So welcome back to lectures on Engineering Mathematics 2 and this is lecture number 16 on Cauchy Integral Formula.

(Refer Slide Time: 00:20)

The slide is titled "CONCEPTS COVERED" and lists the following topics:

- Cauchy Integral Formula
- ☐ Simply & Multiply Connected Domains
- Derivative of Analytic Functions
- Evaluation of Complex Line Integrals

So today we will cover the Cauchy integral formula for simply and multiply connected domains and then we will move to the derivative of analytic functions in terms of the integral we will see that we can find the derivative of an analytic function. And then we will go for some evaluation of complex line integrals with the help of Cauchy integral formula.

(Refer Slide Time: 00:46)

CAUCHY'S INTEGRAL THEOREM (RECALL)

If $f(z)$ is analytic in a simply connected domain D , then for every simple closed curve C in D , we have

$$\oint_C f(z) dz = 0$$

MORERA'S THEOREM (Converse of Cauchy's Theorem)

Let f be continuous in a simply connected domain D . If

$$\oint_C f(z) dz = 0$$

for every closed path C in D , then f is analytic in D .

So just to recall in the last lecture we have gone through the Cauchy integral theorem which says that if $f(z)$ is analytic in a simply connected domain D then every simple closed curve C in D we have this closed integral of $f(z)$ of this analytic function over a closed path is 0 so that was the Cauchy integral theorem and we have gone through several examples or applications based on this theorem for the evaluation of complex line integrals.

So today first let me just tell you that this Cauchy integral theorem there is called the reverse or the converse of this Cauchy integral theorem just to mention we are not going into the detail, we will directly move for Cauchy integral formula. So this Morera theorem says that if f is continuous in a simply connected domain D , so we are not talking about analyticity now here in the Cauchy theorem it was like f is analytic then we have this integral 0, now we are going other way round that if this integral is 0, so we have the assumption that f is continuous in a simply connected domain D .

And if we note that this integral is 0 for every closed path C in D then f is analytic, so in that way this is a converse of this Cauchy theorem because from the integral now you are telling that f is

analytic in D whereas in Cauchy theorem we say this f is analytic then this integral is 0 over any closed, a simple closed path C, so this is just to mention that there is a converse of Cauchy theorem as well.

(Refer Slide Time: 02:32)

CAUCHY INTEGRAL FORMULA

Let $f(z)$ be analytic in a simply connected domain D . Then for any point z_0 in D and any simple closed path C in D that encloses z_0 , we have

$$\oint_C \frac{f(z)}{z - z_0} dz = 2\pi i f(z_0)$$

NPTEL

CAUCHY INTEGRAL FORMULA

Let $f(z)$ be analytic in a simply connected domain D . Then for any point z_0 in D and any simple closed path C in D that encloses z_0 , we have

$$\oint_C \frac{f(z)}{z - z_0} dz = 2\pi i f(z_0) \quad \text{or} \quad f(z_0) = \frac{1}{2\pi i} \oint_C \frac{f(z)}{z - z_0} dz$$

Proof:

$$\begin{aligned} \oint_C \frac{f(z)}{z - z_0} dz &= \oint_C \frac{f(z_0) + (f(z) - f(z_0))}{z - z_0} dz \\ &= f(z_0) \oint_C \frac{1}{z - z_0} dz + \oint_C \frac{f(z) - f(z_0)}{z - z_0} dz \\ &= f(z_0) 2\pi i + \oint_C \frac{f(z) - f(z_0)}{z - z_0} dz \end{aligned}$$

NPTEL

So we will move to now the Cauchy integral formula, so there is a difference we are talking about the Cauchy integral theorem, now we are talking about the Cauchy integral formula. So what this formula says that if f is analytic in a simply connected domain D, so the similar assumptions what we have for Cauchy theorem then for any point z_0 in D and any simple closed path C we take in D that encloses this point z_0 .

We have this result that $\int_C \frac{f(z)}{z - z_0} dz$ is $2\pi i f(z_0)$, so this is the extra term here if this is not there then $\int_C f(z) dz$ was 0 but we have now $\frac{f(z)}{z - z_0}$, so as an integrand so the integrand is now here this $\frac{f(z)}{z - z_0}$ this is no more analytic in that domain because the domain z_0 point is there which is enclosed by this curve C . So naturally this integrand is not analytic and we do not have this as equal to 0.

So which was the case earlier when your integrand was analytic, so here the integrand is not analytic because of this term $\frac{1}{z - z_0}$ and as a result this integral has the value $2\pi i$ and the function at z_0 , so this is what we call the Cauchy integral formula. So it has a various applications for evaluation of such integrals where the integrand is not analytic for instance. So this formula sometimes we also write in this form that $\int_C \frac{f(z)}{z - z_0} dz = 2\pi i f(z_0) + \int_C \frac{f(z) - f(z_0)}{z - z_0} dz$, so this $2\pi i$ we can bring to the right hand side and then this is an integral over this closed path of this $\frac{f(z) - f(z_0)}{z - z_0} dz$.

So going to the quick proof of this we can consider this integral here $\int_C \frac{f(z)}{z - z_0} dz$ and then we add here this term $\frac{f(z_0)}{z - z_0}$ and subtract this $\frac{f(z_0)}{z - z_0}$, so again we are with this $\frac{f(z)}{z - z_0}$ and then we can write down it as, so $\frac{f(z_0)}{z - z_0}$, the first term and here we have $\frac{1}{z - z_0}$ for the second 1 , we have this $\frac{f(z) - f(z_0)}{z - z_0}$ and then $\frac{1}{z - z_0}$, so we have broken this integral into 2 parts and then we know already the result we have seen in previous lectures that the result of this $\int_C \frac{1}{z - z_0} dz$ was $2\pi i$. So the first integral we have evaluated already its $\frac{f(z_0)}{z - z_0}$ and into $2\pi i$, the second integral over this closed curve C $\int_C \frac{f(z) - f(z_0)}{z - z_0} dz$ we will evaluate now.

(Refer Slide Time: 05:26)

$$\oint_C \frac{f(z) - f(z_0)}{z - z_0} dz$$

Since $f(z)$ is analytic and therefore continuous. Hence
 for given $\epsilon > 0$ we can find a $\delta > 0$ such that

$$|f(z) - f(z_0)| < \epsilon \text{ for all } |z - z_0| < \delta$$

Using principle of deformation

$$\oint_C \frac{f(z) - f(z_0)}{z - z_0} dz = \oint_K \frac{f(z) - f(z_0)}{z - z_0} dz$$
 K is a circle of radius ρ , $\rho < \delta$

$$\left| \frac{f(z) - f(z_0)}{z - z_0} \right| < \frac{\epsilon}{\rho}$$

$$\oint_C \frac{f(z) - f(z_0)}{z - z_0} dz$$

Since $f(z)$ is analytic and therefore continuous. Hence
 for given $\epsilon > 0$ we can find a $\delta > 0$ such that

$$|f(z) - f(z_0)| < \epsilon \text{ for all } |z - z_0| < \delta$$

Using principle of deformation

$$\oint_C \frac{f(z) - f(z_0)}{z - z_0} dz = \oint_K \frac{|f(z) - f(z_0)|}{|z - z_0|} dz$$
 K is a circle of radius ρ , $\rho < \delta$

$$\left| \frac{f(z) - f(z_0)}{z - z_0} \right| < \frac{\epsilon}{\rho} \quad \text{as } |f(z) - f(z_0)| < \epsilon \text{ and } |z - z_0| = \rho$$

So we have the situation here that this integral we want to evaluate and we consider now the situation around this z_0 , we take a circle of circle which we are calling it k here of radius ρ and the ρ is less than δ and what is the δ we will see now this connection here. So fz is analytic and therefore continuous that is ofcourse and hence for given so since this fz is continuous so we can use this definition of continuity for a complex valued function. So here for given ϵ we can always find a δ such that this difference fz minus fz_0 is less than ϵ for any z in this disc here z minus z_0 less than δ .

So this epsilon and delta are from the definition of the continuity since fz is continuous so for any given epsilon we can always find a delta such that this relation holds and now we have enclosed this points z_0 by a circle whose radius is ρ and ρ is even less than delta. So for given delta now we can choose a ρ where ρ is less than delta and we can enclose this z_0 by this circle of radius ρ .

So using now the principle of deformation, so just to recall what was the deformation that instead of taking this integral over the C we can also do that over a any other curve and then the value will be the same, this is what we have learnt before. So that integral that deformation principle says that this integral fz minus z_0 over z minus z_0 dz will be equal to fz minus z_0 over z minus z_0 , so that we have already learnt.

So while making a curve there and then we have consider this as a simply connected domain where the function, the integrand is analytic and then we have got this result which says that the integral over this closed curve C , the value of this integral will be equal to any other path we can take inside this domain and the value will be equal so that part was already discussed, so what we have observe now here that this integral is equal to this integral.

And this is going to be a simpler integral because we are talking about this k which is a circle there. So k is a circle of radius ρ and the ρ we have taken less than delta. So now we will make use of this inequality that fz minus fz_0 over z minus z_0 . So on this circle k this z minus z_0 the absolute value of this z minus z_0 the modulus of z minus z_0 is ρ , so this z minus z_0 is replace by ρ and then from the continuity of fz we have already this relation that fz minus fz_0 is less than epsilon.

So we have this inequality here that epsilon we can bound this integrand of this integral by epsilon over ρ . And now so this is already discussed that this is epsilon and we are exactly on the boundary of this case so that can be replaced just by ρ and here the upper one we have just bounded it by epsilon.

(Refer Slide Time: 09:22)

We have $\left| \frac{f(z) - f(z_0)}{z - z_0} \right| < \frac{\epsilon}{\rho}$

Using M-L inequality $\left| \int_C f(z) dz \right| \leq ML$

$$\left| \int_C \frac{f(z) - f(z_0)}{z - z_0} dz \right| < \frac{\epsilon}{\rho} \cdot 2\pi\rho = 2\pi\epsilon$$

Since, ϵ can be chosen arbitrary small, we have

$$\int_C \frac{f(z) - f(z_0)}{z - z_0} dz = 0$$

$$\int_C \frac{f(z)}{z - z_0} dz = f(z_0)2\pi i + \int_C \frac{f(z) - f(z_0)}{z - z_0} dz \Rightarrow \int_C \frac{f(z)}{z - z_0} dz = f(z_0)2\pi i$$

The slide also features a diagram of a region C in the complex plane with a point z_0 and a circle K of radius $\rho < \delta$ centered at z_0 . A small video inset of the lecturer is visible in the bottom right corner.

So with this bound we can observe that we will use this M-L inequality which was also discussed in previous lectures. So this fz the absolute value of this integral is bounded by M into the L , L is the length of the curve and M is the upper bound for this integrant, so we have already the upper one for the integrant that means this we can bound by this ϵ over ρ that is the bound for this integrant and then $2\pi\rho$ that is the circumference of this circle K , so 2π and the ρ was radius. So the arc length of the curve that is $2\pi\rho$.

So if this a simplified this is coming 2π and ϵ , so now the point is that this integral the value of this integral, the absolute value of this integral is bounded by $2\pi\epsilon$ and we should note that this ϵ was arbitrary, so from the continuity of fz we have said that for a given ϵ , so ϵ can be chosen as small as possible arbitrarily small, so what this says that if this can be chosen arbitrary small the value of this integral is going to be 0 because the value of this integral is bounded by $2\pi\epsilon$.

And we are telling that ϵ can be chosen arbitrarily small, this means that the value of the integral has to be 0 otherwise it cannot be less than this $2\pi\epsilon$ and ϵ is arbitrary number. So now from this breakup of the integral the first part already was evaluated which was $2\pi i f(z_0)$ the second we have seen that this is going to be 0, so we have this result which is the Cauchy integral theorem, that is integral value is equal to $2\pi i$ and fz_0 .

(Refer Slide Time: 11:19)

CAUCHY INTEGRAL FORMULA FOR MULTIPLY CONNECTED DOMAIN

$f(z)$ is analytic

$$f(z_0) = \frac{1}{2\pi i} \oint_{C_1} \frac{f(z)}{z - z_0} dz + \frac{1}{2\pi i} \oint_{C_2} \frac{f(z)}{z - z_0} dz$$

NPTEL

CAUCHY INTEGRAL FORMULA FOR MULTIPLY CONNECTED DOMAIN

$f(z)$ is analytic

$$f(z_0) = \frac{1}{2\pi i} \oint_{C_1} \frac{f(z)}{z - z_0} dz - \frac{1}{2\pi i} \oint_{C_2} \frac{f(z)}{z - z_0} dz$$

NPTEL

There is an extension for this for multiply connected domain because so far we have seen that the result is valid for simply connected domain, now if we have the multiply connected domain now the outer curve here is traced anticlockwise and the inner one we have taken the clockwise direction. So in that situation the results says that $f(z_0)$ is equal to the first integral over the C_1 and plus over the C_2 , we can have a many such holes there, so like this like C_1 then we have here another curve C_2 the hole in this, then we have C_3 so then we have C_4 and so on.

So we can have many such, so the for the inner circle we should have the clockwise direction to happen to for this result which is a sum of all these curve integrals, so the outer integrals should

be in the anticlockwise direction and then if the inner one are in the clockwise directions then we can have we can simply add these integrals and the value will be equal to $fz 0$. So having this I should make one more remark that what will happen if we take for instance this also in the anticlockwise direction.

If we take C_2 in anticlockwise direction then this plus sign will become minus sign and we will have this $fz 0$ equal to this and this minus $\frac{1}{2\pi}$ integral over C_2 , so that is also possible. So if we are taking the clockwise direction these two will be added otherwise we can also subtract these results.

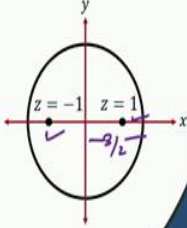

(Refer Slide Time: 13:21)

Example: Evaluate $\oint_C \frac{\tan z}{(z^2 - 1)} dz$ $C: |z| = \frac{3}{2}$

Singularities of $f(z)$: $z = 1, -1, \pm \frac{\pi}{2}, \pm \frac{3\pi}{2}, \dots$

Points $z = \pm \frac{\pi}{2}, \pm \frac{3\pi}{2}, \dots$ does not lie inside $|z| = \frac{3}{2}$

$$\oint_C \frac{\tan z}{(z^2 - 1)} dz = \oint_C \frac{\tan z}{(z-1)(z+1)} dz = \oint_C \frac{\tan z}{2} \left[\frac{1}{(z-1)} - \frac{1}{(z+1)} \right] dz$$

$$= \frac{1}{2} \oint_C \frac{\tan z}{(z-1)} dz - \frac{1}{2} \oint_C \frac{\tan z}{(z+1)} dz = \frac{1}{2} 2\pi i \tan 1 - \frac{1}{2} 2\pi i \tan(-1)$$

NPTEL

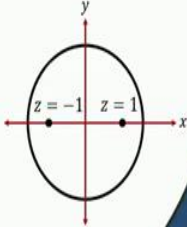

Example: Evaluate $\oint_C \frac{\tan z}{(z^2 - 1)} dz$ $C: |z| = \frac{3}{2}$

Singularities of $f(z)$: $z = 1, -1, \pm \frac{\pi}{2}, \pm \frac{3\pi}{2}, \dots$

Points $z = \pm \frac{\pi}{2}, \pm \frac{3\pi}{2}, \dots$ does not lie inside $|z| = \frac{3}{2}$

$$\oint_C \frac{\tan z}{(z^2 - 1)} dz = \oint_C \frac{\tan z}{(z-1)(z+1)} dz = \oint_C \frac{\tan z}{2} \left[\frac{1}{(z-1)} - \frac{1}{(z+1)} \right] dz$$

$$= \frac{1}{2} \oint_C \frac{\tan z}{(z-1)} dz - \frac{1}{2} \oint_C \frac{\tan z}{(z+1)} dz = \frac{1}{2} 2\pi i \tan 1 - \frac{1}{2} 2\pi i \tan(-1)$$

$$= 2\pi i \tan 1$$

NPTEL

Okay, well so we can now move for the evaluations. So we evaluate these integral $\tan z$ over z square minus 1 and then we have here z is the absolute value z is 3 by 2. So in that case we have a integrant which is matching with this integral formula, so in the denominator we have this z plus 1, z minus 1 and we should look now first the singularities of this fz the integrant fz is the integrant, so naturally the z is equal to 1, z is equal to minus 1 we have the problem in the integrant because this will go to 0 in either situation and then this π by 2, 3π by 2 and so on the \tan function will be become infinity.

So at all these points the function is not differentiable or function is not analytic at those points so we call these points as singular points of this fz of the integrant, so because we want to identify that where the function is not differentiable or not analytic otherwise if the function is analytic everywhere its straightaway we can use the Cauchy theorem and the value will be 0. So now the situation is that this π by 2 and 3π by 2 because here the radius of this circle here is 3 by 2.

So only these two points lie inside that is z is equal to minus 1 and z is equal to plus 1. the all other points like π by 2 which is π is more than 3, so 3 by 2 that is outside the domain of concern outside this C , so here this π by 2, 3π by 2 they are not at all in the domain, so not of our concern but here z is equal to minus 1 and z is equal to plus 1 these two points are inside the circle C and therefore they will be considered now as the point of where the function is not analytic.

So here now we have $\tan z$ over $z^2 - 1$ we can write $z - 1$ and $z + 1$ and then we can have this partial fraction of the two, 1 over $z - 1$, 1 over $z + 1$ and the half the first integral is $\tan z$ over minus 1 the second integral $\tan z$ over $z + 1$, so now we have exactly in the form of this Cauchy integral formula where we can directly apply the result, this is like fz over $z - 1$ and this 1 is exactly the point inside the circle here and z equal to minus 1 is also inside the circle.

So here we have the half as already there than $2\pi i$ because of the formula and \tan has to be evaluated at 1, so this \tan has to be this fz has to be evaluated at 1. Similarly for the second part we have minus half $2\pi i$ and \tan here must be evaluated at minus 1, so this is the final result that $2\pi i$ and the $\tan 1$ this is the answer of this integral which we have evaluated using the Cauchy integral formula.

(Refer Slide Time: 16:57)

DERIVATIVE OF ANALYTIC FUNCTION

If $f(z)$ is analytic in a domain D , then its derivative at any point $z = z_0$ is given by

$$\rightarrow f^{(n)}(z_0) = \frac{n!}{2\pi i} \oint_C \frac{f(z)}{(z - z_0)^{n+1}} dz \leftarrow$$

where C is a simple closed curve in D enclosing the point z_0 .

Using Cauchy-Integral formula $f(z_0) = \frac{1}{2\pi i} \oint_C \frac{f(z)}{z - z_0} dz$

$$f(z_0 + \Delta z_0) = \frac{1}{2\pi i} \oint_C \frac{f(z)}{z - z_0 - \Delta z_0} dz$$

DERIVATIVE OF ANALYTIC FUNCTION

If $f(z)$ is analytic in a domain D , then its derivative at any point $z = z_0$ is given by

$$f^{(n)}(z_0) = \frac{n!}{2\pi i} \oint_C \frac{f(z)}{(z - z_0)^{n+1}} dz$$

where C is a simple closed curve in D enclosing the point z_0 .

Using Cauchy-Integral formula $f(z_0) = \frac{1}{2\pi i} \oint_C \frac{f(z)}{z - z_0} dz$

$$f(z_0 + \Delta z_0) = \frac{1}{2\pi i} \oint_C \frac{f(z)}{z - z_0 - \Delta z_0} dz$$

$$\Rightarrow f(z_0 + \Delta z_0) - f(z_0) = \frac{1}{2\pi i} \oint_C f(z) \left[\frac{1}{z - z_0 - \Delta z_0} - \frac{1}{z - z_0} \right] dz$$

Well, so there is another one, that derivative of analytic function, the derivative of analytic functions the formula is quite similar to what we have seen as a Cauchy integral formula. So if fz is analytic in a domain D then its derivative at any point z equal to z_0 is given by this formula here that f the n th derivative at z_0 we can compute by this line integral factorial n over $2\pi i$ and we have fz over z minus z_0 power this n plus 1 and dz .

So that is has a nice applications and a very interesting fact that the derivative of this function which is analytic we can compute with the help of such integrals, such a curve integral. So here the C is an simple close curve in D enclosing the point z_0 so that is the only condition we can

take any C which encloses this z_0 point and it is this domain D where your function is analytic that is the only condition we have.

So using this Cauchy integral formula we can realize the above result, so the Cauchy integral formula says that $f(z_0)$ is $\frac{1}{2\pi i}$ and the integral $\oint_C \frac{f(z)}{z - z_0} dz$. From here we can derive its first derivative and then it can be generalized, so for the first derivative let us just make an increment here $f(z_0 + \Delta z)$ and then we will apply the fundamental theorem of differentiability.

So $f(z_0 + \Delta z)$ we have made this increment Δz naught, so $\frac{1}{2\pi i}$ the integral $\oint_C \frac{f(z)}{z - z_0} dz$ over this z is replaced with $z_0 + \Delta z$. So here instead of z_0 we will now make $z_0 + \Delta z$, so $z - z_0$ and z_0 is replaced by $z_0 + \Delta z$.

So this is the result now $f(z_0 + \Delta z) - f(z_0)$ and we can look at this difference now $f(z_0 + \Delta z) - f(z_0)$ by this integral we can have now $\frac{1}{2\pi i}$ and this $\frac{1}{(z - z_0 - \Delta z)(z - z_0)}$ and then the second one $\frac{1}{z - z_0}$.

(Refer Slide Time: 19:42)

$$\Rightarrow \frac{f(z_0 + \Delta z_0) - f(z_0)}{\Delta z_0} = \frac{1}{2\pi i} \oint_C f(z) \left[\frac{1}{z - z_0 - \Delta z_0} - \frac{1}{z - z_0} \right] dz = \frac{1}{2\pi i} \oint_C \frac{f(z)}{(z - z_0 - \Delta z_0)(z - z_0)} dz$$

$$\Rightarrow \lim_{\Delta z_0 \rightarrow 0} \frac{f(z_0 + \Delta z_0) - f(z_0)}{\Delta z_0} = \lim_{\Delta z_0 \rightarrow 0} \frac{1}{2\pi i} \oint_C \frac{f(z)}{(z - z_0 - \Delta z_0)(z - z_0)} dz = \frac{1}{2\pi i} \oint_C \frac{f(z)}{(z - z_0)^2} dz$$

$$\Rightarrow f'(z_0) = \frac{1}{2\pi i} \oint_C \frac{f(z)}{(z - z_0)^2} dz$$

Similarly, one can prove results of higher orders.

Since, z_0 is arbitrary in D , the derivative of $f(z)$ of all orders are analytic in D if $f(z)$ is analytic in D .

So we can simplify this now, these two can be simplified to have this $f(z)$ divided by this the product of the 2 taking this LCM and then we can have just 1 there, so $\frac{1}{2\pi i}$ and then we got this $\frac{f(z)}{z - z_0 - \Delta z_0} - \frac{f(z)}{z - z_0}$ and this product of this one. So now if we

take the limit as Δz approaches 0, z_0 approaches to 0 what will happen to this and that is exactly precisely the derivative of this fz at the z_0 .

So taking this limit what we will now observe here, so we have $\frac{1}{2\pi i}$ and this integral and we want to take this limit Δz approaches to 0, so what will happen when Δz approaches to 0? This is exactly becoming $z - z_0$ and $(z - z_0)^2$ we are getting and now this everything is free form Δz_0 . So we got this formula for the derivative that f' at z_0 is $\frac{1}{2\pi i} \int \frac{fz}{(z - z_0)^2}$.

Well, so this is just for the first derivative and then we can go for in a similar way we can approach for the higher order derivative which we are not doing now but we have now the idea that how this derivative is written in terms of the integral using Cauchy integral formula. So since this z_0 is arbitrary we have chosen just an arbitrary point z_0 the derivative of fz for other orders are analytic in D . So what we have seen if fz is analytic we can get this f' also at any point there in the domain.

So all order derivatives of this fz will be also analytic in D if fz is analytic in D , so that is a very interesting result in this connection of the complex variables that if this fz is analytic in D then all its derivatives will be also analytic in that domain D which is readily prove from this result where we have seen that the derivatives can be computed easily once we know that this fz is analytic.

(Refer Slide Time: 22:22)

Example: Evaluate $\oint_C \frac{e^{2z}}{(z+1)^4} dz$, $C: |z| = 3$

Let $f(z) = e^{2z}$, $z_0 = -1$, $n = 3$

$f'(z) = 2e^{2z} \Rightarrow f'(-1) = 2e^{2(-1)} = \frac{2}{e^2}$

$f''(-1) = \frac{4}{e^2}$ $f^{(3)}(-1) = \frac{8}{e^2}$

$\frac{8}{e^2} = \frac{3!}{2\pi i} \oint_C \frac{e^{2z}}{(z+1)^4} dz \Rightarrow \oint_C \frac{e^{2z}}{(z+1)^4} dz = \frac{8\pi i}{3e^2}$

Cauchy Integral Formula:
 $f^{(n)}(z_0) = \frac{n!}{2\pi i} \oint_C \frac{f(z)}{(z-z_0)^{n+1}} dz$

NPTEL

So we will now go through this example, we will evaluate here e^{2z} over $(z+1)^4$ dz and here the curve is absolute this modulus z equal to 3, so it is a circle center 0 and radius 3. Cauchy integral formula says that the third derivative we can evaluate by this factorial $3! 2\pi i$ e^{2z} and $(z+1)^4$.

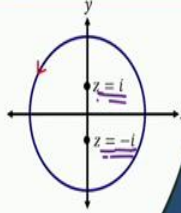

So this is exactly $(z+1)^4$ here and this is our fz . So with this formula we see connection to this integral and now we can proceed with this taking this fz as 2^z and this third derivative and we evaluate at this z naught point, so we will get exactly the result of this. So here this $z - z_0$ a power 4, so z_0 is like minus 1 and we can evaluate the derivatives. So fz is e^{2z} , z_0 is minus 1, n is 3, first derivative is 2 times e^{2z} .

Its derivative at minus 1 we can evaluate that is 2 over e^2 then the second derivative we can evaluate that is 4 over e^2 and then the third derivative we can evaluate at 8 over e^2 , so the third derivative we need for the value of this integral here and this third derivative then we can put there in the integral, so this is the third derivative and equal to factorial $3! 2\pi i$ e^{2z} over $(z+1)^4$, so this is the value of the integral then.

This factorial $3!$ over $2\pi i$ we can bring to the left hand side, so we are getting the value of the integral as $8\pi i$ over $3e^2$, so this was a direct application of the Cauchy integral formula where we can get the value of such a integral.

Example: Evaluate $\oint_C \frac{e^{zt}}{z^2+1} dz$, $C: |z|=3$.

$$\oint_C \frac{e^{zt}}{z^2+1} dz = \oint_C \frac{e^{zt}}{2i} \left[\frac{1}{z-i} - \frac{1}{z+i} \right] dt$$

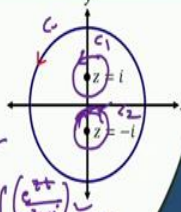

$$= \frac{1}{2i} \left[\oint_C \frac{e^{zt}}{z-i} dz - \oint_C \frac{e^{zt}}{z+i} dz \right]$$

z_0 = i *z_0 = -i*

$$= \frac{1}{2i} 2\pi i [e^{it} - e^{-it}]$$

IIT Kharagpur

Example: Evaluate $\oint_C \frac{e^{zt}}{z^2+1} dz$, $C: |z|=3$.

Method - 2

$$\oint_C \frac{e^{zt}}{z^2+1} dz = \oint_C \frac{e^{zt}}{2i} \left[\frac{1}{z-i} - \frac{1}{z+i} \right] dt$$

$$= \frac{1}{2i} \left[\oint_C \frac{e^{zt}}{z-i} dz - \oint_C \frac{e^{zt}}{z+i} dz \right]$$

$$= \frac{1}{2i} 2\pi i [e^{it} - e^{-it}]$$

$$= 2\pi i \sin t$$

Method - 1

$$\oint_C f(z) dz = \oint_{C_1} \frac{e^{zt}}{z-i} dz + \oint_{C_2} \frac{e^{zt}}{z+i} dz$$

$$= 2\pi i \left[\frac{e^{it}}{2i} + \frac{e^{-it}}{-2i} \right]$$

IIT Kharagpur

Another example, where we will evaluate e^{zt} over $z^2 + 1$ dz and here the circle is given by absolute value z modulus z equal to 3, so again we have a circle center 0 and radius 3. So if we see the singularity here $z^2 + 1$ we have $z + 1$ and z equal to i and z is equal to minus i , so at these two points the function is problematic, so we will proceed now writing this as a partial fraction as we have done in one of the earlier example.

So e^{zt} then we have $2i$ and then this is the partial fraction $2i$ will be there when we write down in terms of $z^2 + 1$, so that will cancel out. So this is the partial fraction we have for 1 over $z^2 + 1$. So now we have these 2 integrals over $z - i$ and $z + i$, in both

we can use the Cauchy integral formula. Here the z naught is i and here z naught is $-i$, so z naught is $-i$, so in both we can use the Cauchy integral formula and that says that $2\pi i$ and the value of the function e^{zt} and that means z is i here and the here z is $-i$.

So we got this formula which can be also written in terms of the sign function, so $2\pi i$ and then $e^{it} - e^{-it}$ over $2i$ we can write down as $\sin t$. So this was the one approach for instance we have proceed where we have applied this formula the integral formula to get this $2\pi i$ and $\sin t$. The another approach could be that we can think of as we can take two more circles that enclosed these 2 points, z is equal to $iz - i$, so let us call it as C_1 and the another curve here we can call it as C_2 .

So these two curves C_1 and C_2 and the outer one was the given one the C_1 , so we have drawn 2 more circles C_1 and C_2 enclosing these 2 problematic points and then we can write down using this extension for the multiply connected domain that this C the given integral the fz I am talking about the fz is the whole integrant, so this is whole integrant here fz at present. So I can write down that this integral over C will be integral over the C_1 and plus C_2 and doing this setting now.

So over C_1 what I will do, when I do over C_1 I will take a $z - i$ and the rest I will write down e^{zt} divided by $z + i$, because now this numerator is analytic and here $z - i$ is exactly fitting into the formula of the Cauchy integral. So plus when I do the integral over the C_2 what I will do now e^{zt} and I will take here $z - i$ as my function which is analytic and here I will do this $z + i$ and then I have here dz .

So this is another approach, so this method 2 which where we do not have to use for example the partial fractions, we can just write down the given integrant in this form, e^{zt} over $z + i$ and $z - i$ and in this for the second curve we can use $z + i$. So this is the for multiply connected domain we seen the integral formula and that idea we have applied here, so then in the first case what we have? This is has to be evaluated, so $2\pi i$ and the numerator will be evaluated e^{zt} , so z is i now, so $i t$ and then divide by $z + i$, so $i + 2i$ and then again here $2\pi i$ will come.

So e power minus i t and minus 2i, so this again can be just written as 2 pi i and sin t, so this is another approach where we can avoid doing this partial fractions, so directly we can compute this partial fraction without computing partial fractions we can use the Cauchy integral formula.

(Refer Slide Time: 29:48)

Example: Evaluate $\oint_C \frac{\sin^6 z}{(z - \frac{\pi}{6})^3} dz$, $C: |z| = 1$

Let $f(z) = \sin^6 z$, $z_0 = \frac{\pi}{6}$, $n = 2$

Cauchy integral formula $\oint_C \frac{f(z)}{(z - z_0)^{n+1}} dz = \frac{2\pi i}{n!} f^{(n)}(z_0)$

$\oint_C \frac{\sin^6 z}{(z - \frac{\pi}{6})^3} dz = \frac{2\pi i}{2!} f^{(2)}(\frac{\pi}{6})$

Note that $f'(z) = 6 \sin^5 z \cos z$

$f''(z) = 30 \sin^4 z \cos^2 z + 6 \sin^5 z \cdot (-\sin z)$

$f''(\frac{\pi}{6}) = 30 \cdot \frac{1}{16} \cdot \frac{3}{4} - 6 \cdot \frac{1}{32} \cdot \frac{1}{2} = \frac{21}{16}$

$\Rightarrow \oint_C \frac{\sin^6 z}{(z - \frac{\pi}{6})^3} dz = \pi i \frac{21}{16}$

The slide also features a diagram of a unit circle in the complex plane with a point $z = \frac{\pi}{6}$ marked on the real axis. A small video inset of the lecturer is visible in the bottom right corner.

So another example where we have sin 6z and z minus pi power 3, so here we can use, so here sin z is sin 6z and we will apply exactly the Cauchy integral formula which is the extension to the derivatives. So z0 here pi by 6 and n we will take 2, so that here we are getting exactly 3 and plus 3, so this was the Cauchy integral formula, here 2 plus 1 if it is 2 here the derivative is second derivative.

So this is fitting exactly to the given integral we can compute with this computation of the second order derivative. So f prime z is already with sin 6z we have computed here and we can do this computations once again for the second derivative and we can evaluate this at pi by 6, so the value is coming 21 by 16. So here if we write 21 by 16 this is the value of the given integral using this derivative formula of the Cauchy integral.

(Refer Slide Time: 30:56)

Example: Evaluate $\oint_C \frac{3z^2 + z}{z^2 - 1} dz$, $C: |z - 1| = 1$

Singularities of integrand: $z^2 - 1 = 0 \Rightarrow z = \pm 1$

$\oint_C \frac{3z^2 + z}{(z - 1)(z + 1)} dz = \frac{1}{2} \oint_C \frac{3z^2 + z}{z - 1} dz + \frac{1}{2} \oint_C \frac{3z^2 + z}{z + 1} dz$

\Rightarrow Cauchy integral formula Cauchy theorem

$= \frac{1}{2} \cdot 2\pi i (3 + 1) + 0$

$= 4\pi i$

Handwritten notes: "analytic in C and inside C", "analytic", " $\oint \frac{3z^2 + z}{z + 1} dz = 0$ ", " $= 2\pi i \cdot \frac{4}{2}$ ".

So the last example where we have again the similar situation the z square minus 1 is coming and this is with center at 1 0 and then the radius is 1. So singularities again here we have z plus minus 1, so the minus 1 is outside this circle at center 1 and then the radius 1. So we have only 1 singularity which is coming inside this, z is equal to minus 1 is outside so that is not in the picture. So what we can do, the first approach could be that we can break again into the partial fractions and then the each integral can be evaluated.

Indeed the second integral here where we have z plus 1, so the integrand here is analytic because z is equal to minus 1 is outside the domain, so here this is analytic, analytic in C and inside C , on C and inside C . So this is analytic and the Cauchy integral theorem can be used here to and the first one we have use the Cauchy integral formula and second one we can use the Cauchy theorem, so which says that this plus this 0 and the total answer we have $2\pi i$.

Or another approach it could be that the given integral, so the second approach could be that the given integral we can write as $3z^2 + z$ over this z plus 1 all together and then we can replace z minus 1 and then dz . If we consider this integral now, so this will be our function hence divided by z minus 1 because this is now analytic in our domain, so no problem and then we can apply exactly the formula $2\pi i$ and this has to be evaluated over z is equal to 1.

So here we have the 4 over and then 1 that means 2 2, so this 2 2 gets cancel and we have $4\pi i$, so this could be the another approach where we do not have to do this partial fraction

unnecessarily, we can just simply rewrite our integrand so that the numerator everything is analytic and this z is equal to 1 was the problematic point, so we have divided by the z minus 1 and we can evaluate this.

CONCLUSION

Cauchy Integral Formula $f(z_0) = \frac{1}{2\pi i} \oint_C \frac{f(z)}{z - z_0} dz$

Derivative Formula $f^{(n)}(z_0) = \frac{n!}{2\pi i} \oint_C \frac{f(z)}{(z - z_0)^{n+1}} dz$

Just to conclude now, so we have learnt about the Cauchy integral formula which is a very useful for evaluating the integrals and we have also seen the derivative formula which is exactly the

kind of extension of this or we can say this is particular case let us say when we put n equal to 0 because putting n equal to 0, n factorial 0 if we take 1 we are exactly getting this formula.

So this is a particular case of this more general derivative formula and here we call it Cauchy integral formula, not the Cauchy integral theorem, the Cauchy integral theorem was when the integral was 0 and the integrand was analytic. So with this.
