x-\mu)^2}{2\sigma^4}, \quad \frac{\partial^2 \log f}{\partial \mu \partial \sigma^2} = -\frac{(x-\mu)}{\sigma^4}, \quad g_{12} = 0$   
 $\frac{\partial^2 \log f}{\partial \sigma^4} = \frac{1}{\sigma^4} - \frac{(x-\mu)^2}{\sigma^6}, \quad g_{22} = \frac{1}{2\sigma^4}$   
 $g = \begin{pmatrix} 1/\sigma^2 & 0 \\ 0 & 1/2\sigma^4 \end{pmatrix}, \quad g^{-1} = \begin{pmatrix} \sigma^2 & 0 \\ 0 & 2\sigma^4 \end{pmatrix}$

Let me end this lecture by an example. Let us consider say normal  $\mu$  sigma square. So, we have a sample  $x_1, x_2, \dots, x_n$  from normal  $\mu$  sigma square distribution here both  $\mu$  and sigma square are unknown; that means,  $\theta$  is equal to  $\mu$  sigma square here. So, the problem is to find out the Rao Cramer inequality for the unbiased estimator of  $\mu$  and sigma square. So, I am considering  $g_1$  as  $\mu$  and  $g_2$  as sigma square.

So, we consider here the density function  $\log$  of  $f$  will be equal to  $-\frac{1}{2} \ln \sigma^2 - \frac{1}{2} \ln 2\pi - \frac{(x-\mu)^2}{2\sigma^2}$ . If we consider  $\frac{\partial \log f}{\partial \mu}$ , that is  $\frac{x-\mu}{\sigma^2}$   $\frac{\partial^2 \log f}{\partial \mu^2}$  is  $-\frac{1}{\sigma^2}$  that will equal to  $-\frac{1}{\sigma^2}$ .

So,  $I_{11}$  terms is simply minus of this expectation that is  $1$  by  $\sigma^2$ . Similarly if I considered  $\frac{\partial \log f}{\partial \sigma^2}$  I get it as  $-\frac{1}{2\sigma^2} + \frac{(x-\mu)^2}{2\sigma^4}$  plus  $x$  minus  $\mu$  square by  $2\sigma^2$  to the power  $4$   $\frac{\partial^2 \log f}{\partial \mu \partial \sigma^2}$  that will be equal to  $-\frac{x-\mu}{\sigma^4}$ , if I take expectation of this it will become  $0$ , so  $I_{12}$  is  $0$ .

Similarly  $\frac{\partial^2 \log f}{\partial \sigma^2 \partial \sigma^2}$  that will be equal to  $-\frac{1}{2\sigma^4} + \frac{(x-\mu)^2}{\sigma^6}$ . So, that gives us  $I_{22}$  is equal to  $\frac{1}{2\sigma^4}$  minus  $x$  minus  $\mu$  square by  $\sigma^6$ . So,  $i$  matrix simply becomes  $n$  by  $\sigma^2$   $0$   $0$   $n$  by  $2\sigma^4$  to the power  $4$ . So,  $i$  inverse is equal to  $2\sigma^2$ ,  $\sigma^2$  square by  $n$   $2\sigma^2$  to the power  $4$  by  $n$   $0$   $0$ .

So, half diagonal here is  $0$ . So, variance of an unbiased estimator of  $\mu$  will be greater than or equal to  $\sigma^2$  by  $n$ , the variance of an unbiased estimator of  $\sigma^2$  will be greater than or equal to  $2\sigma^4$  by  $n$ .

(Refer Slide Time: 24:48)

Handwritten mathematical derivations on a whiteboard:

$$\frac{\partial \log f}{\partial \mu} = -\frac{1}{\sigma^2} + \frac{(x-\mu)^2}{2\sigma^4}, \quad \frac{\partial^2 \log f}{\partial \mu^2} = -\frac{2(x-\mu)}{\sigma^4}, \quad g_{12} = 0$$

$$\frac{\partial \log f}{\partial \sigma^2} = \frac{1}{2\sigma^4} - \frac{(x-\mu)^2}{\sigma^6}, \quad g_{22} = \frac{1}{2\sigma^4}$$

$$g = \begin{pmatrix} n/\sigma^2 & 0 \\ 0 & n/2\sigma^4 \end{pmatrix}, \quad g^{-1} = \begin{pmatrix} \sigma^2/n & 0 \\ 0 & 2\sigma^4/n \end{pmatrix}$$

$V(T_1) \geq \sigma^2/n$  if  $E(T_1) = \mu$ ,  
 $V(T_2) \geq 2\sigma^4/n$ ,  $E(T_2) = \sigma^2$ .

So, variance of  $T_1$  will be greater than equal to  $\sigma^2$  by  $n$  if expectation of  $T_1$  is  $\mu$  and variance of  $T_2$  will be greater than or equal to  $2\sigma^4$  by  $n$ , if you expectation of  $T_2$  is equal to  $\sigma^2$ . We can also develop this Rao Cramer inequality in the higher dimension for various practical examples like a bivariate normal distribution, where we have 5 parameters,  $m_1$   $\mu_2$  row  $\sigma_1^2$   $\sigma_2^2$  etcetera.

So, we have considered in detail one method for finding out the minimum variance and unbiased estimator. And, this method is not only useful for finding out the minimum variance unbiased estimator; it is also used in other applications of decision theory; such as proving admissibility or minimaxity of an estimator also. In the next lectures we will take up another concept; that is sufficiency.
