Lecture - 03
Solution of BVPS by Eigen Function Expansion

Welcome back; now the same Eigen Function Expansion technique what we are discussing for ordinary differential equation or boundary value problem a single variable situation. Now, we will talk on the partial differential equations. Now partial differential equation and ordinary differential equation the main difference is that here the variables are more than one independent variables are involved say for example, u if u is a function of x and t u is a function of x and t .

(Refer Slide Time: 01:09)

So, in that case it is derivatives will have the partial derivative $\frac{\partial u}{\partial x}, \frac{\partial^2 u}{\partial x^2}, \frac{\partial u}{\partial t}, \frac{\partial^2 u}{\partial t^2}$ etcetera. So, this kind of things appears. So, in this situation then the partial differential equation involves so; that means, the differential equation which is a relation or equation which is involving the partial derivatives are referred as the partial differential equation. We have little bit discussion on these partial differential equations classification etcetera and the preambles already in the lecture 1.

Now, one of the important class of equation or important type of equation which we come across in heat transport equation or any kind of transport equation which is

governed by the diffusion mechanism. So, this follows this kind of equation $\frac{\partial u}{\partial t} = k \frac{\partial^2 u}{\partial x^2}$. This is again a boundary value problem it is the initial boundary value problem because t is involved.

So, you have a boundary say x can vary between 0 to say certain finite region 0 to l and t which is the time can be positive direction. Now, if we have a situation where l is say finite then the same expansion technique what we discussed in the previous lectures can be applicable here as well if the boundary is finite boundary for this linear equation linear another important things the homogeneous equation for equation is finite. For the time being we are not talking about what we will do with the if it is a infinite domain. So, that will come in due course of time.

So, for the time being we are considering a x is varying between 0 to l ; l is a finite number and u is satisfying a partial differential equation which is also called the parabolic PDE and t is the time $t = 0$. So, what we have is the boundary condition; that means, this is the B.C. We are writing say we impose again I made a mistake this is not x .

So, we impose homogeneous boundary condition so; that means, $u(0, t) = u(l, t) = 0$ homogeneous. So, far we are restricting to homogeneous equation homogeneous boundary condition and initial condition I.C. So, initial condition we are writing as $u(x, 0) = f(x)$ for $0 < x < l$ and this is happening for any $t > 0$ and this is happening for any x within the domain 0 to l .

So, this combined. So, you have a situation you have a differential equations with the conditions given by boundary condition $u(0, t) = u(l, t)$ and initial condition $u(x, 0) = f(x)$. This combined situation is referred as the initial boundary value problem and this if we want to make a correspondence with the physical significance. So, it is a one can say that heat conduction equation.

So, this is a heat conduction equation. So, basically what it represents a thin rod say of length say this is x a thin rod of length l which was initially heated with some temperature effects a temperature distribution initially was $f(x)$ and at the 2 end it has a fixed temperature it is maintained at 2 fixed temperature which are as a reference temperature.

So, let us call it 0 so, at this 2 end. So, then finding the heat distribution at any time at any point that satisfied the heat conduction equation and k is the conductivity of the material. So, if it is a iron or silver or copper so, k changes. So, basically this is our problem is to solve. So, this is heat conduction equation. Now, what we can start doing is that the equation is homogeneous and boundary conditions are homogeneous.

(Refer Slide Time: 07:15)

1) Homogeneous eqn. with homogeneous b.c.

We look for a solun as $u(x,t) = X(x)T(t) \neq 0$

$X(x), T(t)$

$u_t = k u_{xx}$

$\frac{X''}{X} = \frac{\dot{T}}{kT} = \text{constant} = \alpha, \text{ say}$

as l.h.s. is a fun of x only & r.h.s is a fun. of t only and they are equal for x & $t \Rightarrow$ each sides are equal to a constant.

$\frac{X''}{X} = \alpha,$

$X = A e^{\alpha x} + B e^{-\alpha x}$

$\Rightarrow A + B = 0, A e^{\alpha l} + B e^{-\alpha l} = 0$

$\Rightarrow A = B = 0,$ which leads to $X = 0$

$\dots u = 0,$ the trivial solution

B.C. $u(0,t) = u(l,t) = 0$
 $\Rightarrow X(0) = X(l) = 0$

So, what we have a homogeneous equation with homogeneous boundary condition; homogeneous boundary condition. I am repeating the same thing several times this homogeneous thing. So, homogeneous bc; I think that is enough to say that it is a homogeneous bc.

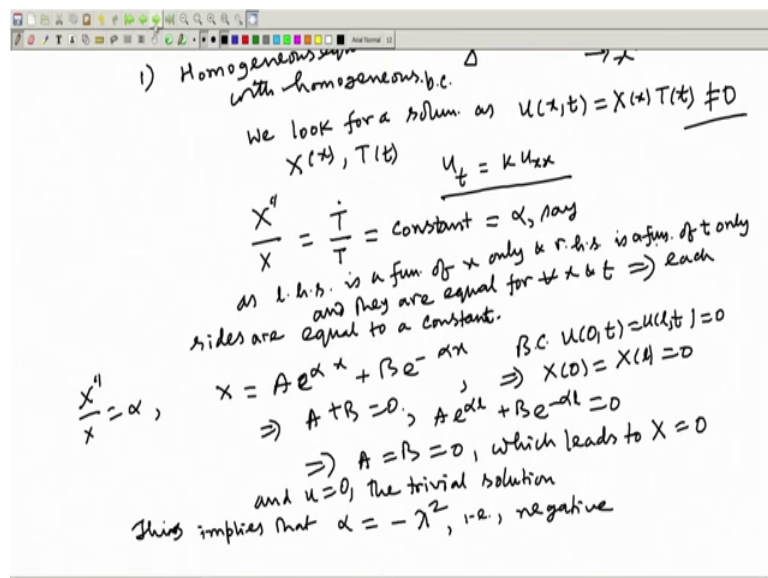

So, we look for a solution as $u(x,t)$ equal to $X(x)$ and $T(t)$. So, in other words X is the function of X is function of x only and T is a function of t only ok. So, we look for a solution as $u(x,t)$ equal to $X(x)$ equal and $T(t)$. So, if I substitute. So, our equation is u_t equal to $k u_{xx}$. So, if I substitute so, what I get? X'' by X equal to $\frac{\dot{T}}{kT}$ this relation we get. Now, this l.h.s is a function of x and r.h.s is a function of t . So, this has to be a constant as l.h.s is a function of x only and r.h.s is a function of t only and this is happening this relation is happening for any x and t .

So, for that what we must have that these should be equal to a constant. Now, let us take this constant equal to some say α say. Now, this is a purely function of x it is purely function of t and they are equal all the time all the time all the x is a function of t and

they are equal for all x and t . So, this implies a constant ratio is a each side is a each sides are equal to a constant. Now, if we take this a constant as α . So, what we can write is $X'' = \alpha X$.

So, what I can write as $X = Ae^{\alpha x} + Be^{-\alpha x}$. Sorry why I am sorry why should not be there. So, this is nothing, but αx and $Ae^{\alpha x} + Be^{-\alpha x}$. Now, what we boundary condition is homogeneous boundary condition. So, $u(0, t) = u(l, t) = 0$. So, this implies $X(0) = X(l) = 0$. So, what do you find that this implies that $A + B = 0$ and also $Ae^{\alpha l} + Be^{-\alpha l} = 0$.

(Refer Slide Time: 11:41)

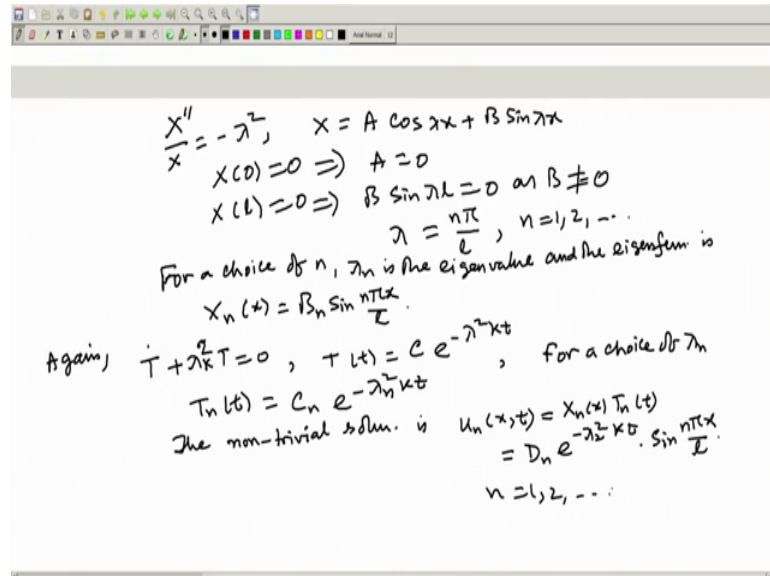

So, this implies $A = B = 0$ which leads to a trivial solution $X = 0$ and $u = 0$ the trivial solution, but basically we are interested to find out a non-trivial solution so; that means, what we are interested that this should not be equal to 0. If it is equal to 0 then it is a trivial solution and always since it is a homogeneous equation trivial solution is 0 solution is on always a possibility. So, we are looking for a solution which is not 0.

So, what it implies then that this implies that this constant should be equal to a this implies that α is a negative constant that is negative. It cannot be positive if it is positive then we have a difficulty we will have a trivial situation. So, α should be

negative. So, if alpha equal to minus lambda square negative means I can take as minus lambda square.

(Refer Slide Time: 13:23)

$$\begin{aligned}
 X'' &= -\lambda^2 X, & X &= A \cos \lambda x + B \sin \lambda x \\
 X(0) &= 0 \Rightarrow & A &= 0 \\
 X(l) &= 0 \Rightarrow & B \sin \lambda l &= 0 \text{ as } B \neq 0 \\
 & & \lambda &= \frac{n\pi}{l}, \quad n=1, 2, \dots \\
 & \text{For a choice of } n, \lambda_n \text{ is the eigenvalue and the eigenfun. is} \\
 X_n(x) &= B_n \sin \frac{n\pi x}{l} \\
 \text{Again, } T + \lambda^2 T &= 0, & T(t) &= C e^{-\lambda^2 t}, \quad \text{for a choice of } \lambda_n \\
 T_n(t) &= C_n e^{-\lambda_n^2 t} \\
 \text{The non-trivial soln. is } & u_n(x,t) &= X_n(x) T_n(t) \\
 & &= D_n e^{-\lambda_n^2 t} \sin \frac{n\pi x}{l} \\
 & & n=1, 2, \dots
 \end{aligned}$$

So, what I find is X'' equal to X equal to minus lambda square. So, this gives you X equal to $A \cos \lambda x$ plus $B \sin \lambda x$ because now it is e to the power i to the power situation. So, now, if I apply the boundary condition; so, $X(0)$ equal to 0 implies what this implies A equal to 0 because this is out and $X(l)$ equal to 0 implies $B \sin \lambda l$ equal to 0 . Now B cannot be 0 as B is not equal to 0 because again it will lead to a trivial solution u_n . So, this means \sin . So, λl should be equal to $n \pi$; so, $n \pi$ by l ok.

So, this is n equal to $1, 2, 3$ etcetera; so, this λ_n for a value of for a choice of n . So, λ_n the λ_n is the eigenvalue and the corresponding eigenfunction X_n equal to x_n in this case X_n equal to one can write as $B_n \sin \frac{n \pi x}{l}$. So, this is our eigenfunction. Now with the eigenfunction; now also we have to find out that T again $T \dot{+} \lambda^2 T = 0$ [FL]. Here it is a we have written λ^2 . So, $\lambda^2 T$ equal to 0 and so what I get is $T(t)$ equal to $\sum C e^{-\lambda^2 t}$. There is one K was missing K was missing yeah this is will be K . So, this is a K .

So, we have to put K over here. So, please note the change. So, K should come over here. So, $\lambda^2 K$ will turn over here.; so, e to the power $C e$ to the power minus $\lambda^2 K t$ or κt whatever way. Now for a for a given n for a choice of n

some lambda n say eigenvalue. So, you can find out the write down the $T_n t$ is $C_n e^{-\lambda_n^2 K t}$. So, the non-trivial solution is $u_n(x,t)$ equal to X_n into C_n . So, $X_n \times T_n t$ and we can write as some new constant say $D_n e^{-\lambda_n^2 K t}$ into $\sin \frac{n\pi x}{l}$ equal to $\frac{1}{2}$ etcetera. Now, each of these $u_n(x,t)$ are satisfying the our homogeneous equation.

(Refer Slide Time: 18:03)

Handwritten notes on a whiteboard:

$$u(x,t) = \sum_{n=1}^{\infty} D_n e^{-\lambda_n^2 K t} \sin \frac{n\pi x}{l}$$

$$= \sum_{n=1}^{\infty} D_n e^{-\frac{n^2 \pi^2 K}{l^2} t} \sin \frac{n\pi x}{l}$$

Since $u(x,0) = f(x)$

$$f(x) = \sum_{n=1}^{\infty} D_n \sin \frac{n\pi x}{l}$$

Multiply both sides by $\sin \frac{m\pi x}{l}$ and integrate between 0 to l

$$\int_0^l f(x) \sin \frac{m\pi x}{l} dx = \sum_{n=1}^{\infty} D_n \int_0^l \sin \frac{m\pi x}{l} \sin \frac{n\pi x}{l} dx$$

So, the general solution will be any combination of this; that means, $u(x,t)$ is nothing, but $\sum D_n e^{-\lambda_n^2 K t}$ we should have written the λ_n^2 in the form $\frac{n\pi^2}{l^2}$. So, basically this is λ_n^2 . So, n equal to 1 to infinity; so, this is $\sum_{n=1}^{\infty} D_n e^{-\lambda_n^2 K t} \sin \frac{n\pi x}{l}$.

So, now, what I left is to find out the D_n and we get the solution. Now D_n can be obtained by using the condition another initial condition. Now since $u(x,0)$ what we have is $u(x,0)$ equal to $f(x)$. So, one can write as $f(x)$ equal to $\sum_{n=1}^{\infty} D_n \sin \frac{n\pi x}{l}$. So, again the orthogonality property of the eigenfunctions $\sin \frac{n\pi x}{l}$ are the eigenfunctions.

So, I can use the orthogonality property. So, what we have to do is multiply both sides by $\sin \frac{m\pi x}{l}$ and integrate between 0 to l. So, what I get is $\int_0^l f(x) \sin \frac{m\pi x}{l} dx$ equal to $\sum_{n=1}^{\infty} D_n \int_0^l \sin \frac{m\pi x}{l} \sin \frac{n\pi x}{l} dx$.

Now, these are the orthogonal functions because they are forming the they are forming the eigenfunctions they are also this is a sign property.

(Refer Slide Time: 21:05)

$$D_m = \frac{2}{l} \int_0^l f(x) \sin \frac{m\pi x}{l} dx$$

$$u(x,t) = \sum_{n=1}^{\infty} \left[\frac{2}{l} \int_0^l f(x') \sin \frac{n\pi x'}{l} dx' \right] e^{-\frac{n^2\pi^2 K t}{l^2}} \sin \frac{n\pi x}{l}$$

So, what you can do is what we find that if I when I sum up sum over n. So, when n equal to m then only this term will be non-zero and remaining terms all will be 0. So, what we get here is D m and this integral will be nothing, but l by 2. So, and. So, what we get is D m is 2 by l 0 to l f x sin m pi x by l dx. So, I find out the constant in terms of the initial condition. So, whatever was prescribed.

So, u x t we can now write as u x t which is the solution of the heat conduction equation sigma 1 to infinity 2 by l 0 to l f x dash because they are the integration variable instead of writing the variable x dash which is our function variable. So, e to the power minus n square pi square by l square K square t if a pi square K t sin n pi x by l yeah n square pi square K by l; n square should have been because lambda n square is l square n pi by l. So, this is l square.

(Refer Slide Time: 23:21)

Handwritten notes on a whiteboard showing the solution of a PDE with non-homogeneous boundary conditions using eigenfunction expansion.

$$u(x,t) = \sum_1^{\infty} \left[\frac{2}{L} \int_0^L f(x') \sin \frac{n\pi x'}{L} dx' \right] e^{-\frac{n^2\pi^2}{L^2} kt} \sin \frac{n\pi x}{L}$$

which is the soln. in terms of the eigenfunctions

Non-homogeneous b.c.
 $u(0,t) = 1, u(L,t) = 0 \rightarrow$ B.c.
 $u_t = k u_{xx};$ I.c. $u(x,0) = f(x)$

$$u(x,t) = v(x,t) + w(x,t)$$

$w(0,t) = 1, w(L,t) = 0; w_{xx} = w_t$
 $w(x,0) = 0.$

Solve For $v(x,t)$ when $v_{xx} = kv_t, 0 < x < L, t > 0$
 $v(0,t) = v(L,t) = 0, t > 0$
 $v(x,0) = f(x), 0 < x < L$

$$u(x,t) = v(x,t) + \left(1 - \frac{x}{L}\right).$$

So, this is the solution of the which is the solution in terms of the eigenfunctions eigenfunctions. So, as a eigenfunction expansion we could obtain the solution for this kind of homogeneous PDE homogeneous partial differential equation with homogeneous boundary condition. Now here one point to note that we have taken the boundary condition to be homogeneous, but we may not be lucky all the time that we will have a; so, homogenous boundary condition.

Now that can be violated. So, say if may have a non-homogeneous boundary condition. So, in that case a non-homogeneous situation say you may have a situation like this $u(0,t)$ equal to 1 and say the other one is 0. So, now, this is a simple example discussing. So, what we do that u_t is equal to $K u_{xx}$ and of course, this is the B c and I c is as usual say $u(x,0)$ equal to $f(x)$.

Now what you have to do is one trick is this that I substitute $u(x,t)$ equal to say $v(x,t)$ such that it is taking the homogeneous boundary condition with homogeneous equation plus say sum $w(x,t)$ such a way that $w(x,t)$ satisfy the given parabolic PDE and also it is taking care of the homogeneous boundary non-homogeneity so; that means, I need $w_{xx} = w_t$
 $w(0,t) = 1$ and $w(L,t) = 0$.

And in addition w_{xx} equal to w_t that need to be satisfied. Now I can choose these and also these w because at t equal to 0. So, what we have is $w(x,0)$. So, that has to be 0. So, one simple situation say $w(x,t)$ I can take as just thing like this one ok. So, $1 - \frac{x}{L}$

minus x by l so, if I take 1 minus x by l . So, first of all it is steady distribution. So, for any time 1 minus x by l ; so, it satisfy these equation and also it is a 0 t and w l t is 0 w l t is 0 and w 0 t is 1 . So finally, an one can solve for v x t with homogeneous equation when v xx equal to k v t for 0 less than x less than l t greater than 0 and since u x t equal u 0 t is taken care by w 0 t . So, what you have is 0 t equal to v l t equal to 0 , but t greater than 0 and the initial condition is unperturbed because w is independent of t . So, initial condition was as usual x 0 equal to the same thing f x or 0 less than x less than l .

So, finally, we can write the solution as whatever you find out the solution in the series expansion form as we discussed before then substitute v x t plus 1 minus x by l which is the no. So, this is one way of taking care of the non-homogeneous situation non-homogeneous boundary condition.

So, so likewise this non homogeneity can be smartly avoided or can be taken into account whenever it appears in the boundary condition. So, for separation of variable technique or for that matter the Fourier series expansion or eigenfunction expansion is also referred as Fourier series expansion. I do not want to use the term because we are not using the Fourier series for the time being.

So, in the in that case what we need is a what I need is the domain to be finite equation to be homogeneous boundary condition to be homogeneous. If not some tricks to be adopted, but of course, domain has to be finite that is another.

(Refer Slide Time: 29:21)

Non-homogeneous

$$\frac{\partial u}{\partial t} = \frac{\partial}{\partial x} \left[p(x) \frac{\partial u}{\partial x} \right] + q(x)u + F(x,t), \quad a \leq x \leq b, t > 0.$$

$$B.C. \begin{cases} \alpha_1 u(a,t) + \alpha_2 u'(a,t) = 0 \\ \beta_1 u(b,t) + \beta_2 u'(b,t) = 0 \end{cases} \rightarrow \text{Homogeneous}$$

I.e. : $u(x,0) = f(x), \quad a < x < b.$

$$L[u] \equiv \frac{\partial}{\partial x} \left[p(x) \frac{\partial u}{\partial x} \right] + q(x)u$$

$$u_t = L[u] + F(x,t)$$

Let, $F=0$ then a homogeneous problem results
 $u(x,t) = X(x)T(t)$

Another condition to be imposed; now if we have a non-homogeneous situation say we have a equation like this $\frac{\partial u}{\partial t} = \text{say we have a situation like this say this is the } l \times p \times \frac{\partial u}{\partial x}$ in general I am writing any general form $q \times u$ plus $f \times t$ with the say finite boundary of course. So, in this case this equation has a non homogeneous term $f \times t$ and boundary conditions.

Let us assume Bc's are homogeneous bc's are u. So, let us take $\alpha_1 u + \alpha_2 u - a t = 0$ and $\beta_1 u + \beta_2 u - b t = 0$. This is a problem $u + b t = 0$. So, this is a homogeneous Bc and the initial condition I have only one should have only one because first order derivative in x so, $f \times x$. Now here if we want to find out the solution in that expansion situations. So, I introduced this operator $l u$ as $\frac{\partial}{\partial x} p \times \frac{\partial u}{\partial x} + q \times u$.

So, what I can write this equation as $u_t = l u + f \times t$. If $f = 0$ that is the previous the same way as we proceeded before can be obtained; so, let first assume that $f = 0$. So, in the same process if we obtain the solution so; that means, then it is the homogeneous problem results. So, we look for the solution $u(x, t) = X(x) T(t)$ separation of variable.

(Refer Slide Time: 32:45)

$u_t = L[u] + f(x, t)$
 let, $f = 0$ then a homogeneous problem results
 $u(x, t) = X(x) T(t) \rightarrow$ separation of variable
 $\frac{L[X]}{X} = \frac{\dot{T}}{T} = \text{constant} = \lambda$
 $L[X] = \lambda X, \quad a \leq x \leq b$
 $\alpha \frac{dT}{dt} = \lambda T, \quad t > 0$
 $\left. \begin{aligned} \alpha_1 X(a) + \alpha_2 X'(a) &= 0 \\ \beta_1 X(b) + \beta_2 X'(b) &= 0 \end{aligned} \right\} \text{ b.c.}$
 $T(0) = f(x), \quad a \leq x \leq b$
 let λ_n & $u_n \rightarrow$ be the eigen value & eigenfun., respectively.
 or $L[X] = \lambda X$

So, if I succeed there this is not this term is not there. So, what we have is $l X$ by X equal to T dot by T equal to some constant and that constant say let us take some λ . So,

what I get is $l X$ equal to λX so; that means, say eigenvalue situation for a less than x less than b and $d T$ equal to λT for t greater than 0 .

So, λ is the separation constant and what we have here is $\alpha_1 \sin \alpha_1 x + \alpha_2 \cos \alpha_1 x = 0$ and $\beta_1 \sin \beta_1 x + \beta_2 \cos \beta_1 x = 0$ and this is the bc and what we have is $t > 0$ equal to $f(x)$ this is our ic $a < x < b$. So, one can find out the eigenvalues. So, let us call let λ_n and u_n be the eigenvalues and I am sorry eigenvalues eigenvalue and eigenfunction respectively. So, this can be obtained of say $l x$ equal to λx .

So, this can be obtained and then we will apply the this eigenvalues expansion technique to find out the solution for the non-homogeneous case. So, this is I think we will continue in the next lecture. So, the same way we have to obtain that xx . So, say let us call this $u(x, t)$. So, if I call λ_n u_n . So, we get $a(x, n, x)$ and $t(n, t)$. So, this is the thing we will continue in the next lecture.

Thank you.
