Lecture - 08
Green's Function for BVP and Dirichlet Problem (Contd.)

Welcome back. So, now, we will talk about the homogeneous equation Green's function that we have constructed are the previously. So, which was this is the form; now we will go by an example a simple example.

So, basically what we did is we have a just to revise our previous one we have a non homogeneous boundary value problem and then we have two independent solution for the homogeneous boundary value problem. So, and based on that, we have constructed the Green's function.

(Refer Slide Time: 01:16)

Ex. $y'' = f(x)$, $y(0) = 0$, $y(1) = 0$, $0 < x < 1$.

Homogeneous eqn. $y'' = 0$

Solutions are $1, x$.

$G_1(x; y) = C_1(y) u_1(x)$, $0 < x < y$

$G_1(0; y) = 0$,

$G_1(x; y) = x C_1(y)$.

$G_2(x; y) = C_2(y) u_2(x)$, $y < x < 1$

$G_2(1; y) = 0$,

$G_2(x; y) = C_2(y) \cdot (1-x)$, $y < x < 1$.

Now, let us take a example simple example say given by this way say $y'' = f(x)$, $y(0) = 0$ and $y(1) = 0$. So, our domain is $0 < x < 1$, now this is the domain. So, this is a very simple one. So, the homogeneous one homogeneous equation first of all we have to find out the fundamental solutions $y'' = 0$.

So, we can have solutions are 1 and x any combination of that. So, we construct a Green's function. So, $G_1(x; y)$ say $C_1(y)u_1(x)$ for $0 < x < y$ and it has to be in such a way that G_1 it should be $G_1(0; y)$ should be equal to 0 so. So, now, I if I choose, so, for that I choose $G_1(x; y)$ I choose as x into $C_1(y)$ into $C_1(y)$ and the other part $G_2(x; y)$. So, this will be $C_2(y)u_2(x)$ for $0 < y < x < 1$, $y < x < 1$. So, what I need is G_2 should be $G_2(1; y)$ should be equal to 0.

So, we choose u_2 . So, we choose the $G_2(x; y)$ as $G_2(x; y)$ we choose as $C_2(y)$ into $1 - x$ which is valued for $0 < y < x < 1$ ok. So, now, we need to find out C_1 C_2 .

(Refer Slide Time: 04:13)

The image shows a handwritten derivation in a windowed environment. The text is as follows:

$$G_1(1; y) = 0,$$

$$G_2(x; y) = C_2(y) \cdot (1-x), \quad 0 < y < x < 1$$

$$u_1 = x, \quad u_2 = 1-x$$

$$W = \begin{vmatrix} x & 1-x \\ 1 & -1 \end{vmatrix} = -1.$$

$$G_1(x; y) = \begin{cases} x(y-1), & 0 < x < y \\ y(x-1), & y < x < 1 \end{cases}$$

Soln. of the non-homogeneous eqn. $L[u] = f$

$$u(y) = \int_0^1 G_1(x; y) f(x) dx$$

$$= \int_0^y G_1(x; y) f(x) dx + \int_y^1 G_2(x; y) f(x) dx.$$

So, now w for this case, so, u_1 is our in the situation is x and u_2 is $1 - x$. So, w is $x(1 - x) - 1(1 - x)$. So, this becomes -1 ok. So, Wronskian is -1 and what we need to find out.

So, $G(x; y)$ if I apply that formula, so, that becomes x into $y - 1$ for $0 < x < y$ and y into $x - 1$ when $y < x < 1$. So, the solution of the non homogeneous equation $L u = f$ is $u(x) = \int_0^1 G(x; y) f(y) dy$. So, whichever way either if I go by this manner. So, better I should do this way I write $u(y) = \int_0^y G_1(x; y) f(x) dx + \int_y^1 G_2(x; y) f(x) dx$ is either way I can take because of symmetry. So, this becomes $\int_0^y G_1(x; y) f(x) dx + \int_y^1 G_2(x; y) f(x) dx$.

(Refer Slide Time: 06:30)

Handwritten mathematical derivation showing the Green's function $G(x; y)$ for a boundary value problem. The function is defined as:

$$G(x; y) = \begin{cases} x(y-1), & 0 < x < y \\ y(x-1), & y < x < 1 \end{cases}$$

Soln. of the non-homogeneous eqn. $L[u] = f$

$$u(y) = \int_0^1 G(x; y) f(x) dx$$

$$= \int_0^y G(x; y) f(x) dx + \int_y^1 G(x; y) f(x) dx$$

Let $f(x) = x^2$

$$u(y) = \int_0^y x^2(y-1) dx + \int_y^1 x^2 y(x-1) dx$$

$$u(y) = \frac{1}{12} (y^4 - y)$$

So, for example, if I choose let $f(x)$ equal to x^2 . So, in that case $u(y)$ will be $\int_0^1 x^2(y-1) dx + \int_y^1 x^2 y(x-1) dx$. So, this gives you $\frac{1}{12} (y^4 - y)$. So, this is the simple way to find out the solution of this non homogeneous equation. So, this is one of the example of course, one can solve it straight away.

So, this Green's function basically what we transform the differential equation now to a integral equation. So, some cases integral equation is easier to solve.

(Refer Slide Time: 08:07)

Handwritten mathematical derivation showing the Green's function for a Sturm-Liouville problem. The differential equation is:

$$L[u] \equiv (pu')' + qu = \lambda u, \quad 0 < x < a$$

$G(x; y)$ is the Green's function for L

Then, $L_x G = \delta(x-y)$

$$L_x G \cdot \lambda u = \delta(x-y) \lambda u$$

$$\int_0^a \lambda u L_x G(x; y) dx = \int_0^a \lambda u \delta(x-y) dx$$

$$L_x \left[\lambda \int_0^a u(x) G(x; y) dx \right] = \lambda u(y)$$

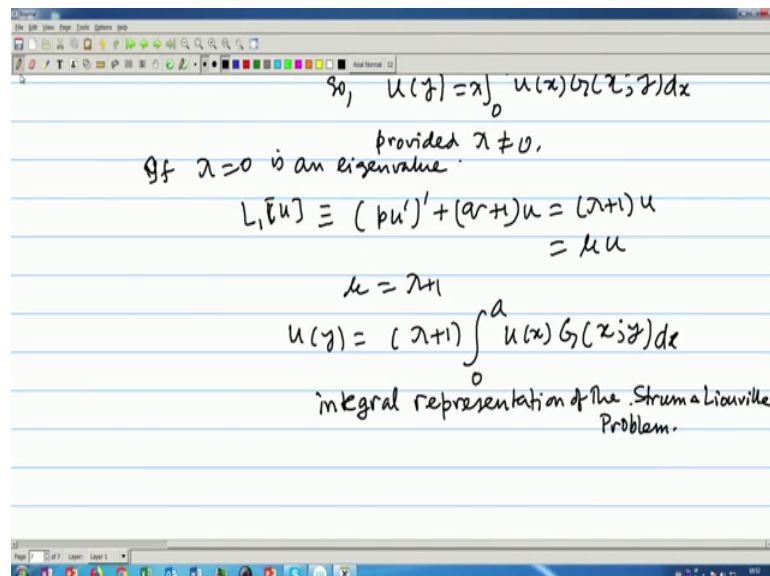

So, $u(y) = \int_0^a u(x) G(x; y) dx$

Now, the Sturm-Liouville problems the Green's function for Sturm-Liouville problem can also be defined like this way. So, we have this Sturm-Liouville problem given by $p u'' + q u = \lambda u$, say $0 < x < a$. I have frequently used either $0 < x < a$ or $a < x < b$ both are same I can transform the coordinate instead of $x = a$, I can make it $x = 0$ there is no harm in. So, it should not be confusing.

Now, if $G(x, y)$ so if this is a homogeneous problem Sturm-Liouville problem. So, if $G(x, y)$ is the Green's function of the operator $L u$ say $G(x, y)$ is the Green's function for L then what we will have is $L x G = \delta(x - y)$ and so, if I now multiply by λu both side $\lambda u \delta(x - y) = \lambda u$ and integrate and then integrate between 0 to a . So, $\lambda u \int_0^a \delta(x - y) dx = \lambda u \int_0^a \delta(x - y) dx$ and that gives you λu and this side will be $L x$ can be taken away. So, 0 to a . So, λ is out is a constant.

Say $0 < a$ $u(x) G(x, y) dx = \lambda u$. So, in other words the solution is. So, I get a solution $u(y) = \int_0^a u(x) G(x, y) dx$. So, this is a (Refer Time: 11:26) type integral equation, but the problem here problem here is. So, there will be a λ inside.

(Refer Slide Time: 11:40)

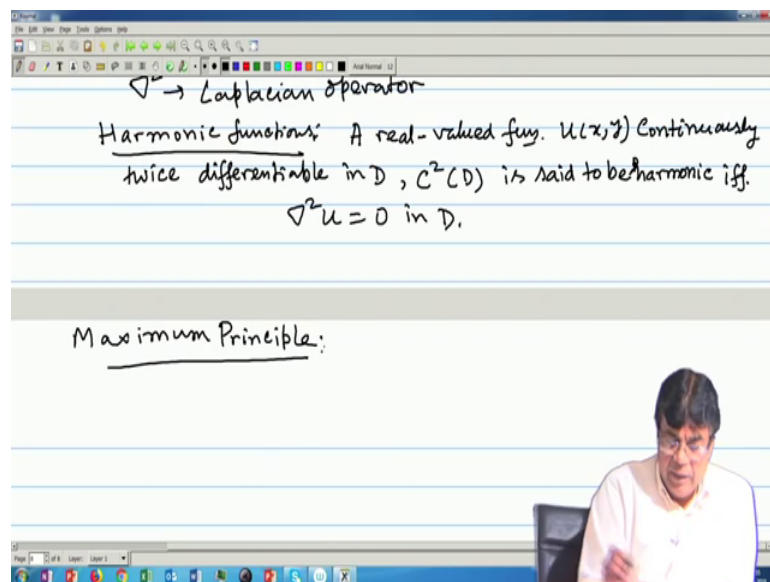

So, provided λ is not equal to 0 . So, a integral equation representation is given by this way. So, if $\lambda = 0$, we can do little modification is an Eigen value of L of this Sturm-Liouville problem.

So, we can modify this way in (Refer Time: 12:12) like is an Eigen value then what we do is we can modify we just write the modified form this way $\Delta u + q u = \lambda u$. So, this I call as μu . So, in that case μ is nothing, but $\lambda + 1$. So, I can do the sum operation and get a integral representation as 0 to a $\int_{\Omega} G(x,y) dx$ in this case the $G(x,y)$ is the Green's function of L .

So, this is an equivalence with the Sturm-Liouville problem integral representation integral representation of the Sturm-Liouville problem. I am sorry I am now Green's function is not a very simple procedure as we could see that it leads to a ordinary differential equation a differential equation to an integral equation.

So, now, all the time it may not be a very helpful 1, but in some cases only the boundary value problems and all the Green's function is found to be little useful particularly the heat conduction Laplace a Parisian type of equation of course, Parisian type of equation with the Laplace operator basically what I mean. So, now we will construct the Green's function for the desolate problem or the Laplace type of equation.

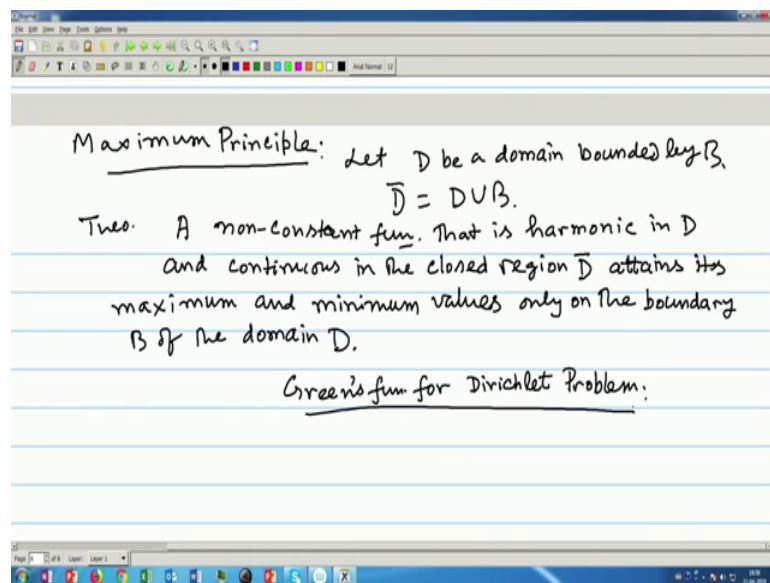

(Refer Slide Time: 14:45)

Now, before that; that means, we will be talking about these situations del 2 Laplacian operator. Now define a harmonic function. Basically the harmonic functions are which solves this $\Delta u = 0$.

So, we define in this way a real valued function $u(x, y)$ continuously twice differentiable in a interval a, b in D say in a domain d we will also write as $C^2(D)$ is said to be harmonic if and only if said to a harmonic even only if $\Delta^2 u = 0$ in d . So, harmonic function has to satisfy the Laplace equation; now there are certain important property of this harmonic function one is the maximum principle this says that the all the maximum or minimum of u will attend at the boundary of the domain.

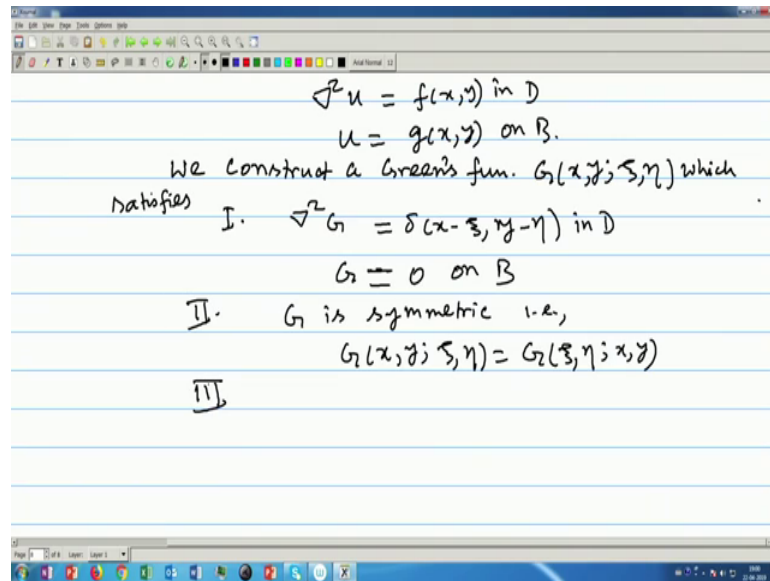

(Refer Slide Time: 16:45)

So, let D be a domain bounded by B say it can be rectangle or a circle or spherical or whatever and we call \bar{D} equal to D union B . So, theorem is the principle of the maximum principle is a non constant function that is harmonic in D and continuous in the closed region \bar{D} which is nothing, but D plus the boundary attains its maximum and minimum values only on the only on the boundary B of the domain D .

So, all these maximum and minimum whatever the extremum values will be attend it by the harmonic function on the boundary of the domain. So, this is referred as a maximum principle. Now our intention is to construct the Green's function for Dirichlet problem.

(Refer Slide Time: 19:26)

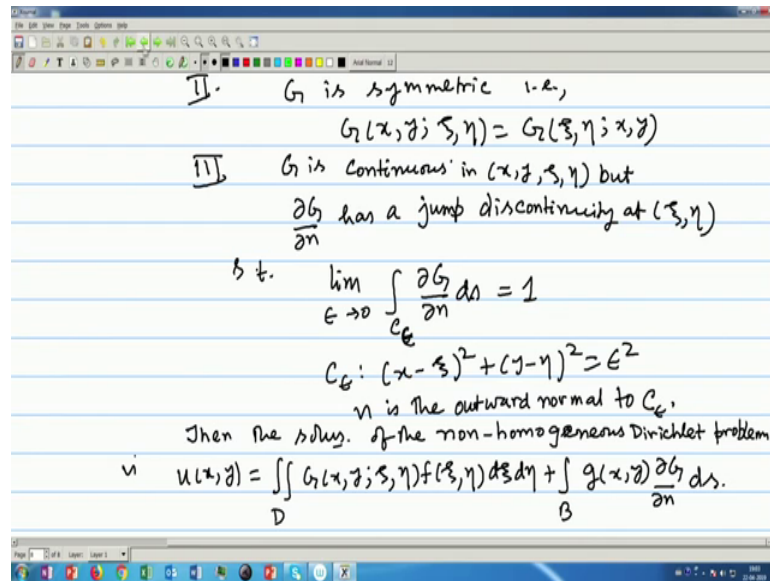

Now so; that means, we what we have is $\nabla^2 u$ equal to say $f(x, y)$ in D .

So, it is not a homogeneous boundary condition because we are talking about Dirichlet problem so; that means, u is prescribed on the boundary. So, maybe it can be also 0 on B . So, we consider we construct a Green's function, we define this way $G(x, y; \xi, \eta)$ which satisfies following condition I $\nabla^2 G = \delta(x - \xi, y - \eta)$ in D so; that means, it is harmonic everywhere etcetera ξ, η , I would say I will not say the harmonic in that sense because harmonic means it has to be 0.

So; that means, it is satisfying the Laplace equation everywhere except at ξ, η and $G = 0$ on the boundary on the boundary B , then second condition is G is symmetric that is what we can say that $G(x, y; \xi, \eta) = G(\xi, \eta; x, y)$.

(Refer Slide Time: 21:39)

Third it is continuous at x, y, ξ, η . G is continuous in x, y, ξ, η , but $\frac{\partial G}{\partial n}$ has a discontinuity. It has a jump discontinuity at ξ, η such that $\lim_{\epsilon \rightarrow 0} \int_{C_\epsilon} \frac{\partial G}{\partial n} d\sigma = 1$ where so; that means, if I enclose this ξ, η point by a circle C_ϵ is this circle plus y minus η whole square equal to ϵ^2 of radius ϵ . So, if n is the outward normal to C_ϵ .

So, So, this has a jump discontinuity a c surface area. So, you have a circle C_ϵ encircling the point ξ, η . So, as I contract the radius of this circle and approaching x, y, ξ, η then you have a jump discontinuity in the gradient or the derivative normal derivative given by this way. So, if I can construct a G based on these 3, then the solution then the solution of the non homogeneous homogeneous problem Dirichlet problem is given can be given this way $u(x, y)$ equal to double integral $G(x, y, \xi, \eta) f(\xi, \eta) d\xi d\eta$ is the area integral plus on the boundary $G(x, y) \frac{\partial G}{\partial n} d\sigma$.

So, this is the this is the construction of the solution can be expressed by this manner now. So, provided all these conditions are satisfied by G . Now to show that so, what we have is G satisfying this it is the Laplace equation homogeneous equation except an homogeneous boundary condition and symmetric and it has a jump discontinuity at the point ξ, η . Now, to prove that we have to use the Green's second identity.

(Refer Slide Time: 25:56)

Handwritten mathematical derivation on a digital whiteboard:

Top line:
$$\text{div } \vec{u} = \iiint_D (\frac{\partial u_x}{\partial x} + \frac{\partial u_y}{\partial y} + \frac{\partial u_z}{\partial z}) dV$$

Text: Gauss's divergence theo.:

Equation 1:
$$\int_V \text{div } \vec{u} dV = \int_S \vec{u} \cdot \vec{n} dS$$

Equation 2:
$$\vec{u} = \phi \nabla \psi$$

Equation 3:
$$\int_V (\phi \nabla^2 \psi + \nabla \phi \cdot \nabla \psi) dV = \int_S \phi \frac{\partial \psi}{\partial n} dS$$

Equation 4:
$$\int_V (\psi \nabla^2 \phi + \nabla \psi \cdot \nabla \phi) dV = \int_S \psi \frac{\partial \phi}{\partial n} dS$$

Now, recall that the Gauss divergence theorem what it says? The Gauss divergence theorem is integral over v any area or any region if I integrate. So, a function say v. So, that it will be v dot n ds over the surface.

Now, if I replace this v bar equal to some phi grad psi. So, what I get is phi. So, phi del to psi minus plus of course, phi del 2 psi grad phi dot grad psi d v equal to phi del psi del n d s s. Now same way if I write now if I construct this way psi grad phi. So, what I get is same way I just substitute here. So, psi del 2 phi plus grad phi dot grad phi dv equal to psi del phi del n d s. Now if I this is capital s or whichever way you can write.

(Refer Slide Time: 27:46)

$$\int_V (\nabla \cdot \psi + \psi \cdot \nabla \phi) dv = \int_S \psi \cdot \frac{\partial \phi}{\partial n} ds$$

$$\int_V (\psi \nabla^2 \phi + \nabla \psi \cdot \nabla \phi) dv = \int_S \psi \frac{\partial \phi}{\partial n} ds$$

Let $\phi = G(x, y, \xi, \eta)$, $\psi = u(x, y)$
 $V \rightarrow D$, $S \rightarrow B$

$$\iint_D (G \nabla^2 u - u \nabla^2 G) dx dy = \int_B \left[G \frac{\partial u}{\partial n} - u \frac{\partial G}{\partial n} \right] ds$$

$G = 0$ on B

$$\iint_D [G \nabla^2 u - u \nabla^2 G] dx dy = - \int_B u \frac{\partial G}{\partial n} ds$$

Now, I will subtract this two. So, what I get is, phi del minus to psi minus psi delta phi equal to dv equal to integral over s phi del phi del n minus phi del phi del n d s. Now let phi equal to G x y xi eta and xi is u x y and the domain v is our D and S is the. So, D is the area bounded by S, S is B. So, in that case what I get this is double integral because we are in the 2 dimension. So, this is phi G del 2 u minus u del 2 G d x d y equal to integral over B phi. So, d G del u del n minus u del G del n ds the line integral.

Now, you remember that G is 0 over B G equal to 0 and B and also G del 2 u minus u del x minus xi y minus eta. So, d x d y equal to minus B u del G del n ds. So, we have this u G del 2 u.

(Refer Slide Time: 30:18)

The image shows a digital whiteboard with handwritten mathematical derivations. The top part shows the derivation of the Green's function formula for a non-homogeneous Poisson equation. It starts with the equation $\nabla^2 u = f(x, y)$ in a domain D , with boundary conditions $u = 0$ on B . The derivation uses Green's second identity with $\phi = G(x, y; \xi, \eta)$ and $\psi = u(x, y)$. The final formula is $u(\xi, \eta) = \iint_D f(x, y) G(x, y; \xi, \eta) dx dy + \int_B g(x, y) \frac{\partial G}{\partial n} ds$. The bottom part shows the derivation of the symmetry property $G(\xi, \eta; \xi', \eta') = G(\xi', \eta'; \xi, \eta)$ by applying the same identity to $\phi = G(x, y; \xi, \eta)$ and $\psi = G(x, y; \xi', \eta')$, and using the boundary condition $G = 0$ on B .

$$\iint_D \left[G \nabla^2 u - u \nabla^2 G \right] dx dy = - \int_B u \frac{\partial G}{\partial n} ds$$

$$u(\xi, \eta) = \iint_D f(x, y) \cdot G(x, y; \xi, \eta) dx dy + \int_B g(x, y) \frac{\partial G}{\partial n} ds.$$

II Symmetry $\phi = G(x, y; \xi, \eta), \psi = G(x, y; \xi', \eta')$

$$\iint_D G(x, y; \xi, \eta) \cdot \nabla^2 G(x, y; \xi', \eta') dx dy - \iint_D G(x, y; \xi', \eta') \nabla^2 G(x, y; \xi, \eta) dx dy = 0$$

as $G = 0$ on B

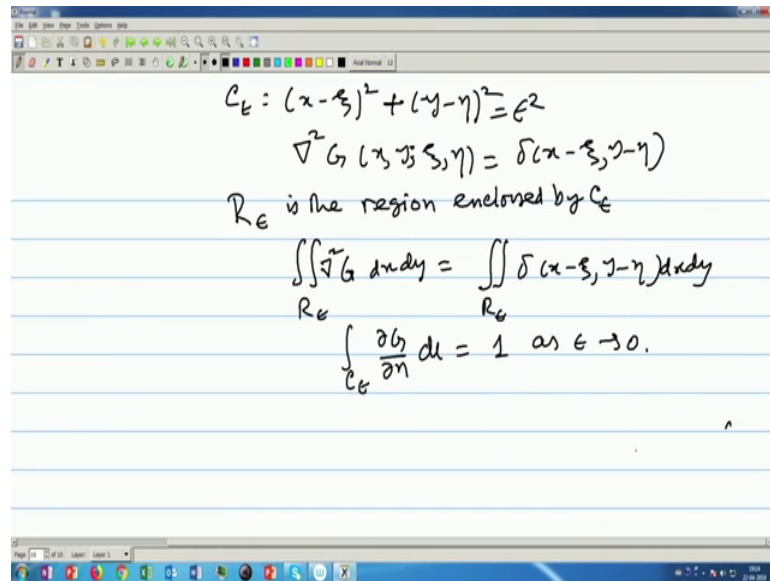

$$G(\xi, \eta; \xi', \eta') = G(\xi', \eta'; \xi, \eta) \rightarrow \text{Symmetry}$$

Now $\nabla^2 u$ is given to be $f(x, y)$ and this one so; that means, u what we have is $u(x, y)$. I now integrate this one. So, $u(x, y)$. So, I take out the minus. So, $u(x, y)$ my equal to I transfer to this side. So, double integral $D \nabla^2 u$ means $\int f(x, y) dx dy$ what was the what was our notation was equation was $\nabla^2 u = f(x, y)$.

So, $\nabla^2 u = f(x, y)$ into $G(x, y; \xi, \eta) dx dy$ plus u is given to be G . So, $G(x, y)$ $\frac{\partial G}{\partial n} ds$. So, this is what the yeah. So, I have notation was all correct. So, this is the solution of the non homogeneous equation in terms of the Green's function. So, this is also a very easy to show that the symmetry condition symmetry can be shown is that. So, this is a solution now, now symmetry say this second property the symmetry. So, the symmetry what we do is in that this is called the Gauss or Green's second identity this one. So, here what we put ϕ equal to say $G(x, y; \xi, \eta)$ and ψ equal to $G(x, y; \xi', \eta')$.

So, double integral $D G(x, y; \xi, \eta) \nabla^2 G(x, y; \xi', \eta')$ and $\nabla^2 G(x, y; \xi, \eta) G(x, y; \xi', \eta')$. So, $\nabla^2 G(x, y; \xi, \eta) G(x, y; \xi', \eta')$ I can write as $\nabla^2 G(x, y; \xi, \eta) G(x, y; \xi', \eta')$ minus $G(x, y; \xi, \eta) \nabla^2 G(x, y; \xi', \eta')$. So, this is $G(x, y; \xi, \eta) \nabla^2 G(x, y; \xi', \eta')$ minus $G(x, y; \xi', \eta') \nabla^2 G(x, y; \xi, \eta)$ equal to 0 as $G = 0$ on B . So, from here what I can find that this will be is $G(x, y; \xi, \eta) \nabla^2 G(x, y; \xi', \eta')$ equal to this is $G(x, y; \xi', \eta') \nabla^2 G(x, y; \xi, \eta)$ so; that means, symmetry. So, now, what we left here is to show that other one that is the jump condition.

(Refer Slide Time: 33:54)

The image shows a digital whiteboard with handwritten mathematical equations. The equations are:

$$C_\epsilon = (x - \xi)^2 + (y - \eta)^2 = \epsilon^2$$
$$\nabla^2 G(x, y; \xi, \eta) = \delta(x - \xi, y - \eta)$$

R_ϵ is the region enclosed by C_ϵ

$$\iint_{R_\epsilon} \nabla^2 G \, dx dy = \iint_{R_\epsilon} \delta(x - \xi, y - \eta) \, dx dy$$
$$\int_{C_\epsilon} \frac{\partial G}{\partial n} \, dl = 1 \text{ as } \epsilon \rightarrow 0.$$

Now, to show the jump condition, so, we consider that C_ϵ as $(x - \xi)^2 + (y - \eta)^2 = \epsilon^2$. Now $\nabla^2 G(x, y; \xi, \eta) = \delta(x - \xi, y - \eta)$. So, if I consider R_ϵ is the region enclosed by C_ϵ and then if I integrate over R_ϵ $\nabla^2 G \, dx \, dy$ is a R_ϵ $\delta(x - \xi, y - \eta) \, dx \, dy$.

So, this I can write as transformed to surface one area C_ϵ or the curve. So, this is $\nabla G \cdot \nabla n \, dl$ and this is becoming 1 as ϵ tends to 0. So, the discontinuity of jump discontinuity of this equation is satisfied. So, I will show 1 example 1 or 2 example.

(Refer Slide Time: 35:46)

$\nabla^2 \rightarrow$ Laplace operator
 $\nabla^2 G = \delta(x-\xi, y-\eta) \quad \text{---(a)}$
 $r = \sqrt{(x-\xi)^2 + (y-\eta)^2}$. Transform to polar coordinate
 The soln. of (a) can be
 $\frac{1}{r} \frac{\partial}{\partial r} \left(r \frac{\partial \bar{G}}{\partial r} \right) = 0$ except at $r=0$
 $\bar{G} = A + B \log r$
 $G = \bar{G} + g, \quad \bar{G} \neq 0$ on B .

So, now, if we have a Laplace operator Δ^2 is a say Laplace operator. So, if I choose. So, $\Delta^2 G$ if you to construct this Green's function. So, $\delta(x-\xi, y-\eta)$, say if I choose say R equal to a coordinate a polar coordinate if I choose with $y-\eta$ whole square; so, transferred to polar coordinate with pole at with pole at ξ, η . So, what I can find that if a solution of these. So, let us call this is a equation a the solution of a can be like this way I can write as if I transfer to polar coordinate.

And if I consider that this is a ΔG because it cannot be may not be Green's function; because Green's function means it has to have a homogeneous boundary condition. So, \bar{G} can be taken to be some $A + B \log r$. So, now, if I say that Green's function G equal to some \bar{G} plus small g .

So, that this \bar{G} may not be may not be 0 on boundary B . So, in that case I can find out the B by this manner.

(Refer Slide Time: 37:56)

The soln. of (1) can be

$$\frac{1}{r} \frac{d}{dr} \left(r \frac{dG}{dr} \right) = 0 \text{ except at } r=0$$

$$\bar{G}_0 = A + B \log r$$

$$G_1 = \bar{G}_0 + g, \quad \bar{G}_0 \neq 0 \text{ on } B_1.$$

$$\lim_{\epsilon \rightarrow 0} \int_{C_\epsilon} \frac{\partial G}{\partial n} ds = 1 \quad ds = r d\theta$$

$$\lim_{\epsilon \rightarrow 0} \int_{C_\epsilon} \frac{B}{r} \cdot r d\theta = 1 \cdot 2\pi B \Rightarrow B = \frac{1}{2\pi}$$

Let $A = 0$, $\bar{G}_0 = \frac{1}{2\pi} \log r$

Which needs to be modified to construct the Green's function such that it vanishes on the boundary.

Now, we know we can use this condition that $C_\epsilon \int \frac{\partial G}{\partial n} ds$ is equal to 1 now if it is a circle. So, ds can be $r d\theta$. So, this is a I can write as limit ϵ tends to 0. So, B by $r r d\theta C_\epsilon$ is equal to 1 so; that means, $2\pi B$ equal to 1. So, B equal to 1 by 2π . So, 1 can write and let A equal to 0.

So, G can be taken as $\frac{1}{2\pi} \log r$, but which needs to be modified to construct the Green's function to construct the Green's function] so, that such that it vanishes on the boundary. So, it is not a very furnaces on the boundary. So, it is not a very trivial task as such and there are quite a bit manipulations need to be done.

So, even for this kind of linear equation linear elliptic equation or Laplace equation linear Parisian type of equation we are finding is quite difficult. So, that is why the Green's function is only for typical cases one consider. So, most of these are all were very popular when before the super computer computers and all computing power technology are not that much developed. So, today I stop here my discussion on the Green's function. So, next class we will continue.

Thank you.
