**Sufficiency – II**

That we notice when we are proving that  $T$  is equal to  $\sum x_i$  sufficient in the 2 examples that I have consider is that, we are already guessing what is a sufficient statistics. Now in many given problems it may not be obvious that what is sufficient and therefore, this definition of taking conditional distribution to prove that a given statistic is sufficient maybe to combustion. And, moreover it may give rise to like we consider conditional distribution of  $x_1 \times x_2 \times \dots \times x_n$  given say  $x_1 - x_2 + x_3 - x_4$  and so on.

It may turn out that this is not free, we may take  $\sum x_i^2$ , it may not be free from  $\theta$ . Then how to get or you can say, how to get guess an sufficient statistic. Fortunately for this there is a important result called factorization theorem, which readily produces the sufficient statistics.

(Refer Slide Time: 01:27)

So, this is known as Neyman Fisher factorization theorem, named after RA Fisher and Jerzy Neyman, who proved in around 1939. We are not going to give a very very rigorous statement and proof of this theorem, which will be applicable to all situations,

rather we will consider a discrete case here and to write the proof here, for general rigorous statement and proof see the book of say Lehmann and Romano. We are considering a discrete case here, let  $X$  be a discrete random variable, with probability mass function say  $f(x, \theta)$  where  $\theta$  belonging to discrete  $\Theta$ , then  $T(X)$  is sufficient if and only if,  $f(x, \theta)$  is equal to  $g(T(x), \theta) h(x)$  for all  $\theta$ . So, we are calling this as the factorization theorem.

What I am saying is the distribution can be written as product of 2 terms,  $g$  and  $h$ , where  $h$  is a term where parameter does not appear. In the term  $g$ , the parameters  $\theta$  appears but appearance of  $x$  is through  $T$  alone. So, if that is happening then we say  $T$  is sufficient. So, the factorization means that the part of the distribution where the parameter is involved should involve only the sufficient statistics in the form of variables and the other term should be free from the parameter.

Let us look at a proof of this. So, we are considered the discrete case here. So, let us assume say  $f(x, \theta)$  is equal to  $g(T(x), \theta) h(x)$ . Now, let us consider say probability that  $T(x)$  is equal to  $t$ ; that is equal to now, this is a probability which is involving a function of the random variable  $x$ . So, this can be considered as the sum over the probability mass function, over those values of  $x$  for which  $T(x)$  is equal to  $t$ . If I am assuming this factorization I can write it as  $g(T(x), \theta) h(x)$ ,  $x$  such that  $T(x)$  is equal to  $t$ .

Now in the term  $h(x)$  this  $T(x)$  is equal to  $t$  condition is not it is coming whereas, here  $T(x)$  is equal to  $t$  will be true for all the values. So, this term can be taken out of the summation sign, this can be written as  $g(t, \theta) \sum_{x: T(x)=t} h(x)$ . So, if I consider probability of  $X$  is equal to say  $x'$  given  $T(X)$  is equal to  $t$ ; that means, conditional distribution of  $X$  given  $T$ , this is equal to 0, if  $T(x')$  is not equal to  $t$ . And, in other case it is equal to probability of  $X$  is equal to  $x'$  given  $T(X)$  is equal to  $T(x')$  divided by probability of  $T(X)$  is equal to  $t$  which is actually equal to  $T(x')$  here, because I am taking  $T(x')$  is equal to  $t$ .

So, if you consider this now, probability  $X$  is equal to  $x'$  given  $T(X)$  is equal to  $T(x')$  it is same as probability  $X$  is equal to  $x'$ . So, this becomes equal to, let me consider only this star portion; let me call this is a star here I will consider this portion.

(Refer Slide Time: 06:15)

$$P_{\theta}(X=x') = \frac{g(t, \theta) h(x', \theta)}{\sum_{x: T(x)=t} g(t, \theta) h(x, \theta)}$$

which is independent of  $\theta$ . So the conditional distribution of  $X$  given  $T$  is independent of the parameter. So  $T$  is sufficient statistic.

Conversely, let  $T$  is sufficient for  $\theta$ .

$$\Rightarrow P_{\theta}(X=x' | T(X)=t) = c(x', t) \text{ (independent of } \theta \text{)}$$

$$\Rightarrow \frac{P_{\theta}(X=x', T(X)=T(x'))}{P(T(X)=T(x'))} = c(x', t) \text{ (if } T(x)=t \text{)}$$

$$\Rightarrow P_{\theta}(X=x') = c(x', t) P_{\theta}(T(X)=T(x')) = c(x', t) g(t, \theta) h(x', \theta) = h(x', \theta) g(t, \theta)$$

So, this is star portion is equal to  $P_{\theta}(X=x')$  is equal to  $g(t, \theta) h(x', \theta)$  divided by  $\sum_{x: T(x)=t} g(t, \theta) h(x, \theta)$ ; such that,  $T(x)$  is equal to  $t$ ; that is equal to  $g(t, \theta) h(x', \theta)$  divided by  $\sum_{x: T(x)=t} g(t, \theta) h(x, \theta)$ , such that  $T(x)$  is equal to  $t$ . Now this term cancel out. So, you look at this conditional distribution of  $X$  given  $T$ . Now this term is free from the parameter, independent of  $\theta$ .

So, the conditional distribution of  $X$  given  $t$  is independent of the parameter. So,  $T$  is sufficient by the definition of the sufficiency. Let us take the converse part of this theorem. Let us assume that  $T$  is sufficient for  $\theta$ . If we assume that  $t$  is sufficient of  $\theta$ ; that means, I am saying the conditional distribution of  $X$  given  $T(X)$  is a function of only  $x$  prime and  $t$  that is independent of  $\theta$ .

But this left hand side you can write as  $P_{\theta}(X=x' | T(X)=T(x'))$  is equal to  $P_{\theta}(X=x' | T(X)=t)$  divided by  $P(T(X)=T(x'))$ , that is equal to  $c(x', t)$ , if  $T(x)$  is equal to  $t$ . In other case of force, it is equal to 0, so we do not write that that case here. This means that probability of  $X$  equal to  $x$  prime is equal to  $c(x', t)$  and this term. Now what is this term? This term will be simply  $c(x', t) g(t, \theta) h(x', \theta)$  because I am taking  $T(x)$  is equal to  $t$ .

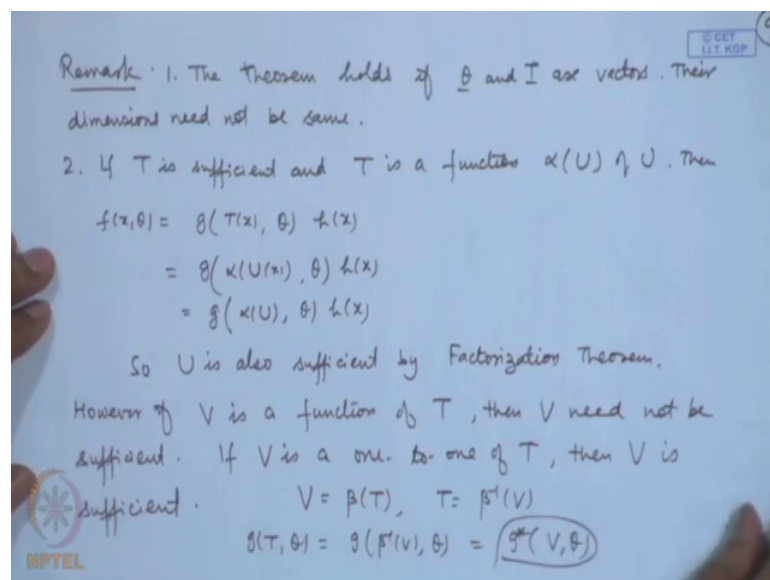

Now this is nothing, but the factorization because this term I can write as  $h(x', \theta) g(t, \theta)$ . So, I have considered this discrete case here because it is easy to write this conditional probability. If the distribution are continues then probability of  $T(X)$  is equal to  $t$  does not

make sense because that will be 0. So, we use the conditional density function form. So, the general proof which is given in the Lehmann and Romano, this takes care of all these cases.

Another point which I would like to mention here, here I have taken theta to be a scalar, but suppose theta is a vector here then what will be the change here? If we make this assumption this theta will become vector, this theta will become vector here. Here also will become a vector, this will become a vector, this will become a vector. So, there is no change in the argument here that means, if the expectation holds t will be sufficient.

Let us look at the converse part. In the converse part, you are saying that this is free from theta, so that I will become vector here and it will not make any difference and here we will write it as a function of t and theta where theta is a vector parameter. So, this result holds even if theta is a vector parameter and another thing is about T also. I am writing here T as a one dimensional term, but that is also not must here T also can have several components like it could be T 1, T 2, T k, similarly theta can be theta 1, theta 2, theta n. So, let me write this as a remark here.

(Refer Slide Time: 10:59)

The theorem holds if theta and T are vectors and another point is that their dimensions need not be the same, their dimensions need not be same. Now let us revisit our statement. I said that if T is a function of U, then U is also sufficient. Now in the factorization theorem, if I substitute t as function of U, then I will be writing it is

something like  $h$  of  $U$ . If I put that thing then it will mean that  $U$  is also sufficient by the same argument.

So, let me add that here. If  $T$  is sufficient and  $T$  is a function; say  $U = \alpha(T)$ , then let us look at the density function,  $f(x|\theta) = \int g(T|x, \theta) h(U) dU$ , this we can write as  $g(U|x, \theta) h(U)$ . Now  $T$  is a function of  $U$ . So, this we can write as  $g$  of a function of  $U$ . So, we can just  $U$  we can write. So,  $U$  is also sufficient by factorization theorem; however, if  $V$  is a function of  $T$ , then  $V$  need not be sufficient. If  $V$  is a 1 to 1 function of  $T$ , then  $V$  is sufficient. This proof is again simple, if we say  $V$  is a 1 to 1 function say,  $V = \beta(T)$ , then we can say  $T = \beta^{-1}(V)$ .

In that case  $g(T|x, \theta)$  you can write as  $g(\beta^{-1}(V)|x, \theta)$ ; that means, it is a function of  $v$  and  $\theta$ . So,  $V$  is also sufficient. Now the definition of sufficiency can be used to prove whether a given statistic is sufficient or not sufficient, because even find out the conditional distribution of a given statistics and you can see whether it is free from the parameter or not; however, you should know what statistic you are checking whereas, the factorization theorem yields a sufficient statistic because it is appearing there.

Now if you want to prove that something is not a sufficient statistic, then factorization theorem will not be useful, because to show that it is not represented is more difficult than saying that it is a function. So, both of the that is the original definition as well as the factorization theorem have different uses.

(Refer Slide Time: 15:15)

Examples. 1. Let  $X_1, \dots, X_n \sim N(\mu, \sigma^2)$ ,  $\mu \in \mathbb{R}$ ,  $\sigma^2 > 0$

Case I:  $\sigma^2$  is known (i.e.  $\sigma^2 = 1$ ).

$X_1, \dots, X_n \sim N(\mu, 1)$ .

The joint pdf of  $X_1, \dots, X_n$  is

$$f(\mathbf{x}, \mu) = \prod_{i=1}^n \left\{ \frac{1}{\sqrt{2\pi}} e^{-\frac{1}{2}(x_i - \mu)^2} \right\}$$

$$= \frac{1}{(\sqrt{2\pi})^n} e^{-\frac{1}{2} \sum (x_i - \mu)^2} = \underbrace{\frac{1}{(\sqrt{2\pi})^n}}_{h(\mathbf{x})} e^{-\frac{\sum x_i^2}{2}} e^{-\frac{n\mu^2}{2} + n\mu \bar{x}}$$

So Factorization theorem gives  $\bar{x}$  as a suff. statistic for  $\{N(\mu, 1) : \mu \in \mathbb{R}\}$

Let me give some examples here. So, let  $X_1, X_2, \dots, X_n$  follows a normal distribution with mean  $\mu$  and variance  $\sigma^2$ , I will consider different cases. As I mentioned to you that the sufficiency is a property of the family of distributions, it is not a property of a variable or a property of the parameter. It is a property which is holding for the family. So, here we are saying  $\mu$  belongs to  $\sigma^2$  is positive. Let us take special cases.

Suppose I say  $\sigma^2$  is known, say  $\sigma^2 = 1$ ; that means, I am saying  $X_1, X_2, \dots, X_n$  follows normal  $\mu = 1$  distribution. Now let us write down the joint distribution of, joint distribution of  $X_1, X_2, \dots, X_n$ . So, that is equal to product  $\frac{1}{\sqrt{2\pi}} e^{-\frac{1}{2}(x_i - \mu)^2}$  from  $i=1$  to  $n$ .

So, this if you see  $\frac{1}{\sqrt{2\pi}}$  to the power  $n$ ,  $e^{-\frac{1}{2} \sum (x_i - \mu)^2}$  minus  $\mu$  square. This we can write as  $\frac{1}{\sqrt{2\pi}}$  to the power  $n$ ,  $e^{-\frac{1}{2} \sum x_i^2}$   $e^{-\frac{n\mu^2}{2} + n\mu \bar{x}}$ , because if I take the cross product that is twice  $\mu x_i$  with the minus sign.

So,  $\frac{1}{\sqrt{2\pi}}$  will cancel out, minus minus will become plus. So, we get  $\mu \sum x_i$  that I write as  $n\mu \bar{x}$ . Now if you write this function  $h(\mathbf{x})$  and this part we consider as a function of  $\bar{x}$  and  $\mu$ , then it is exactly in the form of factorization theorem. We have one term which is free from the parameter and other term which is depended up on the parameter, depends on the variable only through  $\bar{x}$ . So, by factorization theorem gives

$\bar{x}$  as a sufficient statistic. Now this family is normal distributions with variances known. So, here the sufficient statistics is  $\bar{x}$  in a rough way we can say  $\bar{x}$  is sufficient for  $\mu$ .

(Refer Slide Time: 18:35)

Case II:  $\mu$  is known (say  $\mu = \mu_0$ ),  $X_1, \dots, X_n \sim N(\mu_0, \sigma^2)$

$$f(\mathbf{z}, \sigma^2) = \prod_{i=1}^n \frac{1}{\sigma\sqrt{2\pi}} e^{-\frac{1}{2\sigma^2}(x_i - \mu_0)^2}$$

$$= \left(\frac{1}{\sigma\sqrt{2\pi}}\right)^n e^{-\frac{\sum (x_i - \mu_0)^2}{2\sigma^2}} \rightarrow \frac{1}{(\sqrt{2\pi})^n \sigma^n} e^{-\frac{\sum x_i^2}{2\sigma^2} + \frac{\mu_0 n \bar{x}}{\sigma^2} - \frac{n\mu_0^2}{2\sigma^2}}$$

$\sum (x_i - \mu_0)^2$  is suff. for  $\{N(\mu_0, \sigma^2) : \sigma^2 > 0\}$

$$\sum (x_i^2 + \mu_0^2 - 2\mu_0 x_i)$$

$$\sum x_i^2 + n\mu_0^2 - 2\mu_0 \sum x_i$$

Case III: Both  $\mu$  &  $\sigma^2$  are unknown.

$$f(\mathbf{z}, \mu, \sigma^2) = \prod_{i=1}^n \frac{1}{\sigma\sqrt{2\pi}} e^{-\frac{1}{2\sigma^2}(x_i - \mu)^2} = \frac{1}{(\sqrt{2\pi})^n \sigma^n} e^{-\frac{\sum x_i^2}{2\sigma^2} - \frac{n\mu^2}{2\sigma^2} + \frac{\mu \sum x_i}{\sigma^2}}$$

Let us take the second case, I take  $\mu$  is known. If  $\mu$  is known say  $\mu$  is equal to  $\mu_0$ . In that case, the distribution of  $X_1, X_2, \dots, X_n$  is normal  $\mu_0, \sigma^2$ . So, the joint distribution of  $X_1, X_2, \dots, X_n$  will become  $\frac{1}{(\sigma\sqrt{2\pi})^n} e^{-\frac{1}{2\sigma^2} \sum (x_i - \mu_0)^2}$ , that is equal to  $\frac{1}{(\sigma\sqrt{2\pi})^n} e^{-\frac{1}{2\sigma^2} (\sum x_i^2 - 2\mu_0 \sum x_i + n\mu_0^2)}$ .

Now this term we write it as  $\frac{1}{(\sigma\sqrt{2\pi})^n} e^{-\frac{\sum x_i^2}{2\sigma^2} + \frac{\mu_0 \sum x_i}{\sigma^2} - \frac{n\mu_0^2}{2\sigma^2}}$ . Here you see I cannot separate out  $x_i$  like in the case of  $\sigma^2$  known case. So, we can say here that  $\sum x_i^2$  this term I write as  $h(\mathbf{x})$  and remaining term I write as  $g(\bar{x}, \sigma^2)$ .

So,  $\sum x_i^2$  is sufficient for the family of normal distributions. Now we may do this factorization in different way also. We may write here  $\frac{1}{(\sqrt{2\pi})^n \sigma^n} e^{-\frac{\sum x_i^2}{2\sigma^2} - \frac{n\mu^2}{2\sigma^2} + \frac{\mu \sum x_i}{\sigma^2}}$ . So, we get  $\frac{1}{(\sqrt{2\pi})^n \sigma^n} e^{-\frac{\sum x_i^2}{2\sigma^2} - \frac{n\mu^2}{2\sigma^2}}$  and  $e^{\frac{\mu \sum x_i}{\sigma^2}}$ .

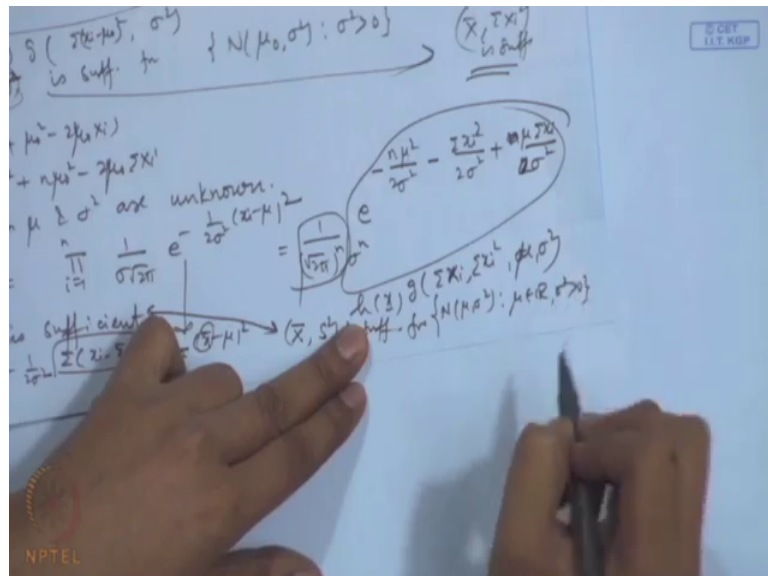

So, this term you can see if it is a function of this term is a function of sigma Xi, sigma xi square and mu and sigma square and this term you can call h x. So, we conclude that sigma Xi, sigma Xi square is sufficient. Here you can see that further reduction is not possible; however, we can consider it in a slightly in a different way as follows. We may write this as e to the power minus 1 by twice square sigma xi minus x bar whole square minus n by 2 sigma square x bar minus mu square; that means, I have added and subtracted x bar term here.

In that case this is actually sigma xi whole square this is x bar. So, we can conclude that X bar and s square, where we have used earlier the notation s square for 1 by n minus 1 sigma Xi minus X bar whole square that is the sample variance, so this is sufficient. Now you see there is no difference in this statement, if I considered x sigma Xi and Xi square then this is 1 to 1 function of X bar S square because, from here I can obtain this and from here I can obtain this.

So, we can say that when the both parameters in a normal distribution are unknown, then the sample mean and the sample variance are sufficient. Now many times we are using it as a misnomer that, expiry sufficient for mu and S square is sufficient for sigma square.

(Refer Slide Time: 25:03)

Actually we have to say this is sufficient for the family normal mu sigma square, mu belonging to r and sigma square greater than 0. I will just explain this discrepancy may occur if we do not maintain this family here.

(Refer Slide Time: 25:19)

Case IV:  $\sigma = \mu$   
 $N(\mu, \mu^2)$   
 $f(z, \mu) = \frac{1}{(\sqrt{2\pi})^n \mu^n} e^{-\frac{n}{2} \left( \frac{\sum x_i^2}{2\mu^2} - \frac{\mu \sum x_i}{\mu} \right)}$   
 $g(\sum x_i, \sum x_i^2, \mu)$   
 So although parameter is one-dimensional,  $(\sum x_i, \sum x_i^2)$  is suff.  
 $(\sum x_i, \sum x_i^2)$  is suff for  $\{N(\mu, \mu^2), \mu > 0\}$ .

For example I take another case say sigma is equal to sigma square is equal to sigma is equal to say sigma is equal to mu, then what happens to the density, it is the distribution is normal mu mu square. If I have this then you can look at this breakup here, that joint density although it is a function of x and mu alone because sigma is vanishes here. This is equal to 1 by root 2 phi to the power n, mu to the power n, e to the power minus n by 2 minus sigma xi square by twice mu square minus mu sigma xi square by mu square that is mu.

So, here you see this is a function of sigma xi, sigma xi square and mu. Although the parameter is one dimensional, the sufficient statistics is two dimensional. So, although parameter is one dimensional, sigma Xi sigma Xi square is sufficient. So, again the statement is again the same, that is sigma Xi sigma Xi square is sufficient for this family normal mu mu square; of course, mu is greater than 0 here.

So, sufficiency is a property of the family of distributions. In the next lecture we will consider few more examples that is how to apply the factorization theorem to derive the various sufficient statistics. And, we will look at the maximal data reduction by means of sufficiency that is the concept of minimal sufficient statistics.

So, in the next lecture will be considering these concepts.
