

Mathematical Methods For Boundary Value Problem
Prof. Somnath Bhattacharyya
Department of Mathematics
Indian Institute of Technology, Kharagpur

Lecture - 10
Numerical Techniques for IVP; Shooting Method for BVP (Contd.)

So, we will come back. Now we will consider the higher order scheme for the initial value problem and then subsequently we will go to the boundary value problem solutions.

Now there are a method to solve the boundary value problem by converting the boundary value problem to a equivalent initial value problem, that is the thing we will be emphasize today's this lecture. Now, we stopped in the first order Euler equation, Euler scheme.

(Refer Slide Time: 01:06)

$$\frac{dy}{dx} = f(x,y) \quad (1)$$
$$\frac{y_{n+1} - y_n}{\delta x} = f_n + O(h)$$
$$\frac{y_{n+1} - y_n}{\delta x} = f_{n+1} + O(h) \quad X$$

Predictor-Corrector Method:

Integrate between x_n to x_{n+1} $\int f(x,y)$

$$y_{n+1} - y_n = \int_{x_n}^{x_{n+1}} f(x,y) dx.$$

So, this was like dy/dx equal to $f(x,y)$. So, what I did is at $n+1$ this is the scheme what we proposed and this is a order h if I do the analysis that is series Taylor series expansion of y and so, the truncation error is order h and it is consistent and we have shown that it is stable provided δx is that condition we have derived and also we have shown in the previous example, that a implicit scheme is stable.

Now, implicit scheme is unconditionally stable. Now the implicit this is explicit. So, implicit scheme was $y_{n+1} - y_n = \delta x f_{n+1}$. Now this is not a very useful one because the unknown here is y_{n+1} and it is involved in a function form f inside the function f . So, we cannot obtain the y_{n+1} straight away. So, this is that is why it is not a useful scheme though it is a stable one.

Now, one remedy there are several remedies one class of method, this is call the predictor corrector method. So, my intention is not to talk much about the initial value problem. So, I suggest that remaining other methods, one can look into the other literatures. So, the predictor corrector method the basic idea is say one extension or one improvement of the Euler's scheme, we can propose this manner. Say if we integrate the equation say this is one integrate between x_n to x_{n+1} of 1.

So, what I get is $y_{n+1} - y_n = \int_{x_n}^{x_{n+1}} f(x, y) dx$. So, this is a exact representation, we have not make any approximation as it is. So, now, what we do this integration of course, its not a very straight away we can integrate it.

(Refer Slide Time: 03:50)

Integrate between x_n and x_{n+1}

$$y_{n+1} - y_n = \int_{x_n}^{x_{n+1}} f(x, y) dx$$

Trapezoidal rule

$$= \frac{\delta x}{2} [f(x_n, y_n) + f(x_{n+1}, y_{n+1})] + O(h^3)$$

$$y_{n+1} = y_n + \frac{\delta x}{2} [f_n + f(x_{n+1}, y_{n+1})]$$

implicit scheme

Predictor - Corrector Method

Step-I : Predictor, $y_{n+1}^{(P)} = y_n + h f_n$

Step-II : Corrector $y_{n+1}^{(k+1)} = \frac{\delta x}{2} [f_n + f(x_{n+1}, y_{n+1}^{(k)})]$

$y_{n+1}^{(0)} = y_{n+1}^{(P)}$ $k \geq 0$

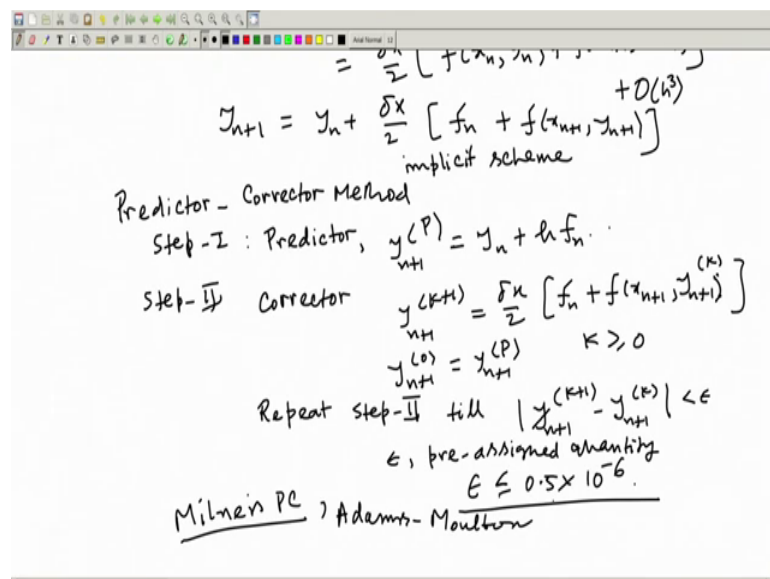

So, what we do we use trapezoidal rule. So, if I use trapezoidal rule for integrating this, what I get is δx by 2 f_{x_n, y_n} plus $f_{x_{n+1}, y_{n+1}}$. So, this is an implicit scheme, but advantage is that it is a very high accuracy order h^3 .

So, we can have a truncation error of order h^2 , that is if we replace that dy/dx by this form. So, the y_{n+1} can be expressed in this manner Δx by 2 now as. So, this is Δx by 2 sometimes it is also written as h . So, $f_n + f_{x_n, y_n}$. Now this cannot be used straight away. So, this is an implicit one. So, what we do a two step procedure is adopted the two step is that a predictor corrector. So, predictor step predictor corrector method which is basically a two step method.

So, in the step I what you do is a predict which is called a predictor step. So, we do a prediction for y_{n+1} , we call as p and that is simple Euler method if we use $y_n + h f_n$. So, this is a first order prediction for the unknown y_{n+1} now we come to the step II and that has to be done in an iterative manner.

So, this is $y_{n+1}^{k+1} = \Delta x [f_n + f_{x_{n+1}, y_{n+1}^{(k)}}]$ and what is $y_{n+1}^{(k)}$ is $y_{n+1}^{(k-1)}$ we call this as iteration, where $k \geq 0$ and $y_{n+1}^{(0)}$ is $y_{n+1}^{(P)}$. And this process repeats step II till we have a.

(Refer Slide Time: 06:43)

So, you need to repeat step II till we get that two successive iterates are very close; that means, $y_{n+1}^{(k)}$ is less than epsilon, epsilon is pre assigned its pre assigned quantity. So, epsilon is a something like 0.5 into 10 to the power minus 6 or so, or even less than that. So, that is depending on the accuracy what we are looking for. So, this is the way the predictor corrector step method goes.

So; that means, from a simple formula we used to predict the solution, a simple formula we use to get a predicted value; that means, this is the first step and then we use this first step to get the correction at every iterative manner. So, once this is achieved we get the solution. So, this is one of the class of predictor correctors method and there are several others I am not going to discuss about that the Milnes predictor corrector method Milnes PC method Adams Moulton methods and so, on. So, these are basically a class of method which is developed while integrating this one.

So, here we have used only the h key trapezoidal formula; that means, trapezoidal formula means what we did is we had taken a linear approximation of f that is using two points. So, if you use the Simpson predicted Simpson formula, so, it will be giving you higher accuracy and so, on that is what Milnes predictor corrector method is. So, I leave this one now. So, this is again a multi-step implicit skip. So, of course, this is a single step. So, far, but this Milnes predictor corrector method or Adams Moulton predictor corrector method. So, they are of multi-step methods.

So, now a predictor corrector method is also we have to write the algorithm twice and all these things. So, there are several one of the most useful method. So, what we need a method which is high accurate self-starting so; that means, it is a single step; that means, by using x_n we can get obtain the solution at x_{n+1} and so, on.

So, if this kind of situation is there then it is a single step and if it is higher order. So, single step higher order is the one which will be most useful for obtaining the solution. So, one of them is luckily one can derive is the one proposed by Runge Kutta. So, that method is I will described now. In the Runge Kutta method what we do. So, like what we did for the Taylor series expansion the same way

(Refer Slide Time: 10:17)

Handwritten mathematical derivation on a whiteboard:

$$z_{n+1} = y_n + h f_n + \frac{h^2}{2} [f_{xx} + f f_{yy}] \Big|_{x_n} + O(h^3) \quad (i)$$

$$y_{n+1} = y_n + \int_{x_n}^{x_{n+1}} f(x, y) dx$$

Integral MVT

$$= y_n + h f(\bar{x}, \bar{y}) \cdot \delta x \quad (ii)$$

$h = \delta x$ $\bar{x} = x_n + \alpha \delta x$, $\bar{y} = y_n + \beta \delta x$.

$\alpha, \beta \rightarrow$ are arbitrary.

$$h f(x_n + \alpha h, y_n + \beta h) = h f_n + h^2 \alpha f_{xx} \Big|_{x_n} + \beta h^2 f_{yy} \Big|_{x_n} + O(h^3)$$

$$y_{n+1} - y_n = h f(\bar{x}, \bar{y})$$

So, what I do is we make an expansion say, y_{n+1} equal to y_n plus $h \, dy/dx$ so, that I can write as f_n plus h square by 2 $d^2 f$. So, it is a x we are writing. So, f_{xx} plus $f f_{yy}$ and that is evaluated at x_n at n that is the better way of representing n plus order h cube, n stands for x_n rather. Now this is one formula up to order h cube.

Now, if I integrate this one, y_{n+1} equal to y_n plus x_n to x_{n+1} $f(x, y) \, dx$. Now this if I apply the integral mean value theorem integral mean value theorem. So, integral mean value theorem means what I do is we have to take a intermediate value and then this will be taken out. So, y_n plus some $f(\bar{x}, \bar{y})$ we denote this way and this is δx , where \bar{x} we can call as x_n plus $\alpha \delta x$ and \bar{y} equal to y_n plus $\beta \delta x$ α β are arbitrary constants.

So, we have two relations like that way let us called this is two. Now if I expand these $f(x_n + \alpha h, y_n + \beta h)$ let us write as δx and $y_n + \beta h$ by Taylor series again. So, what I get is $h f_n$. So, we have here sorry here it will be h will be multiplied because x_n into $x_n + 1$. So, $h f_n$ I can write as h this is the $h f(\bar{x}, \bar{y})$.

So, this term we are expanding by Taylor series. So, this is $h f_n$ plus h into h square α and f_{xx} at x_n plus βh square f_{yy} because this is the one at x_n two variables Taylor series expansion next term will be all order h cube because already h is multiplied this is a second order.

So, this is basically a linear expansion, but since h is multiplied. So, the next term will be of order h cube. So, now, we are keeping all in the order h cube form h cube terms. So, now, $y_{n+1} - y_n$ is our $h f(x_n, y_n)$. So, now, if I substitute this if I compare. So, what I get here is if I compare this two. So, and the other one in the very beginning we have the Taylor series expansion.

(Refer Slide Time: 14:27)

$$h = \delta x \quad \bar{x} = x_n + \alpha \delta x, \quad y = y_n + \beta \delta x$$

$$\alpha, \beta \rightarrow \text{are arbitrary.}$$

$$h f(x_n + \alpha h, y_n + \beta h) = h f_n + h^2 \alpha f_{xx}|_{x_n} + \beta h^2 f_y|_{x_n} + O(h^3)$$

$$y_{n+1} - y_n = h f(\bar{x}, \bar{y})$$

$$h f_n + \frac{h^2}{2} [f_{xx} + f f_{yy}]_{x_n} + O(h^3) = h f_n + \alpha h^2 f_{xx}|_{x_n} + \beta h^2 f_y|_{x_n} + O(h^3)$$

$$\alpha = \frac{1}{2}, \quad \beta = f_n / 2$$

$$y_{n+1} = y_n + h f_n + \frac{h^2}{2} [f_{xx} + f f_{yy}]_{x_n} + O(h^3)$$

$$= y_n + \frac{h}{2} [f_n + (f_n + h f_{xx} + h f f_{yy})]_{x_n} + O(h^3)$$

$$\text{Since, } f(x_n + h, y_n + h f_n) = \underline{f_n + h f_{xx}|_{x_n} + h f f_{yy}|_{x_n} + O(h^2)}$$

So, what I get is $h f_n$ plus h square by 2 f_{xx} plus $f f_{yy}$ at x_n order h cube this is equal to $y_{n+1} - y_n$ and that is equal to this $h f(x_n, y_n)$ and I can write as $h f_n$ plus $\alpha h^2 f_{xx}$ plus $\beta h^2 f_y$ plus order h cube both side this means this is the 1 and this 3.

So, now because this is happening for any choice of h for all values of h whatever the h I choose this is happening. So, if I equate because this is a polynomial. So, if I equate the like powers of h , I compare this like powers of h I can now say that this implies h of n of n get cancelled. So, this implies $f_{xx} \alpha h^2$ equal to $\alpha h^2 f_{xx}$ equal to h^2 square by 2. So, α becomes half and from here what I get is β , I think this is I can just say α equal to half and β becomes βh^2 . So, f_n by 2. So, β equal to f_n by 2.

So, this two coefficients which was arbitrarily arbitrary constants, what was used for integral mean value theorem can be now said as half n f_n by 2. So, now, from the equation, what we have here $y_{n+1} = y_n + h f(x_n, y_n)$. So, this one and also from these h

\bar{y} . Now if I substitute this. So, I get y_{n+1} equal to $y_n + h \bar{f}$ or this one. So, $h f_n + h^2$ by $2 f_x + f_y$ because α and this is at x_n plus order h^3 . So, this is I am getting by from here by putting the value of α and β .

Now, I can write this one as $y_n + h$ by $2 f_n$ if I take common and then f_n plus all these terms $h f_x + h f_y$ at x_n , order h^3 and also if you look into the since if $x_n + \alpha h$ $y_n + \beta h$ which was our \bar{f} . So, $f(x_n + \alpha h, y_n + \beta h)$. So, this is the one.

So, the putting the value of α and β . So, what I know is $f_n + h$ if I take out. So, $h f_x + h f_y$ at x_n of course, this is at x_n . So, f_y basically no this is not α this is this is the one is $h \beta f_y$. Now, $x_n + h$ $y_n + h f_n$. So, this is what is this quantity is.

(Refer Slide Time: 20:18)

Since, $f(x_n + h, y_n + h f_n) = f_n + h f_x + h f_y + O(h^3)$

$$y_{n+1} = y_n + \frac{h}{2} [f_n + f(x_n + h, y_n + h f_n) + O(h^3)]$$

$$k_1 = f(x_n, y_n)$$

$$k_2 = f(x_n + h, y_n + h f_n)$$

$$y_{n+1} = y_n + \frac{h}{2} [k_1 + k_2]$$

Second-order Runge-Kutta Method.
Self-starting, explicit scheme.

So, what I can write now that y_{n+1} can be written as $y_n + h$ by $2 f_n + f(x_n + h, y_n + h f_n)$. So, order h^3 . So, this is what is the second order Runge Kutta method is. The this form now if I evaluate the y_{n+1} by this method. So, this is a self-starting method; that means, you have x_n values is provided and using this x_n value I can or using this y_n value or there is a y at x_n , I can get the solution at $n + 1$.

So; that means, n equal to 0 which is our initial condition that is y_0 . So, that is why it is also referred as the self-starting. Now the for the formula wise what is written as let us call this k_1 equal to if I take out the h outside. So, this is $x_n y_n$ and k_2 is equal to f of x_n plus $h y_n$ plus $h f_n$; then y_{n+1} equal to h by $2 k_1$ plus k_2 which is called the second order Runge Kutta method.

Now, Runge Kutta are to German mathematician and they derived they first proposed this one fourth order fifth order. So, higher ordered Runge Kutta methods, but one of the way to derive the Runge Kutta method or to understand that how to obtain the Runge Kutta procedure is the one I explained there can be several other ways also for the second order, but if it is a fourth order or higher orders that becomes very complicated to derive. So, but advantage is that, this is has all the good thing; that means, it is higher order accurate and self-starting means you need to give that self-starting explicit scheme.

So, you need to give only the you need to provide only the solution at initial condition x equal to 0 and once that is provided. So, that is enough to obtain the subsequent solution. So, one of the generalization of this Runge Kutta second order method is the fourth order Runge Kutta method, which can be expressed in this way hm.

(Refer Slide Time: 23:49)

$$y_{n+1} = y_n + \frac{h}{2} [k_1 + k_2] \quad \text{Second-order Runge-Kutta Method.}$$

Self-starting, explicit scheme.

$$y_{n+1} = y_n + \frac{h}{6} (k_1 + 2k_2 + 2k_3 + k_4)$$

$$k_1 = f(x_n, y_n)$$

$$k_2 = f(x_n + \frac{h}{2}, y_n + \frac{h}{2} k_1)$$

$$k_3 = f(x_n + \frac{h}{2}, y_n + \frac{h}{2} k_2)$$

$$k_4 = f(x_n + h, y_n + h k_3)$$

Fourth-order Runge-Kutta Method

So, their fourth order Runge Kutta method is written this way y_{n+1} equal to y_n plus h by $6 k_1$ plus k_2 ; $2 k_2$ plus $2 k_3$ plus k_4 where k_1 is nothing, but $f(x_n, y_n)$ k_2 is $f(x_n$

plus h by $2 y_n$ plus y_n plus k_1 by $2 h$ in this case because sometime h is multiplied outside. So, here I have not done that.

So, $h k_1$ by $2 k_3$ is some type h by $2 y_n$ plus $h k_2$ by 2 and k_4 is little bit different. This is $f(x_n)$ plus $h y_n$ plus $h k_3$ $h k_3$. So, this is called the fourth order Runge Kutta method. So, this is a most popular again the same reason and it is of order h to the power 4. So, So, this is most popular as we stated it is a explicit and self-starting method and higher order scheme.

So, that is why in most of the cases the Runge Kutta methods are used to solve the initial value problem any kind of initial value problem you have. So, this is all about the discussion about the initial value problem for numerical solutions I wanted to make now. Why I brought this initial value problem to talk in the boundary value problem situation is now, what we will do is in certain cases that we can replace the given boundary value problem to a initial value problem.

(Refer Slide Time: 26:24)

§. Shooting Method for BVP

$$y'' = F(x, y, y'), \quad a < x < b$$

$$\left. \begin{aligned} \alpha_0 y(a) + \alpha_1 y'(a) &= \alpha_2 \\ \beta_0 y(b) + \beta_1 y'(b) &= \beta_2 \end{aligned} \right\} \text{ b.c.}$$

$$\alpha_0 + \alpha_1 > 0$$

$$\det \begin{matrix} \alpha_1 & \beta_1 \\ \alpha_0 & \beta_0 \end{matrix} = 0 \quad \left. \begin{aligned} y(a) &= \gamma_0 \\ y(b) &= \gamma_b \end{aligned} \right\} \text{ b.c.}$$

So, that kind of method is there is a class of method is referred as shooting method shooting method for BVP. So, this is the thing we will be talking now.

Now, a boundary value problem as I have said before is something like this, $f(x, y, y')$ x a bearing from a to b or 0 to a wherever you like and what conditions are can be given in different way, one of the way is; say in general it can be a form like $\alpha_0 \alpha_1 y$

dash a equal to alpha 2 beta 0 y a y b plus beta 1 y dash b equal to beta 2. So, this is the boundary conditions bcs.

Now, in this boundary conditions both the function value as well as function derivative are present. Now we first start with a simpler one. So, which normally that both alpha 0 and alpha 1 cannot be 0 so; that means, you should have this greater than 0. So, either of them alpha 0 can be 0 or alpha 1 can be 0, but both cannot be 0 if both is 0 then you do not have any boundary condition. So, that is ruled out now first we consider a situation where you have given the boundary conditions so; that means, let us take alpha 1 equal to beta 1 equal to 0; that means, a simpler situation.

So, what you have is y a is given to be some value y 0 and y b is given to be a value say yb. So, this is the bc for simplicity let this is the one.

(Refer Slide Time: 28:52)

It can be treated as an IVP if $y'(a)$ is known, which is the missing initial condition.

$y'(a) \rightarrow \text{given} \Rightarrow y(a) \rightarrow \text{missing initial condition.}$

Let $y'(a) = \alpha$

Equivalent IVP: $y'' = F(x, y, y')$,
 $y(a) = y_a, y'(a) = \alpha$

$$\begin{aligned} z &= \frac{dy}{dx}, \quad \frac{dz}{dx} = F(x, y, z) \\ y(a) &= y_a, \quad z(a) = \alpha. \end{aligned}$$

So, if this simple situation occurs now I can convert it to a IVP it can be treated as a IVP as an IVP Initial Value Problem if y dash a was known is known y dash a if this is this was given. So, could have been treated as IVP. So, this can be identified which we will referred as which is the missing initial condition.

Now, it may so, happen that you have given the solution at the two bound[ary]- on the derivatives are given at the two boundaries. So, in that case the function value itself is missing. So, so; that means, if you have given y dash a and y dash a. So, in that case you

can you have to choose if it is given, then $y(a)$ is missing initial condition. Now if I assume something. So, let $y'(a) = \alpha$, then how the problem looks like.

You have now. So, equivalent IVP initial value problem is $y'' = f(x, y, y')$ and $y(a) = y_a$ and $y'(a) = \alpha$. So, now, if I substitute $z = y'$. So, I get $dz/dx = f(x, y, z)$ and $y(a) = y_a$ and $z(a) = \alpha$. So, now, one can obtain a solution for this initial value problem because you have two set of equation, but they are coupled.

(Refer Slide Time: 31:38)

The image shows a whiteboard with handwritten mathematical notes. At the top, it says "initial condition." and "Let $y'(a) = \alpha$ ". Below that, it says "Equivalent IVP: $y'' = F(x, y, y')$, $y(a) = y_a, y'(a) = \alpha$ ". A box contains the system of equations: $z = \frac{dy}{dx}, \frac{dz}{dx} = F(x, y, z)$ and $y(a) = y_a, z(a) = \alpha$. An arrow points from this box to the text "Coupled set of IVP $-(*)$ ". Below the box, it says "We denote solun. of $(*)$ as $y(x; \alpha)$ ". In the bottom right corner, there is a small video inset of a man speaking.

So, coupled set of IVP. So, coupled means one solution is depending on the other, you cannot isolate the one from the other and need to be solved simultaneously both together.

So, now if I find the solution. So, I choose any arbitrary and I get a solution, but that cannot be the one which we are looking for the boundary value problem. So, what we need that it will be the equivalent initial value problem provided the solution whatever we obtain from this initial value problem equivalent initial value problem, must satisfy the other boundary condition.

So, that means, the solution of this if I call this star we denote solution of star as $y(x; \alpha)$ because the solution; obviously, depends on how the alpha was chosen. So, next lecture we will discuss that how alpha to be determined. So, that will be the procedure

that is the one will provide us to solve the modern value problem by converting to a equivalent initial value problem.

Thank you.
