**Unbiased Test for Normal Populations – II**

So, I have considered testing for the mean of a normal distribution, testing for the variance in a normal distribution. But the crucial difference was that when I was testing for the mean I had considered variance to be known and accordingly the tests which were either UMP for  $h_1$  and  $h_2$  and  $h_3$  and  $h_4$  it was UMP unbiased we were had obtained.

Similarly, for sigma square when I was doing the testing the mu was taken to be known and I had taken without loss of generality to be 0 and once again we had the UMP test for  $h_1$  and  $h_2$  and UMP unbiased test for  $h_3$  and  $h_4$ . Now here both the parameters will be unknown, which is actually more practical, in practice when we discuss certain population it is unlikely that one of the parameters may be known.

(Refer Slide Time: 01:12)

So, the general situation is both the parameters may be unknown. And in this case we will show that when we test for the mean and when we test for the variance we are in general able to derive UMP unbiased tests for all 4 types of hypothesis that is  $h_1$   $h_2$   $h_3$  and  $h_4$ . In particular I will describe in detail the test for  $h_1$  and  $h_4$  because they look

more natural hypothesis,  $H_2$  and  $H_3$  look more artificial hypothesis of course, you can write down the form of the test functions for each of these cases

So, let us firstly, start with applications of Basu's theorem firstly, example of application of Basu's theorem or this corollary in the normal population case.

(Refer Slide Time: 02:13)

The joint density function of  $X_1, \dots, X_n$  is given by:

$$f(\underline{x}, \mu, \sigma^2) = \frac{1}{(\sigma\sqrt{2\pi})^n} e^{-\frac{1}{2\sigma^2} \sum (x_i - \mu)^2}$$

$$= \frac{e^{-\frac{\sum x_i^2}{2\sigma^2} + \frac{n\mu\bar{x}}{\sigma^2}}}{(\sigma\sqrt{2\pi})^n}$$

If we take  $\sigma = \sigma_0$  (fixed), then the density is in one parameter exponential family and  $\bar{X}$  is complete and sufficient.

Let  $U$  to be any statistic which translation invariant (location invariant)

i.e.  $U(x_1 + c, \dots, x_n + c) = U(x_1, \dots, x_n) \quad \forall c \in \mathbb{R}$ .

Then take  $c = -\mu$

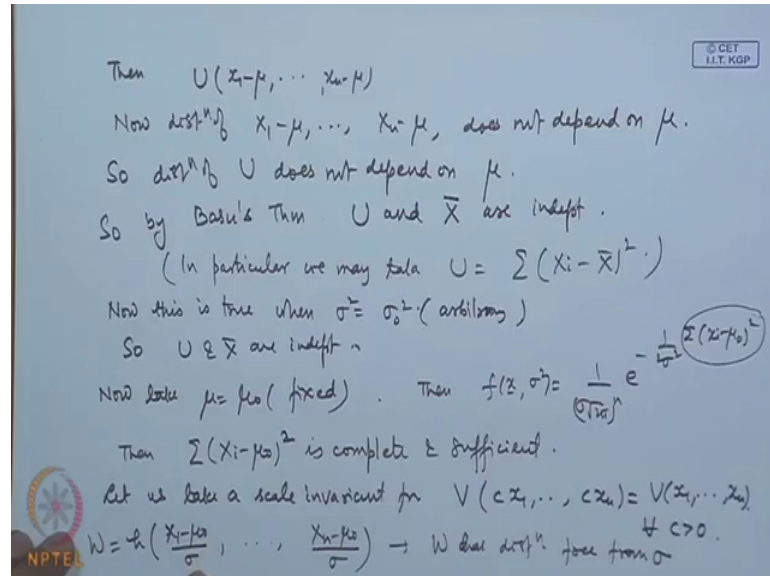

So, let us look at the joint density function of  $X_1, X_2, \dots, X_n$ . So, we are writing it as  $\frac{1}{(\sigma\sqrt{2\pi})^n} e^{-\frac{1}{2\sigma^2} \sum (x_i - \mu)^2}$  that is equal to  $\frac{e^{-\frac{\sum x_i^2}{2\sigma^2} + \frac{n\mu\bar{x}}{\sigma^2}}}{(\sigma\sqrt{2\pi})^n}$  plus  $n\mu\bar{x}$  divided by  $\sigma^2$ .

Note here this is a 2 parameter exponential family, I am looking at the application of Basu's theorem, so firstly we will look at the independence part here. If we take say  $\sigma$  is equal to some fixed value  $\sigma_0$ , if  $\sigma_0$  is fixed here then this term is going into the  $h(x)$  part of a multi parameter exponential family this will become fixed. So, here you have  $\mu\bar{X}$  or  $n\mu\bar{X}$ . So, this is one parameter exponential family then the density is in one parameter exponential family and  $\bar{X}$  is complete and sufficient.

Let us take say  $U$  to be any statistic which is translation invariant or you can say location invariant; location invariant; that means, I am saying  $U(x_1 + c, x_2 + c, \dots, x_n + c)$

that is equal to  $U$  of  $x_1 - \mu, \dots, x_n - \mu$  for all  $c$  on the real line. Now then I can choose  $c$  is equal to say minus of  $\mu$ .

(Refer Slide Time: 05:23)

If I do that then this becomes a function of  $x_1 - \mu$  and so on  $x_n - \mu$ . Now distribution of  $X_1 - \mu, X_2 - \mu, \dots, X_n - \mu$  does not depend on  $\mu$ . So, what we are having  $\bar{X}$  is complete and sufficient the parameter is  $\mu$  here and  $U$  is a function which is having distribution, so distribution of  $U$  does not depend on  $\mu$ .

So by Basu's theorem  $U$  and  $\bar{X}$  are independent, in particular we may take  $U$  is equal to say  $\sum (X_i - \bar{X})^2$ . Of course, in the sampling from normal distributions we know that sample mean and sample variance are independent, but here this is also proved from the Basu's theorem. Now this is true when  $\sigma^2$  is fixed as  $\sigma_0^2$ , but the distribution of  $U$  is arbitrary.

So, if we look at this result here the distribution of  $\sum (X_i - \bar{X})^2$  does not depend upon  $\mu$ . I am sorry this is application of Basu's theorem here  $V$  is ancillary here, so this is following from here. So,  $U$  and  $\bar{X}$  are independent. Now let us take another application here.

Now, take  $\mu$  is equal to  $\mu_0$  another fixing of the mean. Then the density is  $f(x, \sigma^2) = \frac{1}{(\sigma^2)^n} e^{-\frac{1}{2\sigma^2} \sum (x_i - \mu_0)^2}$ . So, this is again one parameter

exponential family and this becomes  $\sum (X_i - \mu_0)^2$  is complete and sufficient.

Let us take a scale invariant function  $V$  that is  $V$  of  $cX_1, cX_2, \dots, cX_n$  is equal to  $V$  of  $X_1, X_2, \dots, X_n$  for all  $c$  positive. Then in particular I can consider  $c$  this to be a function of say  $h$  of  $X_1 - \mu_0$  by  $\sigma$  and so on  $X_n - \mu_0$  by  $\sigma$ , then let me call it say  $W$ , then  $W$  has a distribution free from  $\sigma$  because the distribution of  $X_i - \mu_0$  by  $\sigma$  is normal  $0, 1$ , so this is distribution free from  $\sigma$ .

(Refer Slide Time: 09:35)

Therefore  $\sum (X_i - \mu_0)^2$  &  $W$  are independently distributed.

Suppose  $W = \frac{\bar{X} - \mu_0}{\sqrt{\sum (X_i - \mu_0)^2}}$   $\xrightarrow{X_i \rightarrow cX_i}$   $\frac{c\bar{X} - c\mu_0}{\sqrt{c^2 \sum (X_i - \mu_0)^2}} = W$

Then  $W$  is scale invariant

So  $\frac{\bar{X} - \mu_0}{\sqrt{\sum (X_i - \mu_0)^2}}$  is independent of  $\sum (X_i - \mu_0)^2$ .

2. Let  $X_1, \dots, X_m \sim N(\mu_1, \sigma_1^2)$   
 $Y_1, \dots, Y_n \sim N(\mu_2, \sigma_2^2)$

indep.

NPTEL

And therefore,  $\sum (X_i - \mu_0)^2$  and  $W$  are independently distributed. Suppose I take  $W$  is equal to  $\bar{X} - \mu_0$  divided by  $\sqrt{\sum (X_i - \mu_0)^2}$ . Then  $W$  is a scale invariant because if I change here  $X_i$  to  $cX_i$  then this does not change  $c\bar{X} - c\mu_0$  divided by  $c\sqrt{\sum (X_i - \mu_0)^2}$ . So, this gets cancelled out, so that is equal to  $W$ .

So, this is scale invariant, so  $\bar{X} - \mu_0$  divided by square root of  $\sum (X_i - \mu_0)^2$  is independent of  $\sum (X_i - \mu_0)^2$ . Of course, here  $\mu_0$  is fixed here unlike the previous application where  $\sigma$  was not appearing here  $\mu_0$  was not appearing. So, independence of  $\bar{X}$  and  $\sum (X_i - \bar{X})^2$  was for all  $\sigma$  whereas, this result depends upon the fixed value of  $\mu_0$ .

Let me take another example here let  $X_1, X_2, \dots, X_n$  be a random sample let me take say  $X_1, X_2, \dots, X_n$  be a random sample from normal  $\mu_1, \sigma_1^2$  and  $Y_1, Y_2, \dots, Y_n$  be another random sample from normal  $\mu_2, \sigma_2^2$ . I also assume that these two are independent these two samples are taken independently.

(Refer Slide Time: 12:00)

The joint density of  $X_1, \dots, X_n, Y_1, \dots, Y_n$

$$f(x, y, \mu_1, \mu_2, \sigma_1^2, \sigma_2^2) = \frac{1}{(\sigma_1 \sqrt{2\pi})^n} e^{-\frac{1}{2\sigma_1^2} \sum (x_i - \mu_1)^2} \cdot \frac{1}{(\sigma_2 \sqrt{2\pi})^n} e^{-\frac{1}{2\sigma_2^2} \sum (y_j - \mu_2)^2}$$

$$= \frac{1}{(\sigma_1 \sigma_2 \cdot 2\pi)^n} e^{-\frac{n\mu_1^2}{2\sigma_1^2} - \frac{n\mu_2^2}{2\sigma_2^2}} e^{-\frac{\sum x_i^2}{2\sigma_1^2} - \frac{\sum y_j^2}{2\sigma_2^2} + \frac{n\mu_1 \bar{x}}{\sigma_1^2} + \frac{n\mu_2 \bar{y}}{\sigma_2^2}}$$

This is density in 4-parameter exponential family

$$\theta_1 = -\frac{1}{2\sigma_1^2}, \theta_2 = -\frac{1}{2\sigma_2^2}, \theta_3 = \frac{n\mu_1}{\sigma_1^2}, \theta_4 = \frac{n\mu_2}{\sigma_2^2}$$

$$T_1 = \sum X_i^2, T_2 = \sum Y_j^2, T_3 = \bar{X}, T_4 = \bar{Y}$$

So the parameter space is 4-dim. (convex)  
So  $\underline{T} = (T_1, T_2, T_3, T_4)$  is complete & sufficient.

Then let us write down the joint density of  $X_1, X_2, \dots, X_n$  and  $Y_1, Y_2, \dots, Y_n$ , then that will be  $f(x, y, \mu_1, \mu_2, \sigma_1^2, \sigma_2^2)$  that is equal to  $\frac{1}{(\sigma_1 \sqrt{2\pi})^n (\sigma_2 \sqrt{2\pi})^n} e^{-\frac{1}{2\sigma_1^2} \sum x_i^2 - \frac{1}{2\sigma_2^2} \sum y_j^2 + \frac{n\mu_1 \bar{x}}{\sigma_1^2} + \frac{n\mu_2 \bar{y}}{\sigma_2^2}}$ .

Now, this I will simplify and we can consider this expression is  $\frac{1}{(\sigma_1 \sigma_2 \cdot 2\pi)^n} e^{-\frac{n\mu_1^2}{2\sigma_1^2} - \frac{n\mu_2^2}{2\sigma_2^2} - \frac{\sum x_i^2}{2\sigma_1^2} - \frac{\sum y_j^2}{2\sigma_2^2} + \frac{n\mu_1 \bar{x}}{\sigma_1^2} + \frac{n\mu_2 \bar{y}}{\sigma_2^2}}$ .

So, this is a density in 4 parameter exponential family we may write say  $\theta_1$  is equal to  $-\frac{1}{2\sigma_1^2}$ ,  $\theta_2$  is equal to  $-\frac{1}{2\sigma_2^2}$ ,  $\theta_3$  as say  $\frac{n\mu_1}{\sigma_1^2}$ ,  $\theta_4$  is equal to  $\frac{n\mu_2}{\sigma_2^2}$ . We may write  $T_1$  as  $\sum X_i^2$ ,  $T_2$  as  $\sum Y_j^2$ ,  $T_3$  as  $\bar{X}$ ,  $T_4$  as  $\bar{Y}$ .

So, here the parameter space is natural parameter space, so the parameter space is 4 dimensional; 4 dimensional and also it is convex. So, T is equal to T 1, T 2, T 3, T 4 is complete and sufficient here. Sufficiency follows from the factorization theorem and completeness follows from the theorem which is given in the lemma that if a k parameter exponential family contains a k dimensional rectangle the parameter space of a k dimensional rectangle family then the corresponding statistic which is appearing in the exponent will be complete.

(Refer Slide Time: 15:52)

Now consider  $R = \frac{\sum (X_i - \bar{X})(Y_i - \bar{Y})}{\sqrt{\sum (X_i - \bar{X})^2} \sqrt{\sum (Y_i - \bar{Y})^2}}$

If we make change of location & scale  
 i.e.  $X_i \rightarrow aX_i + b$ ,  $Y_i \rightarrow cY_i + d$ ,  $a > 0, c > 0$   
 then

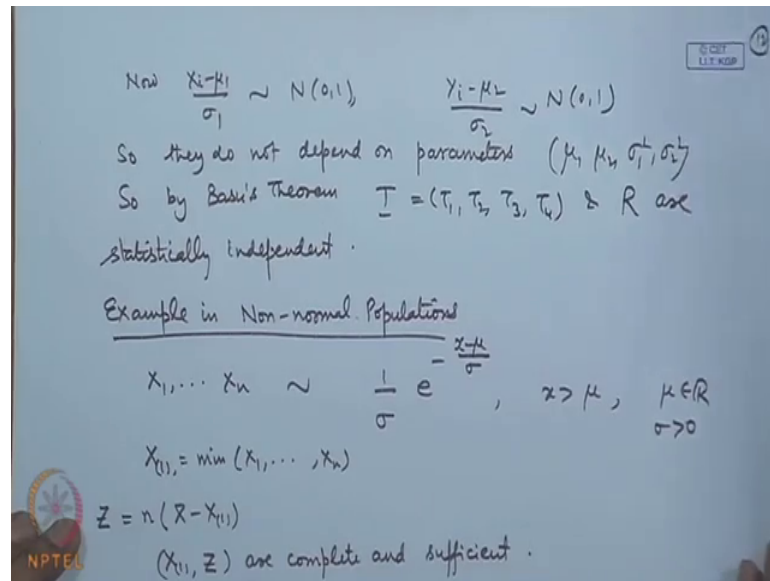

$$\frac{\sum (aX_i + b - a\bar{X} - b)(cY_i + d - c\bar{Y} - d)}{\sqrt{\sum (aX_i + b - a\bar{X} - b)^2} \sqrt{\sum (cY_i + d - c\bar{Y} - d)^2}} = R.$$

So R is invariant under location & scale changes.  
 i.e. R is a fn of  $\frac{X_i - \mu_1}{\sigma_1}$ ,  $\frac{Y_i - \mu_2}{\sigma_2}$ ,  $i = 1, \dots, n$ .

Now, consider say R that is actually the sample correlation coefficient. If we make change of location and scale, that is if I say  $X_i$  goes to say  $aX_i + b$  and  $Y_i$  goes to some  $cY_i + d$ . Then what happens here? If you look at this term  $\sum (aX_i + b - a\bar{X} - b)(cY_i + d - c\bar{Y} - d)$  divided by similarly here  $\sqrt{\sum (aX_i + b - a\bar{X} - b)^2} \sqrt{\sum (cY_i + d - c\bar{Y} - d)^2}$  whole square.

So, now this if you see here  $b$  will cancel  $d$  will cancel  $c$  and they will come out and here also  $a$  and  $c$  will come out. So, we of course, put the condition  $a > 0$  and  $c > 0$  then this is equal to  $R$  again. So,  $R$  is invariant under location and scale changes; that means,  $R$  is a function of  $\frac{X_i - \mu_1}{\sigma_1}$ ,  $\frac{Y_i - \mu_2}{\sigma_2}$  for  $i = 1$  to  $n$ .

(Refer Slide Time: 18:15)

Now, the distributions of  $X_i - \mu_1$  by  $\sigma_1$  that is normal  $0, 1$  distribution of  $Y_i - \mu_2$  by  $\sigma_2$  that is normal  $0, 1$ . So, they do not depend upon parameters  $\mu_1, \mu_2, \sigma_1^2, \sigma_2^2$ . So, what we are having now? We have the parameters appearing  $\theta_1, \theta_2, \theta_3, \theta_4$  which is a 1 to 1 function of  $\mu_1, \mu_2, \sigma_1^2$  and  $\sigma_2^2$ .

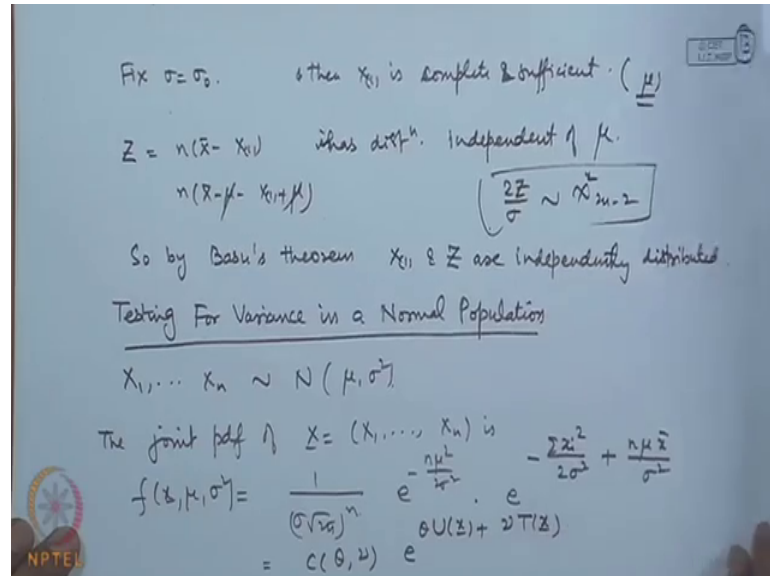

The corresponding complete sufficient statistic is  $T_1, T_2, T_3, T_4$  or which is a 1 to 1 function of  $\bar{X}, \bar{Y}$  and  $\sum X_i^2, \sum Y_j^2$ . Now what we have demonstrated the sample correlation coefficient has a distribution which does not depend upon the parameters. So, by Basu's theorem then  $T$  that is  $T_1, T_2, T_3, T_4$  and  $R$  they are independently distributed.

So, this Basu's theorem is very useful result and I have given applications to the normal distributions, but it has also applications in exponential populations, inverse Gaussian populations there are various distributions where this Basu's theorem is extremely useful. Let me give an example which is different from this normal population's example in say non normal; non normal populations.

Let us take say  $X_1, X_2, \dots, X_n$  following  $\frac{1}{\sigma} e^{-\frac{x-\mu}{\sigma}}$  where  $\mu$  is any real number  $\sigma$  is a positive parameter; that means, I am considering a 2 parameter exponential distribution. Now this is not a exponential family; however, we have earlier shown  $X_{(1)}$  that is the minimum of  $X_1, X_2, \dots, X_n$  and if I

consider say  $n$  times  $\bar{X} - \mu$ . Then let me give some name to this let me call it say  $Z$  then  $\bar{X}$  and  $Z$  they are complete and sufficient.

(Refer Slide Time: 21:46)

Now if I fix a sigma fix sigma is equal to sigma naught then what happens we will get then  $\bar{X}$  is complete and sufficient  $\bar{X}$  is complete and sufficient. Now  $Z$  if I take  $n \bar{X} - n\mu$  this is how. So, now, this is completed and sufficient and the parameter is actually  $\mu$  now here and if I consider say  $n \bar{X} - n\mu - n\bar{X} + n\mu$ , so this gets cancelled out.

So, this is this has a distribution independent of  $\mu$  in fact, we know the distribution  $2Z$  by  $\sigma$  actually follows chi square on 2 and minus 2 degrees of freedom. So, by Basu's theorem you will have that  $\bar{X}$  and  $Z$  are independently distributed. So, I have given an example of a non normal population now let us pay attention to the testing problems, testing for say variance in a normal population

So, if I am writing down the density function of  $X_1, X_2, \dots, X_n$   $f(x, \mu, \sigma^2)$  that is equal to  $1 / (\sigma \sqrt{2\pi})^n e^{-\sum (x_i - \mu)^2 / (2\sigma^2)}$  by  $\sigma^2$  e to the power minus  $\sum (x_i - \mu)^2 / (2\sigma^2)$  plus  $n\mu \bar{x} / \sigma^2$ . So, here I am considering testing for  $\sigma^2$ , so I will consider here this part as say  $c(\theta, x) e^{-\sum (x_i - \mu)^2 / (2\sigma^2)}$ .

(Refer Slide Time: 24:53)

When  $\theta = -\frac{1}{2\sigma^2}$ ,  $U = \sum X_i^2$ ,  $W = \frac{n\mu}{\sigma^2}$ ,  $T = \bar{X}$ .  
 Define  $\theta_0 = -\frac{1}{2\sigma_0^2}$   
 Then  $H_1: \theta \leq \theta_0$  vs  $K_1: \theta > \theta_0$   
 $\Leftrightarrow H_1^*: \sigma^2 \leq \sigma_0^2$  vs  $K_1^*: \sigma^2 > \sigma_0^2$ .  
 $\theta_1 = -\frac{1}{2\sigma_1^2}$ ,  $\theta_2 = -\frac{1}{2\sigma_2^2}$   
 $H_2: \theta \leq \theta_1$  or  $\theta \geq \theta_2$  vs  $K_2: \theta_1 < \theta < \theta_2$   
 $\Leftrightarrow H_2^*: \sigma^2 \leq \sigma_1^2$  or  $\sigma^2 \geq \sigma_2^2$  vs  $K_2^*: \sigma_1^2 < \sigma^2 < \sigma_2^2$ .  
 $H_3 \rightarrow H_3: \theta = \theta_0$  vs  $K_3: \theta \neq \theta_0$   
 $\Leftrightarrow H_4^*: \sigma^2 = \sigma_0^2$  vs  $K_4^*: \sigma^2 \neq \sigma_0^2$ .

So, I have defined here theta is equal to minus 1 by 2 sigma square, U is equal to sigma Xi square nu is equal to say n mu by sigma square and T is equal to X bar. If I consider say testing problem, so now, by the theory that I have developed for that UMP bias test I can say that UMP bias test will exist if I test for theta hypothesis say H 1 versus K 1 H 2 versus K 2 x 3 versus K 3 and x 4 versus K 4.

For all the 4 hypothesis I will have UMP bias test for theta. Now what does testing for theta means? Since theta is equal to minus 1 by 2 sigma square the test is exactly reflected and this is an increasing function of sigma square minus 1 by 2 sigma square. So, if I write down a test like this suppose I define theta naught is equal to minus 1 by 2 sigma naught square then H naught theta less than or equal to theta naught versus K sorry H 1 theta better than theta naught. This testing problem is equivalent to let me call it H 1 star sigma square less than or equal to sigma naught square versus K 1 star the sigma square greater than sigma naught square.

Similarly, if I define say theta 1 is equal to minus 1 by 2 sigma 1 square, theta 2 is equal to minus 1 by 2 sigma 2 square, then if I write down the hypothesis problem theta less than or equal to theta 1 or theta greater than or equal to theta 2 versus K 2 theta 1 less than theta less than theta 2. Then this testing problem is equivalent to H 2 star, sigma square less than or equal to sigma 1 square or sigma square greater than or equal to sigma 2 square versus sigma 1 square less than sigma squared less than sigma 2 square.

And in a similar way if I consider  $H_3$  and similarly  $H_4$  that is  $\theta = \theta_0$  that is equivalent to  $H_4: \theta \sigma^2 = \sigma_0^2$  versus  $K_4: \theta \sigma^2 \neq \sigma_0^2$ . Therefore, we have demonstrated here that the theory of UMP unbiased test for multi parameter exponential families, where we test for one parameter in the multi parameter exponential family other parameters are treated as constants.

Then that theory is applicable for two parameter normal population when we want to test for the variance I have put it exactly in that framework. Now let me write down the test here by using theorem 2 that I gave yesterday, where the test was conditional of  $U$  given  $T$ . Now what is  $U$  given  $T$  here? It will be  $\sum X_i^2$  given  $\bar{X}$ ; that means, the test will be conditional test on  $\sum X_i^2$  given  $\bar{X}$  and I mentioned in the beginning of this lecture that this is slightly complicated problem.

What we need to do is to apply the theorem 3 that I gave today; that means, I define suitably a function. So, either in the condition  $U$  is greater than or equal to  $c$  or  $T$  etcetera. I modify the condition in such a way that the term becomes free from  $T$  and similarly if I apply the theorem 3 which I gave today then I need to suitably define a function of this type.

So, in the following lecture I will be doing this work in the detail that is how to define this function  $W$  is equal to  $H(U, T)$ , I will consider it for a  $H_1$  versus  $K_1$  problem and that will be applicable for  $H_2$  versus  $K_2$ , it will also be applicable to  $H_3$  versus  $K_3$ ; however, there will be a problem if I consider  $H_4$  versus  $K_4$ . So, in  $H_4$  versus  $K_4$  a new function which is a linear function of  $U$  that has to be defined. So, we will demonstrate all of this in the following lecture here.
