Lecture 19
Singularities

So, welcome back to lectures on Engineering Mathematics 2. So, this is lecture number 19 on Singularities.

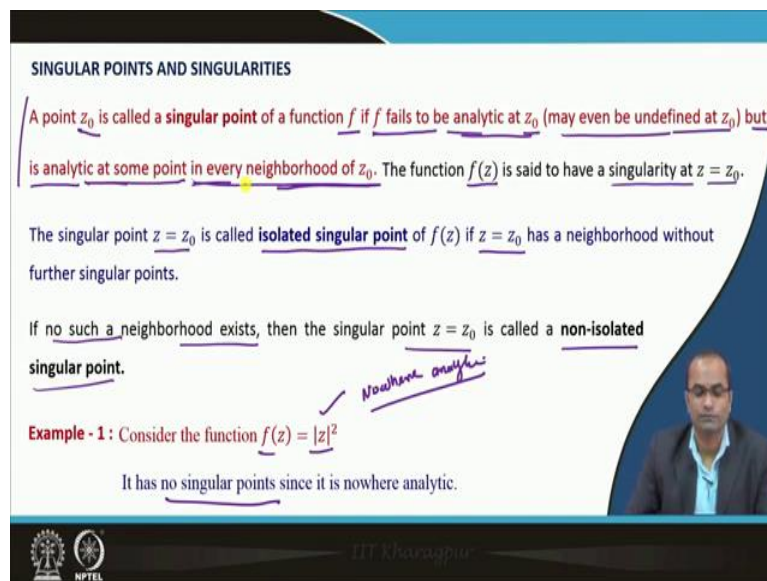

(Refer Slide Time: 00:19)

The slide features a dark blue header with the text 'CONCEPTS COVERED' in white. Below the header, there are two bullet points: 'Singularities' and 'Classification of Singularities'. The slide also includes the logos of IIT Kharagpur and NPTEL in the top left corner. A small yellow star icon is visible on the slide. A video inset of the professor is located in the bottom right corner.

So, today we will discuss what are the singularities of functions of complex variables and then how to classify these singularities into different categories.

(Refer Slide Time: 00:30)

The slide is titled 'SINGULAR POINTS AND SINGULARITIES'. It contains the following text: 'A point z_0 is called a **singular point** of a function f if f fails to be analytic at z_0 (may even be undefined at z_0) but is analytic at some point in every neighborhood of z_0 . The function $f(z)$ is said to have a **singularity** at $z = z_0$.' Below this, it states: 'The singular point $z = z_0$ is called **isolated singular point** of $f(z)$ if $z = z_0$ has a neighborhood without further singular points.' It then says: 'If no such a neighborhood exists, then the singular point $z = z_0$ is called a **non-isolated singular point**.' A handwritten note 'Nowhere analytic' with an arrow points to the example. The example is: 'Example - 1: Consider the function $f(z) = |z|^2$. It has no singular points since it is nowhere analytic.' The slide also includes the logos of IIT Kharagpur and NPTEL in the bottom left corner and a video inset of the professor in the bottom right corner.

So, what is the singular point and what do we mean by singularities? So, a point z_0 is called singular point of a function $f(z)$, so it is a complex valued function, so the function of complex variables, if this function fails to be analytic at z_0 , or this function may not be defined at z_0 , but this function is analytic at some point.

So, there should be at least one point where in the neighbourhood of this z_0 where the function is analytic, then we call such a point a singular point. So, at this point, singular point either the function is not defined or it is not analytic but in the neighbourhood of this z_0 at some point this function is analytic then we call that this is a singular point. And the function $f(z)$ is said to have a singularity at this point z_0 .

So, the singular point z_0 is called isolated singular point of this function $f(z)$, if this z_0 has a neighbourhood without further singular point. So, there must exist in neighbourhood in this neighbourhood of this z_0 where the function does not have a further singular point then we call this isolated singular point.

If no such point in the neighbourhood exist that means every neighbourhood has a singular point then such a singular point is called non-isolated singular point. So, this is what we have discussed what is the singular point and further what is the isolated and non-isolated singular point.

So, consider for example, this function $f(z)$ equal to $|z|^2$ or the absolute value of this z modulus of z square. So, we have already discussed this function and just to recall that this function is nowhere analytic. So, then what we can say about the singular point, so naturally this f fails to be analytic at any point but there is no singular point for this function and the reason is, because this function is nowhere analytic, nowhere analytic.

And therefore we do not have a neighbourhood where the function is analytic. So, we do not have some point in the neighbourhood where the function is analytic, and therefore, according to this definition itself there is no singular point for this function though every point, at every point this function is not analytic.

But this does not have a singular point, so it has no singular point since it is nowhere analytic. So, the second part is not satisfied that the function is analytic at some point in every neighbourhood of z_0 , so this is not possible here because the function is nowhere analytic. So, here there is no singular point for instance for this function.

(Refer Slide Time: 04:08)

Example-2: Consider $f(z) = \tan z$ Isolated singularities at $z = \pm \frac{\pi}{2}, \pm \frac{3\pi}{2}, \dots$ $\tan z = \frac{\sin z}{\cos z}$
 $\cos z = 0$

Example-3: $f(z) = \tan \frac{1}{z} = \frac{\sin \frac{1}{z}}{\cos \frac{1}{z}}$ Singularities point $\cos \frac{1}{z} = 0$

$\Rightarrow \frac{1}{z} = \frac{(2n+1)\pi}{2} \Rightarrow z = \frac{2}{(2n+1)\pi}$ $n = 0, \pm 1, \pm 2, \dots$ These points are isolated singular points.

Note that the function $f(z)$ is not defined at $z = 0$. Therefore $z = 0$ is also a singular point of $f(z)$.

Further $\lim_{n \rightarrow \infty} \frac{2}{(2n+1)\pi} = 0$

Therefore every neighborhood of $z = 0$ contains many singular points.

Example-2: Consider $f(z) = \tan z$ Isolated singularities at $z = \pm \frac{\pi}{2}, \pm \frac{3\pi}{2}, \dots$

Example-3: $f(z) = \tan \frac{1}{z} = \frac{\sin \frac{1}{z}}{\cos \frac{1}{z}}$ Singularities point $\cos \frac{1}{z} = 0$

$\Rightarrow \frac{1}{z} = \frac{(2n+1)\pi}{2} \Rightarrow z = \frac{2}{(2n+1)\pi}$ $n = 0, \pm 1, \pm 2, \dots$ These points are isolated singular points.

Note that the function $f(z)$ is not defined at $z = 0$. Therefore $z = 0$ is also a singular point of $f(z)$.

Further $\lim_{n \rightarrow \infty} \frac{2}{(2n+1)\pi} = 0$

Therefore every neighborhood of $z = 0$ contains many singular points.

Thus $z = 0$ is a **non-isolated singular point**.

However, if we consider fz equal to $\tan z$ for instance, then we have isolated singularities at all these points because this $\tan z$ we can write as $\sin z$ over this $\cos z$ and this $\cos z$ is 0 this $\cos z$ is 0 at all these points π by 2, 3π by 2 with the plus or minus at all these points we have the singularity of this function.

The function will become this infinity, so it is not defined as such so there is no point of analyticity, at all other points the function is analytic and therefore, we, the definition of this singular point is satisfied and all these points are singular point, because in the neighbourhood of these points the function is analytic, only at this point the function is not analytic, and therefore these are the isolated singularities of this function.

If we consider now instead of $\tan z$, $\tan \frac{1}{z}$ in that case we can again write a \sin by this \cos , $\cos \sin \frac{1}{z}$ and again the singularities or say singular points we can discuss by setting this $\cos \frac{1}{z}$ to 0 and again with the same argument what we see that this $\frac{1}{z}$ is $2n\pi + \frac{\pi}{2}$, then this $\cos z$ will become 0 and then we have these singularities.

So, here the z comes to be $\frac{2}{2n\pi + 1}$ into π and for all these n so this function is not analytic, and hence these are the singular points of this function. So, these all are the isolated singular points, because in the neighbourhood we can find the points where the function is analytic.

So, these are the isolated singular points, but what we should note that the fz is also not defined at z equal to 0 because this function is $\tan \frac{1}{z}$, so at z equal 0 also the function is not defined and therefore, this z equal to 0 is also a singular point of this fz . Now, we will see, we will observe that whether it is a isolated or non-isolated singular points.

So, if we notice here that what happened to these points $\frac{2}{2n\pi + 1}$ which are the isolated singular points. If we take n approaches to infinity, so n approaches to infinity this is going to 0. So, for large n as we are approaching n to infinity we are basically approaching to 0 and the 0 is also a singular point.

So, in the neighbourhood of 0, whatever, however, small neighbourhood we take about this z equal to 0 there will be a singular point coming from this sequence of these points, so that is the difference now for z equal to 0 we cannot find a neighbourhood where the function does not have a further singular point. Because the sequence is approaching to 0, so whatever, however, small neighbourhood we take around this z equal to 0 there will be some points which are singular again.

So, this is not a isolated singular point z equal to 0 is not a, not an isolated singular point, indeed it is a non-isolated singular point, because every neighbourhood of this z equal to 0 contains many singular points which are exactly coming with these sequence of points which we have discussed as singular points, so that is an example here where we can see that there are non-isolated singular points as well. So, in this case this z equal to 0 is a non-isolated singular point.

(Refer Slide Time: 08:32)

Isolated singularities of $f(z)$ at $z = z_0$ can be further classified:

1. REMOVABLE SINGULARITIES

- If a single valued function $f(z)$ is not defined at $z = z_0$ but $\lim_{z \rightarrow z_0} f(z)$ exists, then $z = z_0$ is called a removable singularity.

In this case we defined $f(z)$ at $z = z_0$ as equal to $\lim_{z \rightarrow z_0} f(z)$ then $f(z)$ will be analytic at z_0 .

- In case of removable singularity, principal part will not appear in the Laurent's series.

The slide includes a small video inset of a man in the bottom right corner and logos for IIT Kharagpur and NPTEL at the bottom.

So, these isolated singularities of this fz at z equal to z_0 can be further classified, based on the following description, the one is called removable singularities. So, what is removable singularity? If single valued function this fz is not defined at z equal z_0 , if the function is not defined at this point z equal z_0 , however, this limit when we take z to z_0 fz exist then this point is called a removable singular point or it is called removable singularities.

Because in this case if we define the function at z equal to z_0 with this limit which exist then this fz will become analytic at z_0 point and that is the reason we call it as a removable singularity of the function. So, in case of removable singularity and this is the relation which we have with the Laurent series because the Laurent series plays very important role in this classification of this singularities.

So, the first we have discussed this removable singularity and for the removable singularity if we expand the given function about this z equal that z_0 point then in the Laurent series the principal part will not appear that means the negative power of $z - z_0$ will not appear in the Laurent series and then we can so what is the process that around this z equal to z_0 we will expand this function using this the idea of a Laurent series that means the plus positive and the negative powers of $z - z_0$.

And if it comes out to be that the principal part meaning the portion where we have the negative powers of $z - z_0$. So, if those terms do not exist in the Laurent series then we call that this is a removable singularity. So, either the direct we can get using this limit if this limit exist then we also call removable singularity or we will expand into this Laurent

series and if there is no power the negative power of z minus z_0 in the series then we call that this is a removable singularity. So, for each we have these two approaches, one we can classify directly by limit, another one using the Laurent series.

(Refer Slide Time: 11:29)

2. POLE

- If the principal part (P.P.) of the Laurent's series has only finitely many terms, i.e.

$$\text{P.P.} = \frac{b_1}{z - z_0} + \frac{b_2}{(z - z_0)^2} + \dots + \frac{b_m}{(z - z_0)^m}$$

Then the singularity of $f(z)$ at $z = z_0$ is called a **pole of order m** .

Poles of order 1 are called **simple poles**.

- If z_0 is a singular point and we can find a positive integer m such that

$$\lim_{z \rightarrow z_0} (z - z_0)^m f(z) = A \neq 0$$

then $z = z_0$ is called a **pole of order m** .

2. POLE

- If the principal part (P.P.) of the Laurent's series has only finitely many terms, i.e.

$$\text{P.P.} = \frac{b_1}{z - z_0} + \frac{b_2}{(z - z_0)^2} + \dots + \frac{b_m}{(z - z_0)^m}$$

Then the singularity of $f(z)$ at $z = z_0$ is called a **pole of order m** .

Poles of order 1 are called **simple poles**.

- If z_0 is a singular point and we can find a positive integer m such that

$$\lim_{z \rightarrow z_0} (z - z_0)^m f(z) = A \neq 0$$

then $z = z_0$ is called a **pole of order m** .

So, the second category is the pole, we call as a pole that is the name of the singularity the classification of the singularity. So, again if the principal part of this Laurent series has only finitely many term. So, there could be three situations and we have the three classification here, either the Laurent series has no principal part that means no negative powers then such singularity will be treated as removal singularity.

If it has only finitely many terms then this is, these are called the poles and the later on we will see when we have infinitely many terms it is called the sensual singularity. So, let us

discuss this pole there, so if the principal part of this Laurent series has only finitely many terms that means the situation in the principal part is somewhere like this that you have these finitely many terms $b_1 z^{-1}$, $b_2 z^{-2}$ the coefficient we have the second order term and so on we have these m terms.

So, in this case the singularity of $f(z)$ at $z = z_0$ is called the pole, so it is a pole of order m . And the poles of order 1 are called simple poles, so another classification if we use simple pole that means it is a pole of order 1. And if z_0 is a singular point we can also find a positive integer m such that this when we multiply this $f(z)$ by $(z - z_0)^m$ which is clear from this Laurent series as well.

So, when we multiply this by $(z - z_0)^m$ we will have something b_m there that means the constant a which is not equal to 0 and then we call $z = z_0$ a pole of order m , so again here we have the two approaches to classify, one is using Laurent series so if we find the Laurent series has only finitely many terms we will classify such a point as pole of order m , or the another approach we can if we can find a positive integer m such that this $(z - z_0)^m f(z)$ is some constant A which is not equal to 0 then this $z = z_0$ is called a pole of order m .

(Refer Slide Time: 13:52)

3. ISOLATED ESSENTIAL SINGULARITIES

- If the principal part of the Laurent's series

$$f(z) = \sum_{n=0}^{\infty} a_n (z - z_0)^n + \sum_{n=1}^{\infty} \frac{b_n}{(z - z_0)^n}$$
 has infinitely many terms, we say that $f(z)$ has at $z = z_0$ an isolated essential singularity.
- A isolated singularity that is not a pole or removable singularity is called an essential singularity.

The slide includes a video inset of a speaker in the bottom right corner and logos for IIT Kanpur and NPTEL at the bottom.

Well, so the third one. So, this is the third one now is called the isolated essential singularities, so in this case if the principal part of the Laurent series, so this is the Laurent series. If it has infinitely many terms, so infinitely many terms then we called that $f(z)$ has at $z = z_0$ an isolated essential singularity.

So, this is the third classification which we have, which we are discussing now. And further, another way we also define this isolated essential singularity which is not a pole or which is not a removable singularity is called essential singularity. So, isolated singularity which is not a pole and not a removable singularity we will call as essential singularity, because either this Laurent series will have no term or it will have finitely many terms or it will have infinitely many terms. So, these three classification we can have for the isolated singularities.

(Refer Slide Time: 15:00)

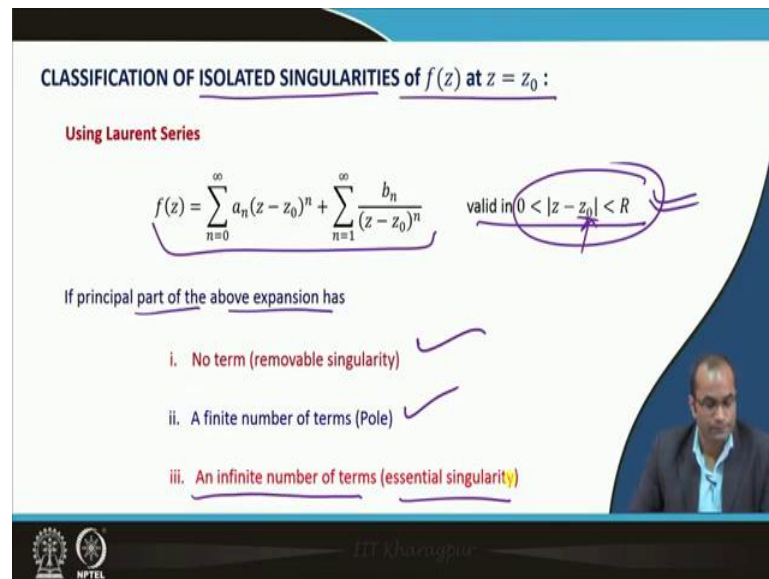

CLASSIFICATION OF ISOLATED SINGULARITIES of $f(z)$ at $z = z_0$:

Using Laurent Series

$$f(z) = \sum_{n=0}^{\infty} a_n (z - z_0)^n + \sum_{n=1}^{\infty} \frac{b_n}{(z - z_0)^n} \quad \text{valid in } 0 < |z - z_0| < R$$

If principal part of the above expansion has

- i. No term (removable singularity) ✓
- ii. A finite number of terms (Pole) ✓
- iii. An infinite number of terms (essential singularity) ✓

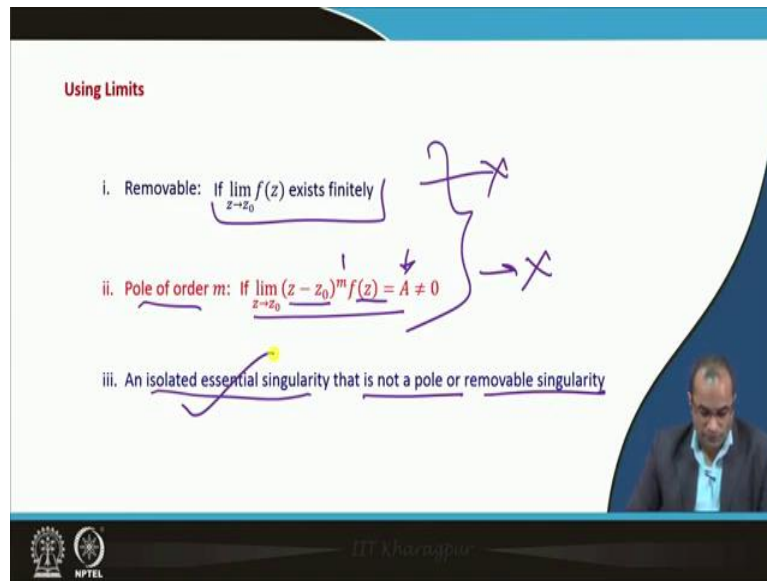

So, just to summaries what we have done these isolated singularities at z equal to z naught, using the Laurent series we can classify. So, we will expand the Laurent series in this region around z equal to z naught point the singular point which we want to classify, so we will do this expansion there and if this principal part of this above expansion has no term we call removal singularity, if it has finite number of terms we call pole and depending on the number of terms we also say the pole of order m or pole of order 1 are called simple poles. And if it has infinitely many terms then we call that this singularity is an essential singularity.

(Refer Slide Time: 15:49)

Using Limits

- i. Removable: If $\lim_{z \rightarrow z_0} f(z)$ exists finitely
- ii. Pole of order m : If $\lim_{z \rightarrow z_0} (z - z_0)^m f(z) = A \neq 0$
- iii. An isolated essential singularity that is not a pole or removable singularity

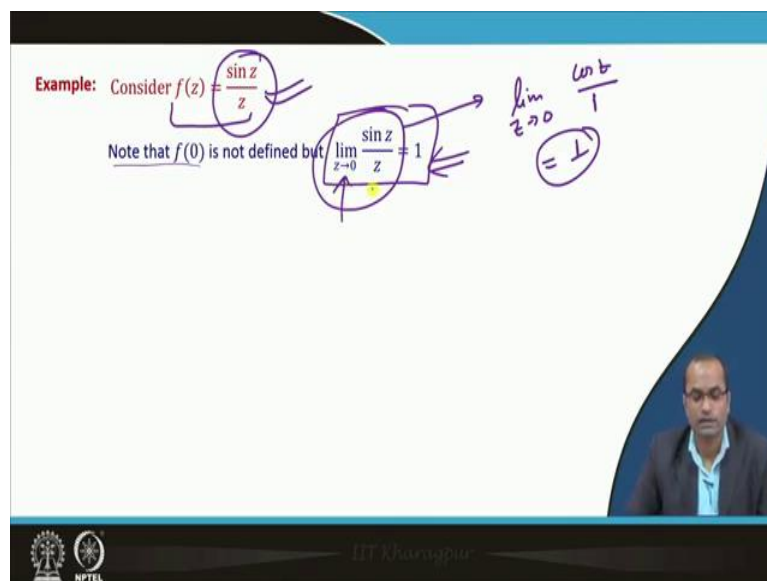

So, using limit also we can classify, so for the removable we have observe that if this limit exist as a finite number, pole of order m if we can find an m where z minus z_0 power m and fz equal to A , some finite number exist then we call this is a pole of order m and for the isolated singularity we just classify which is not a pole and not a removable singularity with the earlier approach here with the limits if we see that this is not a removable singularity, this is not a pole then this is going to be an essential singularity.

(Refer Slide Time: 16:40)

Example: Consider $f(z) = \frac{\sin z}{z}$

Note that $f(0)$ is not defined but $\lim_{z \rightarrow 0} \frac{\sin z}{z} = 1$

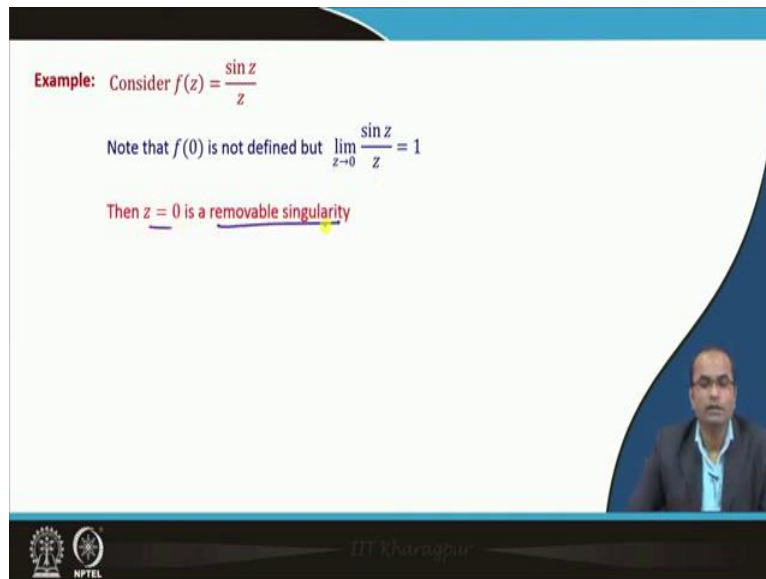

$\lim_{z \rightarrow 0} \frac{\sin z}{z} = 1$

Example: Consider $f(z) = \frac{\sin z}{z}$

Note that $f(0)$ is not defined but $\lim_{z \rightarrow 0} \frac{\sin z}{z} = 1$

Then $z = 0$ is a removable singularity

So, with this classification now we can go through some of the examples, the one the $\sin z$ over z we discussed, so we consider this fz as a function fz over z and in this case we note that this fz is not defined but if we consider this limit here as z approaches to z naught, $\sin z$ over z . So, this that there be the L'Hopital rule is applicable, so here we have 0 by 0 form and then the limit z approaches to 0 we have the $\cos z$ and then $(\cos 0)$ is 1 so this limit is 1 .

So, this limit exist and that was the, that was the only critical point at z equal to 0 but here we see that not the critical point, the singular point and there we see that this limit exist at when a z approaches to z naught for this function $\sin z$ over z and we therefore we call that this is a removable singularity as per the description before.

(Refer Slide Time: 17:46)

Example: Consider $f(z) = \frac{\sin z}{z}$

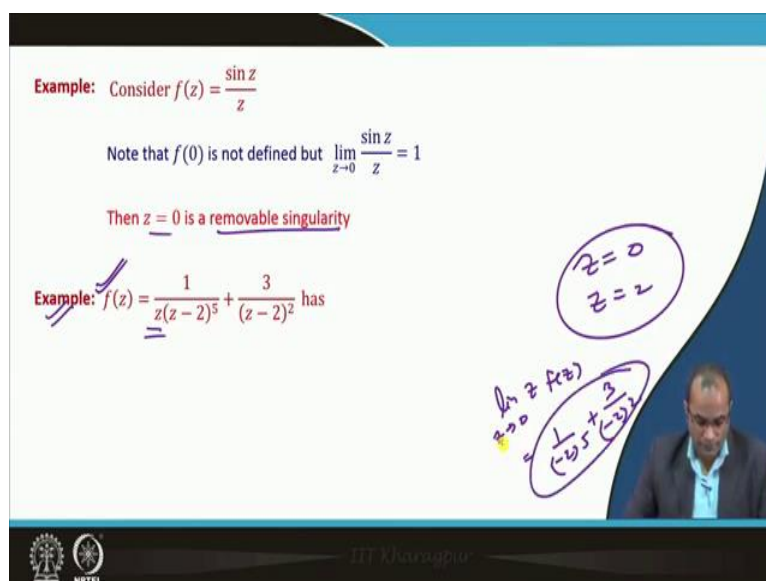

Note that $f(0)$ is not defined but $\lim_{z \rightarrow 0} \frac{\sin z}{z} = 1$

Then $z = 0$ is a removable singularity

Example: $f(z) = \frac{1}{z(z-2)^5} + \frac{3}{(z-2)^2}$ has

$z=0$
 $z=2$

$\lim_{z \rightarrow 0} f(z) = \frac{1}{(-2)^5} + \frac{3}{(-2)^2}$

The second example we take $f(z) = \frac{1}{z(z-2)^5} + \frac{3}{(z-2)^2}$. Then we have this $\frac{3}{(z-2)^2}$ and then we have here the $\frac{1}{z(z-2)^5}$. So, we are discussing now the singularity of this function so naturally $z = 0$ and $z = 2$, these are two singular points, but we want to classify them whether they are removable singularity pole of what order or the essential singularity.

So, in this case this $z = 0$ it is clearly when we multiply by z there and then take the limit $z \rightarrow 0$ something finite will happen, so if we multiply this z $f(z)$ and then take the limit as z approaches to 0, so what will happen. So, here 1 over this $(z-2)^5$ and then 3 over $(z-2)^2$, so this is a finite number and therefore this is a pole of order, order 1.

(Refer Slide Time: 19:03)

Example: Consider $f(z) = \frac{\sin z}{z}$

Note that $f(0)$ is not defined but $\lim_{z \rightarrow 0} \frac{\sin z}{z} = 1$

Then $z = 0$ is a removable singularity

Example: $f(z) = \frac{1}{z(z-2)^5} + \frac{3}{(z-2)^2}$ has

Handwritten notes:
 $\lim_{z \rightarrow 2} \frac{(z-2)^5 f(z)}{3(z-2)^2}$
 $\lim_{z \rightarrow 2} \frac{1}{z} = \frac{1}{2}$
 $\lim_{z \rightarrow 2} \frac{3}{(z-2)^2} = \infty$

Example: Consider $f(z) = \frac{\sin z}{z}$

Note that $f(0)$ is not defined but $\lim_{z \rightarrow 0} \frac{\sin z}{z} = 1$

Then $z = 0$ is a removable singularity

Example: $f(z) = \frac{1}{z(z-2)^5} + \frac{3}{(z-2)^2}$ has a simple pole at $z = 0$ and a pole of order 5 at $z = 2$.

Handwritten notes:
 $\frac{1}{z} = 1 + \frac{1}{z} + \frac{1}{2!z^2} + \dots$

Example: Consider $f(z) = \frac{\sin z}{z}$

Note that $f(0)$ is not defined but $\lim_{z \rightarrow 0} \frac{\sin z}{z} = 1$

Then $z = 0$ is a removable singularity

Example: $f(z) = \frac{1}{z(z-2)^5} + \frac{3}{(z-2)^2}$ has a simple pole at $z = 0$ and a pole of order 5 at $z = 2$

Example: The function $e^{\frac{1}{z}}$ has essential singularity at $z = 0$ as

$$e^{\frac{1}{z}} = 1 + \frac{1}{z} + \frac{1}{2!z^2} + \dots$$

And now for the second part what we will do now because if you multiply by $z - 2$ whole square and then take the limit $z \rightarrow 2$ and this $z - 2$ some power we will see what power we should take, so that we get some finite number, so if we take for instance the power 1 or 2 in this case this will be 3 but the first term will have something going to infinity so this is not going to help.

So till that time we go to the power 5 here because if we go beyond 5 then it will become 0, this limit will become 0 so that also we are not looking for, so if we take this power 5 so we just 1 over z there and then here 3 this $z - 2$ the cube will be there and if we take the limit z approaches to 2 now.

So, due to first term it is 1 by 2 and the second term is 0 so we have something finite which is not equal to 0 or infinity. So, here what we observe now that this function has at $z = 0$ a simple pole a pole of order 1 and at $z = 2$ it has a pole of order 5, so it has a simple pole at $z = 0$ and a pole of order 5 at $z = 2$. Just looking at the given function itself we can conclude without evaluation if the scenario is that much simple that what kind of classification we have for the singularities.

Another example we will consider here, that this function $e^{1/z}$ and what we observe that this has an essential singularity at $z = 0$ and the reason is clear that this exponential $1/z$ if we expand in terms of z in terms of powers of z , so what we observe that the expansion has 1 plus 1 over z , 1 over z^2 , 1 over z^3 and there will be infinitely many terms in the expansion and so the negative, the principal part has infinitely many terms of this 1 over z .

And therefore, this z equal to 0 is the essential singularity in this case we do not have to check with any the limiting case whether it can be a pole or anything that is not possible, so here it is a essential singularity therefore.

(Refer Slide Time: 21:42)

Example: Singularities of the function $f(z) = \tan z = \frac{\sin z}{\cos z}$

Singularities: $z = \frac{\pi}{2} + m\pi, \quad m = 0, \pm 1, \pm 2, \dots$

$\lim_{z \rightarrow \frac{\pi}{2} + m\pi} f(z)$ does not exist finitely. Hence, there are no removable singularity.

$\lim_{z \rightarrow \frac{\pi}{2} + m\pi} \left(z - \left(\frac{\pi}{2} + m\pi \right) \right) \frac{\sin z}{\cos z} = \lim_{z \rightarrow \frac{\pi}{2} + m\pi} \frac{\left(z - \left(\frac{\pi}{2} + m\pi \right) \right)}{\frac{\cos z}{\sin z}} \left(\frac{0}{0} \text{ form} \right)$

NPTEL IIT Kharagpur

Example: Singularities of the function $f(z) = \tan z = \frac{\sin z}{\cos z}$

Singularities: $z = \frac{\pi}{2} + m\pi, \quad m = 0, \pm 1, \pm 2, \dots$

$\lim_{z \rightarrow \frac{\pi}{2} + m\pi} f(z)$ does not exist finitely. Hence, there are no removable singularity.

$\lim_{z \rightarrow \frac{\pi}{2} + m\pi} \left(z - \left(\frac{\pi}{2} + m\pi \right) \right) \frac{\sin z}{\cos z} = \lim_{z \rightarrow \frac{\pi}{2} + m\pi} \frac{\left(z - \left(\frac{\pi}{2} + m\pi \right) \right)}{\frac{\cos z}{\sin z}} \left(\frac{0}{0} \text{ form} \right)$

$= \lim_{z \rightarrow \frac{\pi}{2} + m\pi} \frac{1}{-\sin z \sin z - \cos z \cos z} = -1$

NPTEL IIT Kharagpur

Example: Singularities of the function $f(z) = \tan z = \frac{\sin z}{\cos z}$

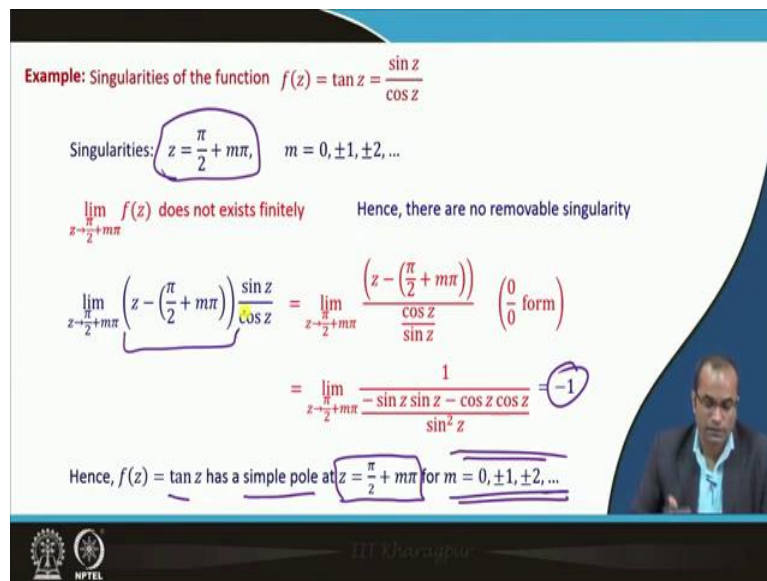

Singularities: $z = \frac{\pi}{2} + m\pi, \quad m = 0, \pm 1, \pm 2, \dots$

$\lim_{z \rightarrow \frac{\pi}{2} + m\pi} f(z)$ does not exist finitely. Hence, there are no removable singularity.

$$\lim_{z \rightarrow \frac{\pi}{2} + m\pi} \left(z - \left(\frac{\pi}{2} + m\pi \right) \right) \frac{\sin z}{\cos z} = \lim_{z \rightarrow \frac{\pi}{2} + m\pi} \frac{\left(z - \left(\frac{\pi}{2} + m\pi \right) \right)}{\frac{\cos z}{\sin z}} \quad \left(\frac{0}{0} \text{ form} \right)$$

$$= \lim_{z \rightarrow \frac{\pi}{2} + m\pi} \frac{1}{-\sin z \sin z - \cos z \cos z} = -1$$

Hence, $f(z) = \tan z$ has a simple pole at $z = \frac{\pi}{2} + m\pi$ for $m = 0, \pm 1, \pm 2, \dots$

Now, if you want to discuss the singularity of the function $\tan z$ which is $\sin z$ over $\cos z$, so we have already discussed that these are the singular points for this function and now we will classify them to see what kind of singularities this function has. So, here if we take just the limit as z approaches to $\frac{\pi}{2} + m\pi$ of this $f(z)$ we will notice that this limit does not exist, so it does not exist finitely because of this $\cos z$ that will go to 0 so we have the infinity there.

So, naturally this does not exist, so it is a removable singularity that is clear just by taking this limit itself, because the numerator $\sin z$ will approach 1 and this will approach 0 so that will go to infinity so this does not exist, so we will try now with this multiplication of z minus z_0 , so the z_0 is $\frac{\pi}{2} + m\pi$ the general z_0 we are considering.

So, if we multiply this by $\frac{\sin z}{\cos z}$ by $z - z_0$, so in that case what we observe that we have a 0 and this we have written as $\frac{\cos z}{\sin z}$ so this $\cos z$ is 0 again and this is going to 1 so we have the 0 term here and 0 in the numerator so we have this 0 by 0 form and therefore we can apply this L'Hopital rule and see what comes out, so from the numerator we are getting 1 when we go for the differentiation and the differentiation of this $\cos z$ over z by this $(\frac{0}{0})$ rule we have this expression.

So, in this case when this z goes to $\frac{\pi}{2} + m\pi$ we observe that this is going to be 1 and then here we have this 0 and then again 1 there, so minus 1 we are getting as a value of this expression that means this limit exists now finitely we have the number 1 minus 1, it means that all these points here $z = \frac{\pi}{2} + m\pi$ they are basically simple poles.

So, this $\tan z$ has simple pole at this point or all these points indeed because these are infinitely many points. So, we have classified with the help of this limit their, though we can do with this expansion Laurent's expansion as well, so their classification can be done with the Laurent series.

(Refer Slide Time: 24:28)

Example: Classify the singularity points of the function $f(z) = \frac{z}{(z^2 + 4)^2}$

$$f(z) = \frac{z}{(z^2 + 4)^2} = \frac{z}{(z - 2i)^2(z + 2i)^2}$$

Method-I

$$\lim_{z \rightarrow 2i} (z - 2i)^2 f(z) = \lim_{z \rightarrow 2i} \frac{z}{(z + 2i)^2} = \frac{2i}{16i^2} = \frac{1}{8i} \neq 0$$

$\Rightarrow z = 2i$ is a pole order 2.

\Rightarrow similarly for $z = -2i$, we can check that $z = -2i$ is a pole of order 2

Now, you want to do classify this singular points of, of this function fz equal to z over z square plus 4, so first we will find out what are the zeros here for this function means where the these singular points, so this is we can be written as z square minus this $2i$ whole square and then we have the square there.

So, this z over z plus $2i$ whole square and z minus $2i$ square, so now the singular points are clear we have the minus $2i$ and the $2i$ these are the singular points, so if we consider this limit z minus $2i$ square so in this situation now it is clear that if we take the square there and then take the limit z equal to $2i$ we are expecting to get a finite term now.

So, the remaining portion now when we this z minus $2i$ square will get cancel, so we have z over z plus $2i$ whole square and z approaches to $2i$, so it is $4i$ and then square so $16i$ square that means we are getting 1 over $8i$ so it is a finite number, so here with this 2 it works to get the finite number indeed if you increase this power 3 then it will be 0 , if you decrease that power to be infinity, so this is the only possibility to get something nonzero and finite number for this limit.

So, we have this pole of order 2 and similarly we can observe that as z equal to minus $2i$ also has a pole of order 2, so not equal to 0 so it is a pole of order 2 and similarly z equal to minus $2i$ we can check that this is also a pole of order 2.

$$f(z) = \frac{z}{(z^2 + 4)^2} = \frac{z}{(z^2 - (2i)^2)^2} = \frac{z}{(z + 2i)^2(z - 2i)^2}$$

Method-II Write Laurent Series for $z = 2i$ [powers of $(z - 2i)$]

$$f(z) = \frac{z}{(z^2 + 4)^2} = \frac{z}{(z^2 - (2i)^2)^2} = \frac{z}{(z + 2i)^2(z - 2i)^2}$$

Method-II Write Laurent Series for $z = 2i$ [powers of $(z - 2i)$]

$$f(z) = \frac{1}{8i} \left[\frac{1}{(z - 2i)^2} - \frac{1}{(z + 2i)^2} \right] = \frac{1}{8i} \left[\frac{1}{(z - 2i)^2} - \frac{1}{(z - 2i + 4i)^2} \right]$$

$$= \frac{1}{8i} \left[\frac{1}{(z - 2i)^2} + \frac{1}{16} \left\{ 1 + \frac{z - 2i}{4i} \right\}^{-2} \right]$$

valid in $0 < |z - 2i| < 4$

$$= \frac{1}{8i} \left[\frac{1}{(z - 2i)^2} + \frac{1}{16} \left\{ 1 - \frac{z - 2i}{2i} + \text{higher powers of } (z - 2i) \right\} \right]$$

$$f(z) = \frac{z}{(z^2 + 4)^2} = \frac{z}{(z^2 - (2i)^2)^2} = \frac{z}{(z + 2i)^2(z - 2i)^2}$$

Method-II Write Laurent Series for $z = 2i$ [powers of $(z - 2i)$]

$$f(z) = \frac{1}{8i} \left[\frac{1}{(z - 2i)^2} - \frac{1}{(z + 2i)^2} \right] = \frac{1}{8i} \left[\frac{1}{(z - 2i)^2} - \frac{1}{(z - 2i + 4i)^2} \right]$$

$$= \frac{1}{8i} \left[\frac{1}{(z - 2i)^2} + \frac{1}{16} \left\{ 1 + \frac{z - 2i}{4i} \right\}^{-2} \right] \quad \text{valid in } 0 < |z - 2i| < 4$$

$$= \frac{1}{8i} \left[\frac{1}{(z - 2i)^2} + \frac{1}{16} \left\{ 1 - \frac{z - 2i}{2i} + \text{higher powers of } (z - 2i) \right\} \right]$$

$\Rightarrow z = 2i$ is a pole order 2.

\Rightarrow similarly for $z = -2i$, we can check that $z = 2i$ is a pole of order 2

So, having this partial fraction, we can also observe looking at the series expansion for this the Laurent series expansion for this function and then again we can observe that these are the poles, so this is method 2 we are going to now have. So, for the Laurent series at z equal to $2i$ that means the powers of z minus $2i$ we are going to have this expansion.

So, z minus $2i$ power whole square, one term is already there so that we will not touch when we do this partial fractions here, so 1 over this z plus $2i$ square we can expand in terms of z minus $2i$ powers. So, we can rewrite this z minus $2i$ and then to compensate this we have this $4i$ square and then we will take this 16 common from here the $4i$ this square terms.

So, $16i$ square that minus minus will become plus and we have here 1 plus z minus $2i$ over $4i$ whole square and this is valid now in this region z minus $2i$ less than 4 so that can be just done by setting this that z minus this $2i$ over $4i$ should be less than 1 from here we are getting this region of expansion.

So, exactly this is the region which we want to expand the whole function to see the, to see the, to classify the singularity and in this case, so we have 1 over z minus 2 square and then 1 by 16 and here when we expand so we have 1 minus z minus $2i$ over $2i$ and the higher order powers naturally will appear for z minus $2i$.

So, this is the term which is coming in the negative power of so up to 2 , the order 2 we are going here, so that means this is a pole of order, order 2 . So, in this way also it is very easy to classify these singularities, so similarly $4z$ equals to minus $2i$ now we can expand in terms of z plus $2i$ and again we will observe the same situation that this is a pole of order 2 .

Pole of order m

Essential

CONCLUSION

Classification Using Laurent Series Using Limits

If P.P. of the Laurent expansion has

- i. No Term
- ii. A finite number of terms (m)
- iii. An infinite number of terms

Singular Point
A point z_0 is called a **singular point** of a function f if f fails to be analytic at z_0 but is analytic at some point in every neighborhood of z_0 .

i. If $\lim_{z \rightarrow z_0} f(z)$ exists finitely

ii. If $\lim_{z \rightarrow z_0} (z - z_0)^m f(z) = A \neq 0$

iii. not a pole or removable singularity

Removable

Pole of order m

Essential

And just to conclude now, so we have discussed singular points today it is a very important topic in, in complex analysis and some of the applications we will observe in the next lecture. So, a point z_0 is called a singular point of a function f if this f fails to be analytic and most important is the second part also that it is not only just failing to be analytic at z_0 , but it should be analytic at some point in every neighbourhood of z_0 and the example we have seen this $\text{mod } z$ square which can be explain now with the this definition that this $\text{mod } z$ square has now singular point.

So, then we have discussed the classification and the first was what is the removable singularity, so using the Laurent series we have observed that if the principal part of the Laurent series has no term then we call it as removable singularity, the second using the limit we have discussed and their we discussed that if this limit here exist finitely then also we call it as removable singularity.

So, depending on the convenience of whether the Laurent series expansion is easy to perform or using this limit we can check whether it is removable singularity or different kind of singularity. So, the pole of order m that was a second classification for the singularities isolated singularities, so a finite number of terms that is means these m , first m appear there, then we call this pole of order m or we can find such m where this $z - z_0$ power m fz is a finite number in that case also we can classify, so that is using limit.

The essential singularity we call when the this Laurent series has infinitely many terms and using the limit we observe that if it is not a pole or not a singularity by these methods we can classify this that this is essential singularity in that case. So, that is all for this lecture and I thank you for your attention.
