Lecture 18
Laurent's Series

So welcome back to lectures on Engineering Mathematics 2. So, this is lecture number 18 and we will be talking about Laurent Series, which is a generalized version of the Taylor series which we have discussed in the previous lecture.

(Refer Slide Time: 00:26)

So, today we will cover what is the Laurent Series and then the practical methods for obtaining Laurent series quite similar to what we have done for the Taylor series.

(Refer Slide Time: 00:40)

The slide is titled "TAYLOR'S SERIES". It contains the following text and diagram:

Suppose that f is analytic in $|z - z_0| < R_0$. Then $f(z)$ has the power series representation

$$f(z) = f(z_0) + f'(z_0)(z - z_0) + \dots + \frac{f^{(n)}(z_0)}{n!}(z - z_0)^n + \dots$$

The Taylor series converges to $f(z)$ for z that lies in the disk $|z - z_0| < R_0$.

The series converges to $f(z)$ within the circle about z_0 whose radius is the distance from z_0 to the nearest point z_1 at which f fails to be analytic

The diagram shows a complex plane with a point z_0 and a point z_1 . A circle of radius R_0 is drawn around z_0 , extending to z_1 . Handwritten blue circles highlight the expression $|z - z_0| < R_0$ in the text and the disk in the diagram.

At the bottom right of the slide, there is a small video inset of Professor Jitendra Kumar. The slide footer includes the IIT Kharagpur and NPTEL logos.

So, the Taylor Series just to recall suppose that f is analytic in this region z minus z_0 less than R naught so in this disc with radius R naught and this center z_0 then $f(z)$ has the power series representation this is what we have discussed. So, if f is analytic in this in this disc here with center z_0 and radius R naught in that case $f(z)$ can be represented by such a series expansion $f(z)$ naught the first derivatives z minus z_0 and the n th derivative and so on.

And we have also discussed that the Taylor series converges to $f(z)$ for z that lies in this disk. So, a z minus z_0 less than R naught, if this $f(z)$ is analytic in this disk, then the series will converge to $f(z)$ for any z that lies in this disk.

(Refer Slide Time: 01:57)

TAYLOR'S SERIES

Suppose that f is analytic in $|z - z_0| < R_0$. Then $f(z)$ has the power series representation

$$f(z) = f(z_0) + f'(z_0)(z - z_0) + \dots + \frac{f^{(n)}(z_0)}{n!} (z - z_0)^n + \dots$$

The Taylor series converges to $f(z)$ for z that lies in the disk $|z - z_0| < R_0$

The series converges to $f(z)$ within the circle about z_0 whose radius is the distance from z_0 to the nearest point z_1 at which f fails to be analytic

DT Khurana
NPTEL

So, and we have also discussed that the Taylor series $f(z)$ that the series which we calling Taylor series converges to $f(z)$ and within the circle about z_0 and the maximum radius of this circle we can go up to the nearest point. So here its visualize there up to the nearest point where f fails to be analytic.

So, if this $f(z)$ is analytic in this disk here, we can go on increasing the radius until we meet the point where $f(z)$ is naught analytic or $f(z)$ fails to be analytics. So, that is what we have discussed in the previous lecture. So, the most important here to note that, that this $f(z)$ is analytic in the whole disc of radius R naught and then we can represent this $f(z)$ by such a series representation which is called Taylor series representation and the maximum radius where this series will converge to $f(z)$ can be obtained by extending this radius until we meet the point where $f(z)$ fails to be analytic.

So, this was the summary of the last previous lecture and now, we will go for the further extension or the generalization because very often we will see that some functions they are not analytic at some point or in some region. So, what kind of representation we can have for those functions.

(Refer Slide Time: 03:33)

In many applications we encounter functions that are **not analytic** at some points, or in some region of the complex plane and consequently **Taylor's series** cannot be employed in the neighborhood of such points.

However, another series representation, called **Laurent series**, can be found in which both positive and negative powers of $(z - z_0)$ exists.

Such series are valid for functions that are analytic in a circular annulus $R_1 < |z - z_0| < R_2$.

The diagram shows a complex plane with a point z_0 at the center. Two concentric circles are drawn around z_0 , with radii R_1 and R_2 . The region between these two circles is shaded and labeled as the circular annulus. A small inset image of a man is visible in the bottom right corner of the slide.

So, as written here, so in many applications we encounter functions that are not analytic at some points if they are analytic we have seen we can represent by this Taylor series representation, but if they are not analytic if the function is not analytic at some points or in some region of the complex plane and then this Taylor series cannot be written in the neighborhood of such points when we have the function which is not analytic at a certain point or a region.

In that case the another series which is called Laurent series that can be found and this Laurent series contains the positive power of z minus z_0 and also the negative power of z minus z_0 . And this is what we will discuss today and we will also discuss that how to obtain such a series.

So, this Laurent series, they are valid for the functions that are analytic in the circular annulus. So, it is as discussed earlier, the Taylor series can be employed when you have the function which is analytic over the whole disk. But now, we are talking about that this more generalized power series which is called Laurent series can be written for the function which are analytic here on this annulus which contains these two circles that there is a cut here with

this R one circle which is not a part of this domain now, and then we have the upper circle which is bounded whose radius is R_2 .

So, in this annulus if our function is analytic we can have a power series representation but we too, but this power series representation will contain positive power as well as negative power. Whereas, in Taylor series we have seen that only the positive powers of z minus z_0 appears, but we will observe in Laurent series both positive and negative powers will appear.

(Refer Slide Time: 05:47)

LAURENT SERIES

A function $f(z)$ analytic in an annulus

$$R_1 < |z - z_0| < R_2$$

may be represented by the

$$f(z) = \sum_{n=-\infty}^{\infty} c_n (z - z_0)^n \quad \text{where} \quad c_n = \frac{1}{2\pi i} \oint_C \frac{f(z)}{(z - z_0)^{n+1}} dz$$

C is any simple closed curve in the region of analytical enclosing the inner boundary $|z - z_0| = R_1$.

The coefficient of the term, $\frac{1}{z - z_0}$ which is c_{-1} in our notation is called the **residue** of the function $f(z)$. The **negative powers** of the Laurent's series are referred to as the **Principal Part of $f(z)$** .

So, what is the Laurent series? So, suppose this function is analytic in this annulus which is bounded by these two circles here R_1 in whose radius R_1 and R_2 . So, this can be represented then this function can be represented by this power series representation $C_n z$ minus z_0 power n and then n is now from minus infinity to plus infinity. In the Taylor series it was from 0 to infinity.

So, now we have added from minus infinity to this minus 1 these terms and similar to the Taylor series this C_n , this coefficient can be written can be represented by this integral which comes to be the derivative of f basically. So, and the C here in this integral C is any simple close curve in this region of analytical and closing the inner boundary. So, we have this region where the function is analytics, so we can take any circle which is given here, so you can take any circle which enclosed the inner boundary and of course lies in this domain where the function is analytic.

So, we can do this integration on any curve, and then this fz can be written as with the help of this power series representation. So, again this proof of this series representation is quite

involved and we are not talking about how to get exactly this power series representation. But now the coefficient term here of z minus z_0 , which is C minus 1 in our notation, the coefficient of 1 over z minus z_0 is called the residue and that there will be one more lecture we will be talking about many applications or of the residue and what is the residue theorem which relates to the integral evaluation.

And the negative powers of this Laurent series are referred to as principal part of fz so this two more terminology here the residue is the coefficient of this 1 over z minus z_0 in this Laurent series expansion and all the terms which of the Laurent series which are having negative powers, we call the principal part of fz and we will be talking about that what we can do about this principle part or what is the importance of the residue in following lectures.

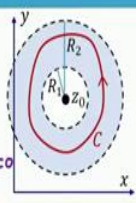

(Refer Slide Time: 08:30)

LAURENT SERIES $f(z) = \sum_{n=-\infty}^{\infty} c_n(z-z_0)^n$ $c_n = \frac{1}{2\pi i} \oint_C \frac{f(z)}{(z-z_0)^{n+1}} dz$

REMARKS

1. Suppose $f(z)$ is analytic everywhere inside the circle $|z - z_0| = R_1$. Then by Cauchy's theorem

$c_n = 0$ for $n \leq -1$.

Handwritten notes: $\sum_{n=0}^{\infty} c_n(z-z_0)^n$, $\oint_C f(z) dz = 0$, $\oint_C (z-z_0)^m f(z) dz = 0$

NPTEL IIT Kharyapur

LAURENT SERIES $f(z) = \sum_{n=-\infty}^{\infty} c_n(z-z_0)^n$ $c_n = \frac{1}{2\pi i} \oint_C \frac{f(z)}{(z-z_0)^{n+1}} dz$

REMARKS

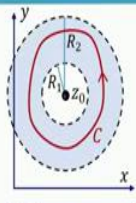

1. Suppose $f(z)$ is analytic everywhere inside the circle $|z - z_0| = R_1$. Then by Cauchy's theorem

$c_n = 0$ for $n \leq -1$. In this case, Laurent's series reduces to the Taylor's series

$$f(z) = \sum_{n=0}^{\infty} c_n(z-z_0)^n$$

2. Suppose f fails to be analytic at z_0 but is analytic in the disk $|z - z_0| < R_2$.

Then the series is valid in the punctured disk $0 < |z - z_0| < R_2$.

NPTEL IIT Kharyapur

So, we have the Laurent series expansion where C_n can be evaluated by this integral and now few remarks related to these Laurent series expansion the first one suppose this fz is analytic everywhere inside this circle of radius this $R > 1$. So, what we have observed while writing this Laurent series that our function is not analytic in this region or at some points in this region of this inner circle.

So, now we assume that our function is analytic everywhere. So, there is no such cut out of this region. So, the function is analytic. So, what will happen to this Laurent series In that case, we know from the previous lecture that when the function is analytic everywhere in this region, then we can write down the Taylor series expansion.

But the same expansion we should be able to deduce from the Laurent series because this is a bit more generalized version of the Taylor series. So, here we now we will see that indeed we can get the Taylor series also from this Laurent series. So, if the fz is analytic everywhere inside this circle also whose radius is $R > 1$ and the center is $z = 1$. So, then by the Cauchy theorem, what we know that the all the C_n these coefficients of $z - z_0$ power n all the C_n for whenever n is less than or equal to minus 1.

So, what will happen? Why the C_n is 0. So, just consider this was our C_n . So, we have $\frac{1}{2\pi i}$ and then the integral is over fz and then this $z - z_0$ and power is $n + 1$. So, if we consider this integral here, and this power the n is less than minus 1, then this power will be a negative number or 0. So either there will be a 0 power that means the integral will reduce. So in case n is minus 1, the integral will be $fz dz$ and when the power is less than minus 1 that is minus 2 or minus 3.

So we will have something $z - z_0$ power some positive power m and $fz dz$ then we will have the situation in either case since this fz is analytic and C is a close curve, this is going to be 0. And again here the same argument fz is analytic and here $z - z_0$ power positive. So, again this integrant is analytic and Cauchy theorem says that this value will be also 0.

So, all the C_n for n less than or equal to minus 1 will be 0. So, this summation will reduce to n equal to 0 to infinity and then we have C_n and $z - z_0$ power n , so this is simply the Taylor series which we have already discussed.

So, that is the first remark that if fz is analytic everywhere inside the inner circle as well. And then by the Cauchy theorem we have seen that all these C_n that means the all the negative powers of this z minus z_0 all these terms will disappear and we will get the Taylor series.

So, in this case the Laurent series reduces to the Taylor series and therefore, we are calling that this is a more generalized version of the Taylor series. Well, the second one suppose f fails to be analytic only at z_0 point, but is analytic in the in this disk of the outer radius this R_2 outer circle whose radius is R_2 .

So, suppose the function is only failing to be analytic at a point z_0 so, at the center here that z_0 the function is not analytic otherwise it is analytic everywhere inside this outer radius this whose outer circle whose radius is R_0 so, except this 1 point z_0 the function is analytic.

So, again we cannot write of course, the Taylor series because there is a point where function is not analytic, but what we now can reduce the inner the radius of the inner circle to tending to 0, because now the only point where the function is not analytic is z_0 only. So, this R_1 can be reduced to our wish now, we can go actually to 0.

So, what is the validity reason now, for this expansion is this puncture disk what we call only the 0 is excluded. So, $0 < |z - z_0| < R_2$ and then less than R_2 . So, this is the so called the puncture disk only this z_0 is avoided. Otherwise at any point we can represent the function fz by that expansion the Laurent Series expansion well.

(Refer Slide Time: 14:03)

Example: Expand $\frac{1}{1-z}$. (a) In non-negative powers of z (b) In the negative powers of z

(a) $\frac{1}{1-z} = \sum_{n=0}^{\infty} z^n$ ($|z| < 1$)

(b) $\frac{1}{1-z} = \frac{1}{-z(1-\frac{1}{z})} = -\frac{1}{z} \sum_{n=0}^{\infty} \frac{1}{z^n} = -\sum_{n=0}^{\infty} \frac{1}{z^{n+1}}$ For $|\frac{1}{z}| < 1 \Rightarrow |z| > 1$

Example: Find the Laurent's series of $f(z) = \frac{1}{1+z}$ for $|z| > 1$

$\frac{1}{1+z} = \frac{1}{z(1+\frac{1}{z})} = \frac{1}{z} \left[\sum_{n=0}^{\infty} (-1)^n \left(\frac{1}{z}\right)^n \right]$

So, now we will come to the expansion that how to how to expand a function, which is not analytic at some point in the domain using this Laurent series. So, here also we will adopt the practical approach of writing this series because getting to this integral for computing coefficient C_n that could be very complicated. So, there are the ways which many functions can be treated using the expansion of this very fundamental function 1 over 1 minus z which we have already observed in the Taylor series.

So, firstly we will see that to expand in non negative powers of z and in the negative powers of z , so these two extreme expansions we will see for this function and then various combinations we can observe for any for many other functions with the help of this example. So, here are the non negative power of z naught and the negative power of z naught. So, in one we will get just the Taylor series expansion which we have seen before and in the other

all the negative powers will come, so only the principal part there will be no positive power of z .

So, how to get these expansions the first one we have already observed before that this $1/(1-z)$ can be represented by this summation which goes from 0 to infinity and z^n and remember that the validity region for this was this, this disc of radius 1 and center 0.

Now, the second case with which you will observe and indeed we can just reformulate out of the previous one. So here if we take this $1/(1-z)$ common then we have $1/(1-z)$ as similar expansion which we have written earlier for $1/(1-z)$. So, instead of z we have this $1/z$ term now, so we can do expand again using the earlier expansion, but the validity region will change because it was $|z| < 1$ and now it will be in this new case $1/z$ in the modulus less than 1 that means, $1/|z| < 1$ which says that $|z| > 1$.

So, now this expansion the new expansion will be valid in this outer part of the disk, where $|z| > 1$ whereas, the earlier expansion this from 0 to infinity z^n is valid when $|z| < 1$. So, if we expand now this we have $1/z$ sitting outside before and then we have the summation from 0 to infinity $1/z^n$ and the validity will be $|z| > 1$ which we can evaluate from this absolute value $1/|z| < 1$.

So, we have two expansions for this $1/(1-z)$, 1 which we have seen earlier, which is the so called the Taylor series expansion valid in this $|z| < 1$ and we have another one which has only the negative power, negative powers of this z and this expansion is valid for $|z| > 1$. So, with these two extreme extension and one more example, we will see now we will be able to write down for many other functions we will see.

So, the another one we will observe here for $1/(1+z)$ but which is very similar to what we have done just now. And this we will just write for $|z| > 1$ because for $|z| < 1$ again, we know from the previous lecture that was the Taylor series expansion. So, here $1/(1+z)$ we can again use the same trick, we take z common and then we have this $1/(1+z)$.

So, again we can expand now, this $1/(1+z)$ using the Taylor series expansion, but the validity region will be computed from the absolute value of $1/|1+z| < 1$ and which will come out to be $|z| > 1$. So, here we can write down this expansion from the

previous lecture. So this minus 1 power n will be extra term and 1 over z power n, n goes from 0 to infinity.

(Refer Slide Time: 18:37)

Example: Expand $\frac{1}{1-z}$. (a) In non-negative powers of z (b) In the negative powers of z

(a) $\frac{1}{1-z} = \sum_{n=0}^{\infty} z^n \quad (|z| < 1)$

(b) $\frac{1}{1-z} = \frac{1}{-z(1-\frac{1}{z})} = -\frac{1}{z} \sum_{n=0}^{\infty} \frac{1}{z^{n+1}} = -\sum_{n=0}^{\infty} \frac{1}{z^{n+1}} \quad \text{For } \left|\frac{1}{z}\right| < 1 \Rightarrow |z| > 1$

Example: Find the Laurent's series of $f(z) = \frac{1}{1+z}$ for $|z| > 1$

$\frac{1}{1+z} = \frac{1}{z(1+\frac{1}{z})} = \frac{1}{z} \left[\sum_{n=0}^{\infty} (-1)^n \left(\frac{1}{z}\right)^n \right]$

$\frac{1}{1+z} = \sum_{n=0}^{\infty} (-1)^n z^{-n-1}$

DT Khosla
NPTEL

Well, so we have here this expansion and this is valid for mod z greater than 1. So what we have observe now we have basically the four expansions was one is for 1 have over 1 minus z valid for this mod z less than 1, we have the another expansion for 1 over 1 minus z which is given here by this series, but validities mod z greater than 1, the another one we have 1 over 1 plus z valid in this mod z greater than 1.

And we have also the Taylor series expansion 1 over 1 plus z which is simply n 0 to infinity and minus 1 power n and z power n which is valid here for mod z less than 1. So, these four these four expansions will be used now, for representing many functions in terms of the Laurent series expansion.

(Refer Slide Time: 19:44)

Example: Find all Taylor's and Laurent's series of $f(z) = \frac{-2z+3}{z^2-3z+2}$ with center $z=0$.

Partial Fraction Decomposition: $f(z) = \frac{1}{z-1} - \frac{1}{z-2}$

$-\frac{1}{z-2} = \frac{1}{2(1-\frac{z}{2})} = \frac{1}{2} \sum_{n=0}^{\infty} \frac{z^n}{2^n} = \sum_{n=0}^{\infty} \frac{z^n}{2^{n+1}}$ valid in $|z| < 2$

$\frac{|z|}{2} < 1 \Rightarrow |z| < 2$

Example: Find all Taylor's and Laurent's series of $f(z) = \frac{-2z+3}{z^2-3z+2}$ with center $z=0$.

Partial Fraction Decomposition: $f(z) = -\frac{1}{z-1} + \frac{1}{z-2}$

$-\frac{1}{z-2} = \frac{1}{2(1-\frac{z}{2})} = \frac{1}{2} \sum_{n=0}^{\infty} \frac{z^n}{2^n} = \sum_{n=0}^{\infty} \frac{z^n}{2^{n+1}}$ valid in $|z| < 2$

$-\frac{1}{z-2} = -\frac{1}{z(1-\frac{2}{z})} = -\frac{1}{z} \sum_{n=0}^{\infty} \frac{2^n}{z^n}$ valid in $\frac{2}{|z|} < 1$ or $|z| > 2$

Coming back to this example, now we want to find all Taylor's and Laurent series expansion for this function, the function is given by minus 2 z plus 3 divided by z square minus 3 z plus 2 and the center here we want to take z equal to 0 that means, we want to have the power of the z positive and negative in case of the Laurent series and only positive power of z for the Taylor series, so all possible basically expansions we are going to look now for this function and we will provide according accordingly there validity region.

So, this is the trick which was used already in the previous lecture the partial fraction decomposition we have to decompose the given function in these simple functions whose expansion is known to us. So 1 over z minus 1 and minus 1 over z minus 2. So, this we know already the possible expansion for 1 over 1 minus z or z minus 1 but we want to see now what are the possible expansion for 1 over z minus 2.

So, the one way would be that we take minus 2 common that means this minus minus plus we have 2 1 minus z by 2, and that can be expanded in this z power n over 2 power n and the validity region will be z by 2 absolute value less than 1. So, here we have this expansion the validity mod z less than 2 which is coming by this relation, the modulus z by 2 less than 1 which says mod z less than 2.

So, this series here is valid for mod z less than 2. The another possibility we instead of taking this 2 common we can take the z common so, we have z there, and then we have again 1 minus, instead of z now we have 2 over z and we can again do the write this expansion, so we have minus 1 over z and then the expansion of 1 over 1 minus 2 over z which is 2 over z power n and the validity will be coming from this 2 over z less than 1.

So, the validity here for this expansion is going to be mod z greater than 2. So, we have seen these two expansions, one is valid here for mod z less than 2 another one is valid for mod z greater than 2 we have all possible expansions for 1 of these terms in the partial fractions.

(Refer Slide Time: 22:35)

$$\Rightarrow f(z) = \frac{1}{1-z} - \frac{1}{z-2}$$

$$-\frac{1}{z-2} = \sum_{n=0}^{\infty} \frac{z^n}{2^{n+1}} \quad \text{valid in } |z| < 2$$

$$= -\frac{1}{z} \sum_{n=0}^{\infty} \frac{2^n}{z^n} \quad \text{valid in } |z| > 2$$

$$\frac{1}{1-z} = \sum_{n=0}^{\infty} z^n \quad (|z| < 1)$$

$$= -\sum_{n=0}^{\infty} \frac{1}{z^{n+1}} \quad (|z| > 1)$$

NPTEL
 IIT Kharagpur

Well, so we have this function after this partial fractions and the possible expansions. So, for 1 over z minus 2 we have just seen before. So, we have these 2 possible expansions and for 1 over 1 minus z we have already seen in the first examples, so one is valid in mod z less than 1 another one is valid for a mod z greater than 1. So, all these possible expansions we have written here.

(Refer Slide Time: 23:14)

$$f(z) = \frac{1}{1-z} - \frac{1}{z-2}$$

Case 1. For $|z| < 1$ $f(z) = \sum_{n=0}^{\infty} z^n + \sum_{n=0}^{\infty} \frac{z^n}{2^{n+1}}$

$$-\frac{1}{z-2} = \sum_{n=0}^{\infty} \frac{z^n}{2^{n+1}} \quad \text{valid in } |z| < 2$$

$$= -\frac{1}{z} \sum_{n=0}^{\infty} z^n \quad \text{valid in } |z| > 2$$

$$\frac{1}{1-z} = \sum_{n=0}^{\infty} z^n \quad |z| < 1$$

$$= -\sum_{n=0}^{\infty} \frac{1}{z^{n+1}} \quad |z| > 1$$

And now we can expand this given function using these expansions of the simple functions. So, the case 1, we will take when the mod z is less than when mod z is less than 1 in this region we will see that what will happen to the expansion. So, when mod z that is less than 1 the first function 1 over 1 minus z, so 1 over 1 minus z for mod z less than 1, we have this expansion, which is written already there. So, n 0 to infinity is z power n for the second one, for minus 1 over z minus 2 in this region mod z less than 1.

So, we have this valid series which is valid in this mod z less than 2 naturally that is also valid for mod z less than 1. So, we can use this expansion for the second term the z power n to power n plus 1. So this is valid for mod z less than 1 this is valid indeed for mod z less than 2, but as a whole this will be valid definitely for mod z less than 1 because both are valid in mod z less than 1. So, that is the trick we have used.

(Refer Slide Time: 26:29)

$$f(z) = \frac{1}{1-z} - \frac{1}{z-2}$$

$$-\frac{1}{z-2} = \sum_{n=0}^{\infty} \frac{z^n}{2^{n+1}} \quad \text{valid in } |z| < 2$$

$$= -\frac{1}{z} \sum_{n=0}^{\infty} \frac{2^n}{z^n} \quad \text{valid in } |z| > 2$$

Case I: For $|z| < 1$ $f(z) = \sum_{n=0}^{\infty} z^n + \sum_{n=0}^{\infty} \frac{z^n}{2^{n+1}} = \sum_{n=0}^{\infty} \left(1 + \frac{1}{2^{n+1}}\right) z^n$

Case II: For $1 < |z| < 2$

$$\frac{1}{1-z} = \sum_{n=0}^{\infty} z^n \quad |z| < 1$$

$$= -\sum_{n=0}^{\infty} \frac{1}{z^{n+1}} \quad |z| > 1$$

$$f(z) = \frac{1}{1-z} - \frac{1}{z-2}$$

$$-\frac{1}{z-2} = \sum_{n=0}^{\infty} \frac{z^n}{2^{n+1}} \quad \text{valid in } |z| < 2$$

$$= -\frac{1}{z} \sum_{n=0}^{\infty} \frac{2^n}{z^n} \quad \text{valid in } |z| > 2$$

Case I: For $|z| < 1$ $f(z) = \sum_{n=0}^{\infty} z^n + \sum_{n=0}^{\infty} \frac{z^n}{2^{n+1}} = \sum_{n=0}^{\infty} \left(1 + \frac{1}{2^{n+1}}\right) z^n$

Taylor Series

Case II: For $1 < |z| < 2$

$$\frac{1}{1-z} = \sum_{n=0}^{\infty} z^n \quad |z| < 1$$

$$= -\sum_{n=0}^{\infty} \frac{1}{z^{n+1}} \quad |z| > 1$$

So, now we have one expansion, which is valid for mod z less than 1, this we can we can combine just to have this form. The second region we will consider. So, first we know that some mod z less than 1, the function the given function, which is given here 1 over 1 minus z and minus z minus 2. So, this is analytic in this domain with center 0 and this radius 1.

So, the function is analytic here the first point where the analyticity breakdown z equal to 1. So, in mod z less than 1 the function is analytic and hence we have the Taylor series expansion. This is the Taylor series expansion, Taylor series. So, we have the Taylor series expansion because the function was analytic in that disc.

(Refer Slide Time: 25:31)

$$f(z) = \frac{1}{1-z} - \frac{1}{z-2}$$

$$-\frac{1}{z-2} = \sum_{n=0}^{\infty} \frac{z^n}{2^{n+1}} \quad \text{valid in } |z| < 2$$

$$= -\frac{1}{z} \sum_{n=0}^{\infty} \frac{2^n}{z^n} \quad \text{valid in } |z| > 2$$

Case I: For $|z| < 1$ $f(z) = \sum_{n=0}^{\infty} z^n + \sum_{n=0}^{\infty} \frac{z^n}{2^{n+1}} = \sum_{n=0}^{\infty} \left(1 + \frac{1}{2^{n+1}}\right) z^n$

Case II: For $1 < |z| < 2$

$$f(z) = -\sum_{n=0}^{\infty} \frac{1}{z^{n+1}} + \sum_{n=0}^{\infty} \frac{1}{2^{n+1}} z^n$$

$$\frac{1}{1-z} = \sum_{n=0}^{\infty} z^n \quad |z| < 1$$

$$= -\sum_{n=0}^{\infty} \frac{1}{z^{n+1}} \quad |z| > 1$$

The second region now, this is the annulus we have taken mod z greater than 1 and less than 2 in this case, we will now from the first function 1 over 1 minus z 1 over 1 minus z we are now talking about mod z greater than 1. So, this is the valid expansion which we will take now with minus sign 1 over z n plus 1 and the second one we are going up to this mod z less than 2.

So, again this first one here valid mod z less than 2, we will use that expansion here and then we have this as a valid expansion in this region because the both the series are valid in the given domain.

(Refer Slide Time: 26:23)

$$f(z) = \frac{1}{1-z} - \frac{1}{z-2}$$

$$-\frac{1}{z-2} = \sum_{n=0}^{\infty} \frac{z^n}{2^{n+1}} \quad \text{valid in } |z| < 2$$

$$= -\frac{1}{z} \sum_{n=0}^{\infty} \frac{2^n}{z^n} \quad \text{valid in } |z| > 2$$

Case I: For $|z| < 1$ $f(z) = \sum_{n=0}^{\infty} z^n + \sum_{n=0}^{\infty} \frac{z^n}{2^{n+1}} = \sum_{n=0}^{\infty} \left(1 + \frac{1}{2^{n+1}}\right) z^n$

Case II: For $1 < |z| < 2$

$$f(z) = -\sum_{n=0}^{\infty} \frac{1}{z^{n+1}} + \sum_{n=0}^{\infty} \frac{1}{2^{n+1}} z^n$$

$$\frac{1}{1-z} = \sum_{n=0}^{\infty} z^n \quad |z| < 1$$

$$= -\sum_{n=0}^{\infty} \frac{1}{z^{n+1}} \quad |z| > 1$$

Case III: For $|z| > 2$ $f(z) = -\sum_{n=0}^{\infty} \frac{1}{z^{n+1}} - \sum_{n=0}^{\infty} \frac{2^n}{z^{n+1}}$

$f(z) = \frac{1}{1-z} - \frac{1}{z-2}$

Case I: For $|z| < 1$ $f(z) = \sum_{n=0}^{\infty} z^n + \sum_{n=0}^{\infty} \frac{z^n}{2^{n+1}} = \sum_{n=0}^{\infty} \left(1 + \frac{1}{2^{n+1}}\right) z^n$

Case II: For $1 < |z| < 2$

$f(z) = -\sum_{n=0}^{\infty} \frac{1}{z^{n+1}} + \sum_{n=0}^{\infty} \frac{1}{2^{n+1}} z^n$

Case III: For $|z| > 2$ $f(z) = -\sum_{n=0}^{\infty} \frac{1}{z^{n+1}} - \sum_{n=0}^{\infty} \frac{2^n}{z^{n+1}} = -\sum_{n=0}^{\infty} (2^n + 1) \frac{1}{z^{n+1}}$

So, we have another expansion here which is valid in this annulus. And now what is interesting that we have positive and negative powers, we have both now in our expansion and this is the typical scenario where we actually have the Laurent series containing positive and negative powers of z .

The third case when $\text{mod } z$ is greater than 2. So, basically here we have 3 region one was with radius one $\text{mod } z < 1$, one was the $\text{mod } z < 2$ we have seen that what kind of expansion we have inside this inner circle, we have seen that what kind of expansion we are going to have in this in this region. And now we will see that what kind of expansion we will expect. Now the outside of this disk here that is $\text{mod } z > 2$ $\text{mod } z > 2$ in this case.

So, having this situation $\text{mod } z > 2$, we have the expansions which is valid, this one in $\text{mod } z > 2$ and this is valid in $\text{mod } z > 1$. So, naturally it is also valid for $\text{mod } z > 2$. So, then we can use these two expansions here, the one here and the other one here. And then we have this series expansion and then we can club it. So here now in this expansion, we are going to have only the negative powers.

So in the outer region of this disc mounted greater than 2. That is the region where we are getting only the negative powers in the annulus, we were getting positive and negative power. And inside that disk where the function was analytic, we were getting only the positive powers of z , well so this weekend club and then we have this in compact form.

(Refer Slide Time: 28:38)

Example: Find the Laurent's series of $f(z) = \frac{1}{(z-1)(z-2)}$ for $1 < |z| < 2$

$$f(z) = \frac{1}{(z-1)(z-2)} = -\frac{1}{z-1} + \frac{1}{z-2} = \frac{1}{z\left(1-\frac{1}{z}\right)} + \frac{1}{-2\left(1-\frac{z}{2}\right)}$$

$$= -\frac{1}{z} \sum_{n=0}^{\infty} \frac{1}{z^n} - \frac{1}{2} \sum_{n=0}^{\infty} \frac{z^n}{2^n}$$

$|z| > 1$ $|z| < 2$

Now we want to write for instance, the Laurent series for this function in this annulus. And the idea is, it is not new now, we can easily frame this from the previous example itself. So we need to get this partial fractions first. And then we know that what is the expansion of this 1 over 1 minus z and what is the expansion of the other one 1 over z minus 2.

So, we can write down the one which is valid for more z greater than 1 and the other one is valid in mod z less than 2. So, this is valid for mod z greater than 1 and then this is mod z less than 2. So, as a whole we have this validity mod z between 1 and 2.

(Refer Slide Time: 29:31)

Example: Find the Laurent's series of $f(z) = \frac{1}{(z-1)(z-2)}$ for $1 < |z| < 2$

$$f(z) = \frac{1}{(z-1)(z-2)} = -\frac{1}{z-1} + \frac{1}{z-2} = -\frac{1}{z\left(1-\frac{1}{z}\right)} + \frac{1}{-2\left(1-\frac{z}{2}\right)}$$

$$= -\frac{1}{z} \sum_{n=0}^{\infty} \frac{1}{z^n} - \frac{1}{2} \sum_{n=0}^{\infty} \frac{z^n}{2^n} = -\left(\frac{1}{z} + \frac{1}{z^2} + \frac{1}{z^3} + \dots\right) - \frac{1}{2} \left(1 + \frac{z}{2} + \left(\frac{z}{2}\right)^2 + \dots\right)$$

$1 < |z|$ $|z| < 2$

$$f(z) = \sum_{n=-\infty}^{\infty} c_n z^n \quad \text{where } c_n = \begin{cases} -1, & n \leq -1 \\ \frac{1}{2^{n+1}}, & n \geq 0 \end{cases}$$

So, exactly the previous example, which we have, have seen, and then we have this expansion containing positive and the negative power because of the annulus. So, if we are

talking about the inside they were the function is analytic we will get only positive power in the annulus where we have some points in the inner integral where the inner circle where the function is not analytic, we will get positive and negative powers and the complete outer region where again your function is analytic, you will get only the negative powers. So, we have just to combine this we have in the compact form this expansion.

(Refer Slide Time: 30:12)

Example: Let $f(z) = \frac{z}{z^2 - 3z + 2}$. Expand $f(z)$ in powers of z in the region

(a) $|z| < 1$ (b) $1 < |z| < 2$ (c) $|z| > 2$

$\frac{1}{1-z} = \sum_{n=0}^{\infty} z^n \quad |z| < 1$
 $= -\sum_{n=0}^{\infty} \frac{1}{z^{n+1}} \quad |z| > 1$

(a) $|z| < 1$ $f(z) = \frac{z}{(z-1)(z-2)} = -\frac{1}{z-1} + \frac{2}{z-2}$

$= \frac{1}{1-z} + \frac{2}{z-2} = \sum_{n=0}^{\infty} z^n + \sum_{n=0}^{\infty} \frac{2^n}{2^{n+1}}$

$\frac{1}{z-2} = -\sum_{n=0}^{\infty} \frac{z^n}{2^{n+1}} \quad |z| < 2$
 $= \frac{1}{z} \sum_{n=0}^{\infty} \frac{2^n}{z^n} \quad |z| > 2$

For instance, if we consider this expansion for this function again this region mod z less than 1 in the annulus and greater than 2. So, it is exactly similar to the previous examples we have done. So, for less than 1 we have to break it and then with these expansions these two expansions which we have already seen, we can write down the series expansion.

So, both we have to observe that this is valid now in mod z less than 1 and this is also valid in mod z less than 2 and therefore, as a whole we are in this range.

(Refer Slide Time: 30:57)

Given function $f(z) = \frac{1}{1-z} + \frac{2}{z-2}$

(b) $1 < |z| < 2$ $f(z) = -\sum_{n=0}^{\infty} \frac{1}{z^{n+1}} - \sum_{n=0}^{\infty} \frac{z^n}{2^{n+1}}$

(c) $|z| > 2$ $f(z) = -\sum_{n=0}^{\infty} \frac{1}{z^{n+1}} + \sum_{n=0}^{\infty} \frac{2^{n+1}}{z^{n+1}}$

$$= \sum_{n=0}^{\infty} \frac{2^{n+1} - 1}{z^{n+1}}$$

$\frac{1}{1-z} = \sum_{n=0}^{\infty} z^n \quad |z| < 1$
 $= -\sum_{n=0}^{\infty} \frac{1}{z^{n+1}} \quad |z| > 1$
 $\frac{1}{z-2} = -\sum_{n=0}^{\infty} \frac{z^n}{2^{n+1}} \quad |z| < 2$
 $= \frac{1}{z} \sum_{n=0}^{\infty} \frac{2^n}{z^n} \quad |z| > 2$

Here again, we can use the same trick. So, third with a mod z is greater than 2 and this can be also done similarly.

(Refer Slide Time: 31:07)

Example: Find the Laurent's series of the function $f(z) = \frac{1}{z^3(1-z)}$ about $z = 1$ in the region $0 < |z-1| < 1$

$f(z) = \frac{-1}{(z-1)(1+(z-1))^3}$

So, this is a little different example where the Laurent series of this function we will see about z equal to 1. So, instead of z equal to 0 in the previous examples, we have now z equal to 1 that means, we are going to have z minus 1 power. So, we have to frame now, this function so, that we have 1 plus z minus 1 or 1 minus z minus 1 kind of form and then we can again expand it.

So, like here we have done so, this z minus 1 which was already there 1 minus z so, we have with minus sign the z minus 1 because we are going to write everything in terms of z minus 1 and the z power 3 we have written 1 plus z minus 1 power 3 again.

(Refer Slide Time: 31:56)

Example: Find the Laurent's series of the function $f(z) = \frac{1}{z^3(1-z)}$ about $z = 1$ in the region $0 < |z - 1| < 1$

$$f(z) = \frac{-1}{(z-1)(1+(z-1))^3} = -\frac{1}{z-1} \left[1 - 3(z-1) + \frac{3 \cdot 4}{2!}(z-1)^2 - \frac{3 \cdot 4 \cdot 5}{3!}(z-1)^3 + \dots \right]$$

Note: $(1+z)^\alpha = 1 + \alpha z + \frac{\alpha(\alpha-1)}{2!}z^2 + \frac{\alpha(\alpha-1)(\alpha-2)}{3!}z^3 + \dots$ where α is a negative integer and $|z| < 1$

So, everything is written now in terms of z minus 1 and we know already this expansion. This is like binomial expansion, so 1 plus z power alpha is 1 plus alpha z and then we have alpha, alpha minus 1 factorial 2 z square and so on.

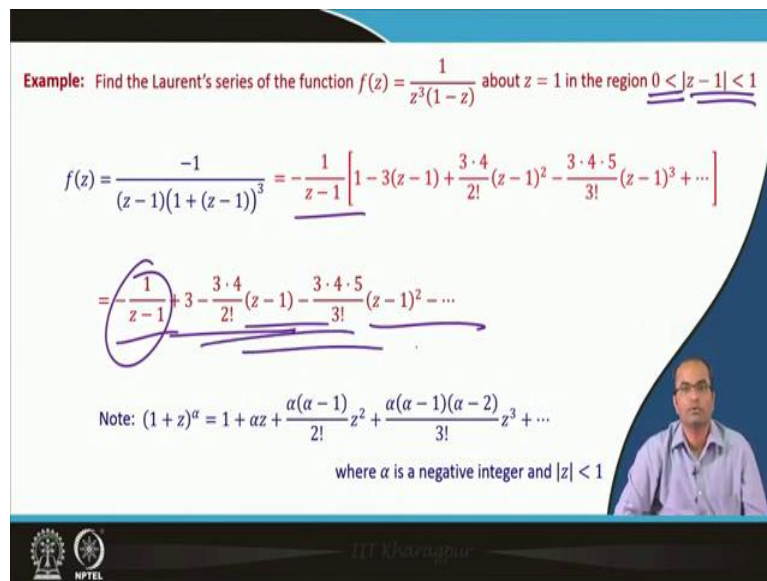

So, this expansion we can use here and then we will get all these powers of z minus 1. Well, so, we have expanded this in using this where the validity region was mod z less than 1. So, here also our validity region is mod z minus 1 less than 1 because we are expanding 1 plus z minus 1. So, mod z minus 1 less than 1 will be the validity region where we are expanding the series here, well.

(Refer Slide Time: 32:45)

Example: Find the Laurent's series of the function $f(z) = \frac{1}{z^3(1-z)}$ about $z = 1$ in the region $0 < |z-1| < 1$

$$f(z) = \frac{-1}{(z-1)(1+(z-1))^3} = -\frac{1}{z-1} \left[1 - 3(z-1) + \frac{3 \cdot 4}{2!}(z-1)^2 - \frac{3 \cdot 4 \cdot 5}{3!}(z-1)^3 + \dots \right]$$
$$= -\frac{1}{z-1} + 3 - \frac{3 \cdot 4}{2!}(z-1) + \frac{3 \cdot 4 \cdot 5}{3!}(z-1)^2 - \dots$$

Note: $(1+z)^\alpha = 1 + \alpha z + \frac{\alpha(\alpha-1)}{2!}z^2 + \frac{\alpha(\alpha-1)(\alpha-2)}{3!}z^3 + \dots$
where α is a negative integer and $|z| < 1$

So, having this expansion and then we can just club it. So, we have these 1, 1 is the negative power and then all other we are getting the positive powers of z because this was also the situation where we have this deleted 0 point and otherwise we have we would have the annulus here, but only the 1 point the z equal to 1 is not in the domain otherwise, this valid in the whole domain except that z equal to 1 point.

CONCLUSION

LAURENT SERIES

$$f(z) = \sum_{n=-\infty}^{\infty} c_n(z-z_0)^n \quad \text{where} \quad c_n = \frac{1}{2\pi i} \oint_C \frac{f(z)}{(z-z_0)^{n+1}} dz$$

PRACTICAL METHODS FOR OBTAINING LAURENT SERIES

$$\frac{1}{1-z} = \sum_{n=0}^{\infty} z^n \quad |z| < 1 \quad , \quad \frac{1}{1-z} = -\sum_{n=0}^{\infty} \frac{1}{z^{n+1}} \quad |z| > 1$$

And just to conclude that this Laurent series will have now the positive and the negative power and this is usually valid in this annulus here and what we have seen that if your function is analytic over the whole disk then you will get the Taylor series, when you have the situation that the function is analytic only in the annulus then you will get positive negative powers.

And when we observe that what will be the expansion outside some disk, then we will get only the negative power. So, in all these examples we have observed that. So we have seen this practical method for obtaining Laurent series, which is very very important. And basically this function works very well.

So, if we have this expansion, the knowledge of this expansion which is valid for mod z less than 1 and the other 1, is mod z valid for mod z greater than 1 then many other functions can be written in this in terms of the simple functions and then we can have, again these expansions in their respective domains, so I thank you for your attention. That is all for this lecture.
