**Trigonometric Polynomials and Series**

So, welcome back to lectures on Engineering Mathematics 2, so this is module number 4 on Fourier series and Integral transforms. Lecture number 31 and today we will discuss on trigonometric polynomials and trigonometric series.

(Refer Slide Time: 00:28)

So, just first, let me tell you what we will be covering in this module four, so it's Fourier series on and this integral transforms. So, there will be naturally 2 different sections so 1 will be on Fourier series and other 1 on integral transform. So, Fourier series mainly we will their its used in a nut shell to approximate the function using sin and cosine functions which are simple and then also periodic.

So, and the second portion the other applications so we will be also talking about some applications so the Fourier series has several applications including this analysis of this current flow sound waves, in image analysis, and solution of many differential equations including partial differential equations etcetera.

The second portion will we be on integral transform and we will observe there is a connection from this Fourier series to the integral transforming particular the Fourier transform. So, that will be also studied and we will be talking about in general two types of integral transform 1 will be

on Fourier transform, so that is exactly related to the Fourier series. And we will see the transformation from the Fourier series to the integral transform. There will be one more integral transform, the Laplace transform will be discussing in this lecture in this module.

And concerning this integral transform so we can explain in this way basically the motivation behind this integral transform, so will be covering this portion that the initial and boundary value problem and we try to solve directly. So, this getting the solution is very difficult for in this initial value and the boundary value problem. So, they are the differential equations associated with some kind of conditions to have unique solutions. So, those portion you will be covering in those particular lectures.

So, what we do usually we apply the integral transform to the initial value and the boundary value problem which is normally easy. And it converts the problem to a simple problem either algebraic problem or we are talking about the partial differential equations there than this integral transform will convert to the ordinary differential equations.

And in either both of them are easy to solve and then we apply the integral transform to get the solution again. So, this is a kind of technique which will be demonstrated in our lectures to get the solution of the differential equations using this integral transform. And directly if we try to get those solutions there will be very difficult but with the help of the integral transforms they will become very easy.

So, we will start with the Fourier series there will be about 10 lectures on Fourier series and followed by the 10 lectures on Fourier transform and then about 10 lectures again on Laplace transform.

(Refer Slide Time: 03:53)

The slide features a dark blue header with the text "CONCEPTS COVERED" in white. Below the header, a list of topics is presented with red arrowheads pointing to the right. The items are: "Periodic Functions", "Trigonometric Polynomials" (with a blue arrow pointing left), "Trigonometric Series", and "Trigonometric System" (which is circled in blue). In the bottom right corner, there is a small inset video of a man in a suit.

So, in this today's lecture we will be discussing what are the periodic functions because there is a connection of the Fourier series to periodic function. So, we will start with what are the periodic functions and then this is a very basic introduction to get prepared for discussing the Fourier series or to construct the Fourier series in the next lecture. So, we will be talking about the trigonometric polynomials and trigonometric series, and further as a whole we will be also using this term trigonometric system in today's lecture.

(Refer Slide Time: 04:35)

The slide is titled "Periodic Functions" in red. It contains the following text: "If a function  $f$  is periodic with period  $T > 0$  then" followed by the equation  $f(t) = f(t + T), -\infty < t < \infty$ . A blue arrow points to the right of the equation, and another blue arrow points upwards from the equation to the text below. The text below reads: "The smallest of  $T$ , for which the equality  $f(t) = f(t + T)$  is true, is called fundamental period of  $f(t)$ ". The equation  $f(t) = f(t + T)$  is circled in blue. In the bottom right corner, there is a small inset video of a man in a suit.

**Periodic Functions**

If a function  $f$  is periodic with period  $T > 0$  then

$$f(t) = f(t + T), -\infty < t < \infty$$

The smallest of  $T$ , for which the equality  $f(t) = f(t + T)$  is true, is called fundamental period of  $f(t)$

However, if  $T$  is the period of a function  $f$  then  $nT$ ,  $n$  is any natural number, is also a period of  $f$

So, let me start with this periodic functions, so if a function  $f$  is periodic with period this  $T$  then the  $f(t)$  the function value at  $t$  must be equal to the function value at  $t$  plus this  $T$ . And then, we call that this  $T$  is the period of the function and the function is periodic if this property holds for all  $t$ . And the smallest value of  $t$  this capital  $T$  which we are calling period for which this equality holds.

Because once I mean we will observe also later that once we find some this capital  $T$  such that this property holds here than the  $2t$  or the  $3t$  any integer multiple of this  $t$  will also work and this property will be true. So, if  $f(t)$  is equal to  $f(t + p)$  plus this capital  $T$  than also  $f(t)$  is equal to  $f(t + 2)$  times capital  $T$  or  $2$  times  $3t$  etcetera.

So, the smallest value for which this equality is true is called the fundamental period of the function  $f(t)$ , so I if this  $t$  is the period of the function  $f$  than  $nt$  which I have just discussed for any a natural number is also a period of  $t$ . And as a whole we are talking about the smallest of such  $t$  for which this equality is true and this is called the fundamental period of  $t$ .

**Properties of Periodic Functions**

1. It should be noted that the sum, difference, product and quotient of two functions is also a periodic function.

$$f(x) = \sin x + \sin 2x + \sin 3x$$

Period:  $\underbrace{2\pi}$ ,  $\underbrace{\frac{2\pi}{2} = \pi}$ ,  $\underbrace{\frac{2\pi}{3}}$

NPTEL IIT Kharyagpur

**Properties of Periodic Functions**

1. It should be noted that the sum, difference, product and quotient of two functions is also a periodic function.

$$f(x) = \sin x + \sin 2x + \sin 3x$$

Period:  $\underline{\underline{2\pi}}$ ,  $\underline{\underline{\frac{2\pi}{2} = \pi}}$ ,  $\underline{\underline{\frac{2\pi}{3}}}$

NPTEL IIT Kharyagpur

**Properties of Periodic Functions**

1. It should be noted that the sum, difference, product and quotient of two functions is also a periodic function.

$$f(x) = \sin x + \sin 2x + \sin 3x$$

Period:  $2\pi$ ,  $\frac{2\pi}{2} = \pi$ ,  $\frac{2\pi}{3}$

Period of  $f = \text{common period of } (\sin x, \sin 2x, \sin 3x) = 2\pi$

$$f(x + 2\pi) = \sin(x + 2\pi) + \sin(2x + 2\pi) + \sin(3x + 2\pi)$$

$$= \sin(x) + \sin(2x) + \sin(3x) = f(x)$$

So, there are some interesting properties of the period function some of them I will list here, so the first one that the some difference product or quotient of two functions is also periodic. So, if we have two functions there sum will be also periodic their product will also periodic their difference will also periodic their quotient will also periodic.

This is a nice property we have for this periodic function. So, for instance if we take this  $f(x)$  is equal to  $\sin x$  plus  $\sin 2x$  plus  $\sin 3x$  so we have added 3 periodic function so it is well known that the  $\sin x$  is a periodic function or  $\sin 2x$  or  $\sin 3x$  all these are periodic functions with different period different fundamental period.

So, what is the period here for this function which is sum of the 3 different periodic functions, so the period we will look individually first. So, what is the period of this first function that is  $2\pi$  its known and for  $2x$  when are talking about  $\sin 2x$  the period will be half because we are talking about  $2x$  there. So, usually we compute  $2\pi$  and divided by this number will give the period of this sin or cosine function. So, here we have the period  $\pi$  and similarly for the  $\sin 3x$  we have  $2\pi$  over this number 3 here. So, here the period is  $2\pi$  by 3, so  $2\pi$  period  $\pi$  period and then  $2\pi$  by 3 period.

So, to get the period of this sum what we have to do we have to just find the common period of all this functions. So, for example  $\sin 2x$  has  $2\pi$  period than this  $\sin 2x$  has  $\pi$  period but we also in the previous slide we have already discussed that if  $\pi$  is the period so if it is repeat repeating its value after  $\pi$ , definitely it will also repeat its value after  $2\pi$ .

So, and as a result, we are calling that if  $\pi$  is the period then  $n\pi$  is also a period, so here the  $2\pi$  is also period for this function. And for this function if I multiply by 3 so again the  $2\pi$  is also period of that function. So, the common period of all these 3 functions what we observe is actually a  $2\pi$  and as a result we can tell something about the period of this  $f(x)$  because this is repeating its value after  $2\pi$  period. This is repeating after  $\pi$  and naturally after  $2\pi$  also and this is also repeating after  $2\pi$ .

So, the sum will also as the sum function will also repeat its value after this  $2\pi$  period which is the common period of all these functions  $\sin x$ ,  $\sin 2x$  and  $\cos 3x$ . So it's a  $2\pi$  here, we can observe we can clearly see that  $f(x + 2\pi)$  is equal to  $\sin(x + 2\pi)$ ,  $\sin(2x + 2\pi)$  and  $\cos(3x + 2\pi)$  we have added this  $4x$  we have listed here  $x + 2\pi$ .

So, what will happen so here  $f(x)$  is replaced by  $x + 2\pi$  here also  $x + 2\pi$  so this will become as  $4\pi$  this will become as  $6\pi$  whatever. So, here this  $\sin(x + 2\pi)$  is  $\sin x$  here also  $\sin(x + 4\pi)$  is also  $\sin x$  and this is also  $\cos x$  because all these functions have the period  $\pi$ ,  $2\pi$  or  $2\pi$  by 3.

So, this is  $\sin x$ ,  $\sin 2x$ ,  $\cos 3x$  again the same function  $f(x)$  and therefore this is a periodic function with period  $2\pi$  because  $f(x + 2\pi)$  we are getting this  $f(x)$  and then this is indeed the fundamental period because the common period is  $2\pi$  and not less than  $2\pi$ . So, that is going to be also the fundamental period.

(Refer Slide Time: 10:55)

2. If a function is integrable on any interval of length  $T$ , then it is integrable on any other intervals of the same length and the value of the integral is the same, that is,

$$\int_a^{a+T} f(x) dx = \int_b^{b+T} f(x) dx = \int_0^T f(x) dx$$

Dr. B. K. Choudhary

NPTEL

2. If a function is integrable on any interval of length  $T$ , then it is integrable on any other intervals of the same length and the value of the integral is the same, that is,

$$\int_a^{a+T} f(x) dx = \int_b^{b+T} f(x) dx = \int_0^T f(x) dx$$

Dr. Khosravian

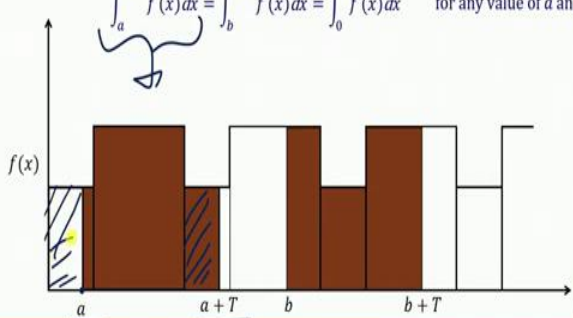

So, another interesting property which we will discuss here so if a function is integrable on any interval of length  $t$  than it is integrable on any other interval of the same length. And the value the interesting point is that the value of the integral is same over as long as the length of the interval is same and we are talking about the periodic function as its integrant than the value of all the integrals will be equal only we have to see that the length of the of the interval were we are integrating this.

So, the then the value of the integral is going to be same so let me just elaborate more, so here if  $fx$  is periodic with period  $t$  then if we integrate this  $a$  to  $a$  plus  $t$  the value will be same if we integrate from other point  $b$  to  $b$  plus  $t$   $b$  plus  $t$ . So, here the length is  $t$  here also the length of this interval is  $t$  and that value will be same if we integrate from  $0$  to  $T$  so in the whole this period  $t$  so this all these values will be same as long as we have the we are covering the whole period  $T$ .

(Refer Slide Time: 12:19)

2. If a function is integrable on any interval of length  $T$ , then it is integrable on any other intervals of the same length and the value of the integral is the same, that is,

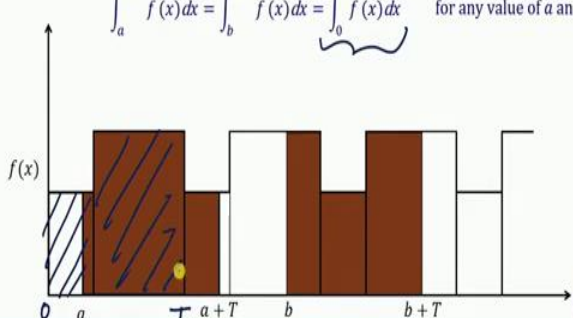

$$\int_a^{a+T} f(x) dx = \int_b^{b+T} f(x) dx = \int_0^T f(x) dx \quad \text{for any value of } a \text{ and } b$$

$f(x)$

$a$   $a+T$   $b$   $b+T$

NPTEL IIT Kharagpur

2. If a function is integrable on any interval of length  $T$ , then it is integrable on any other intervals of the same length and the value of the integral is the same, that is,

$$\int_a^{a+T} f(x) dx = \int_b^{b+T} f(x) dx = \int_0^T f(x) dx \quad \text{for any value of } a \text{ and } b$$

$f(x)$

$0$   $a$   $T$   $a+T$   $b$   $b+T$

NPTEL IIT Kharagpur

2. If a function is integrable on any interval of length  $T$ , then it is integrable on any other intervals of the same length and the value of the integral is the same, that is,

$$\int_a^{a+T} f(x) dx = \int_b^{b+T} f(x) dx = \int_0^T f(x) dx \quad \text{for any value of } a \text{ and } b$$

This can be visualized from this figure so if we are integrating suppose this is a periodic function here from here to this then we have this here and then again this starts from here and so on. So, it is a periodic function so from here to here that period ends this point to this point there is a period.

So, if we integrate this  $a$  to  $a + t$  so what is interesting here if we started at this point  $a$  and then covering this period  $t$ . So, whatever portion was left here we have covered actually here and this  $a$  plus this  $t$  so the area under this curve  $f(x)$  is going to be the area of these 2 rectangles. So, one this one and the other one is this one, so and either we start from other point this  $b$  the same situation whatever we have left here for instance its covered here.

So, ultimately in any case whether we are integrating from  $a$  to  $a + t$  or  $b$  to  $b + t$  the area of these 2 rectangles the smaller one and this bigger 1 is covered. Which is same as if we integrate from 0 to for instance  $t$  again this the area of this 2 rectangles will be covered. So, that is the interesting property that whenever we have this periodic function we can integrate from any point to that point plus the period  $t$   $b$  to  $b + t$  or from 0 to 0 plus  $t$ . So, from any point we can start and then cover the whole period that will be the all those integrals will be equal.

(Refer Slide Time: 14:11)

**Trigonometric Polynomials and Series**

- Trigonometric polynomial of order  $n$  is defined as

$$S_n(x) = a_0 + \sum_{k=1}^n \left( a_k \cos \frac{\pi kx}{l} + b_k \sin \frac{\pi kx}{l} \right)$$

NPTEL IIT Kharagpur

**Trigonometric Polynomials and Series**

- Trigonometric polynomial of order  $n$  is defined as

$$S_n(x) = a_0 + \sum_{k=1}^n \left( a_k \cos \frac{\pi kx}{l} + b_k \sin \frac{\pi kx}{l} \right)$$

Period of  $S_n(x)$  = common period of  $\left( \cos \frac{\pi x}{l}, \sin \frac{\pi x}{l}, \cos \frac{2\pi x}{l}, \dots, \sin \frac{n\pi x}{l}, \cos \frac{n\pi x}{l} \right)$

NPTEL IIT Kharagpur

So, what are the trigonometric polynomials and then trigonometric series will be considering now, so the trigonometric polynomial of order  $n$  is defined as this some constant and then sum of the cosine and the sine functions with again some coefficient here sitting in front of cosine and sine. So, and since there are  $n$  such terms are added for having this cosine and sine terms, so we call this trigonometric polynomial of order  $n$ . And the period of this polynomial which we are denoting as  $S_n(x)$  will be the common period again of all these sine and cosine.

Because here what we are doing? We are adding the cosine sin cosine sine functions, and the common period if you want to see for this finite sum in this case, will be the common period of all these functions which are being added here to construct this such a so called the trigonometric polynomial. So, the first here when the k is 1 it is a  $\cos \frac{\pi x}{l}$   $\sin \frac{\pi x}{l}$  then we have  $\cos \frac{2\pi x}{l}$   $\sin \frac{2\pi x}{l}$  and so on. This is continue until we got this  $\sin \frac{n\pi x}{l}$  and  $\cos \frac{n\pi x}{l}$ .

So, if you want to get the common period of this remember from the particular simple example the common period was coming with this the first function itself because here we have two times here and three times n times, so the period of those functions will be smaller, the largest will be from the coming from the first function and others are just the multiple. The other period we can multiply by natural number to get this period.

So, that is going to be the common period, so common period will be  $2\pi$  and then we have to divide by this  $\pi$  by  $l$  number this number  $\pi$  by  $l$  so the  $2l$ .

(Refer Slide Time: 16:27)

**Trigonometric Polynomials and Series**

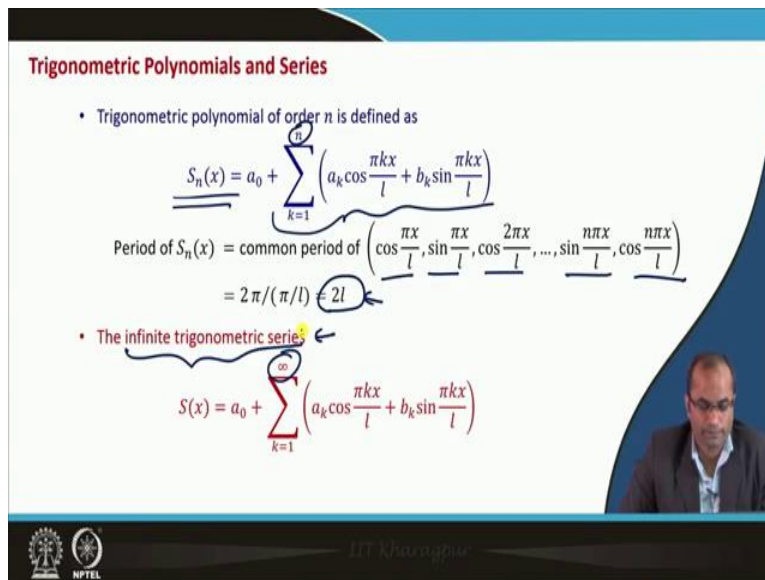

- Trigonometric polynomial of order  $n$  is defined as

$$S_n(x) = a_0 + \sum_{k=1}^n \left( a_k \cos \frac{\pi k x}{l} + b_k \sin \frac{\pi k x}{l} \right)$$

Period of  $S_n(x)$  = common period of  $\left( \cos \frac{\pi x}{l}, \sin \frac{\pi x}{l}, \cos \frac{2\pi x}{l}, \dots, \sin \frac{n\pi x}{l}, \cos \frac{n\pi x}{l} \right)$

$$= 2\pi / (\pi/l) = 2l$$

- The infinite trigonometric series

$$S(x) = a_0 + \sum_{k=1}^{\infty} \left( a_k \cos \frac{\pi k x}{l} + b_k \sin \frac{\pi k x}{l} \right)$$

**Trigonometric Polynomials and Series**

- Trigonometric polynomial of order  $n$  is defined as
 
$$S_n(x) = a_0 + \sum_{k=1}^n \left( a_k \cos \frac{\pi k x}{l} + b_k \sin \frac{\pi k x}{l} \right)$$
- Period of  $S_n(x)$  = common period of  $\left( \cos \frac{\pi x}{l}, \sin \frac{\pi x}{l}, \cos \frac{2\pi x}{l}, \dots, \sin \frac{n\pi x}{l}, \cos \frac{n\pi x}{l} \right)$ 

$$= 2\pi / (\pi/l) = 2l$$
- The infinite trigonometric series
 
$$S(x) = a_0 + \sum_{k=1}^{\infty} \left( a_k \cos \frac{\pi k x}{l} + b_k \sin \frac{\pi k x}{l} \right)$$

if it converges, also represents a function of period  $2l$ .

So, for this trigonometric polynomial which is just the edition of all these functions whose common period is  $2l$ . So, the period for this  $S_n x$  for this function here for this polynomial will be 2 times  $l$ . And the trigonometric series we call the infinite so infinite trigonometric series when the  $k$  goes from 1 to infinity, so instead of this  $n$  if we are going for infinitely many terms we call this infinite trigonometric series. And in this case if the series converges and this is another interesting point that if this series converges, because now we are talking about infinite series and the series may not converge.

But if this converges in that case if it converges this also represents a function of period  $2l$ . Because for this when  $n$  is finite we have seen that the period of this  $2n$  or  $S_n x$  is  $2l$ . And now here we are keep on adding these terms but that common period will not change that will remain  $2l$  itself. So, if this series converges then that function to whom this is converging that will be a  $2l$  periodic function.

So, that is another information which we need here for explaining the Fourier series, in the next lecture indeed. So, here we are we have now introduce in this trigonometric series or infinite trigonometric series and the trigonometric polynomial in terms of the cosine and sine functions.

(Refer Slide Time: 18:14)

**Remark** Though sine and cosine functions are quite simple in nature but their sum function may be quite complex.

plot of  $\sin x + \sin 2x + \cos 3x$

The slide features a blue header and footer. The footer contains the logos of IIT Kharagpur and NPTEL, along with the text 'IIT Kharagpur'.

So, just a remark so though this sine and the cosine functions are just very simple functions and we know the graph of each of them. But what is interesting that they are some may be quite complex and I just want to clear this point because later on we will see that many many complicated functions can be represented in terms of this sine and cosine functions.

Just a simple example if we take which we have just seen before  $\sin x + \sin 2x + \cos 3x$  for instance if we take this function whose period is going to be  $2\pi$ , if the common period of all these functions here is  $2\pi$ , so the period of this function the sum function is  $2\pi$ .

(Refer Slide Time: 19:02)

**Remark** Though sine and cosine functions are quite simple in nature but their sum function may be quite complex.

plot of  $\sin x + \sin 2x + \cos 3x$

The function has a period  $2\pi$  which is a common period of  $\sin x$ ,  $\sin 2x$ ,  $\cos 3x$ .

IIT Kharagpur

So, if we just plot this, what will happen? We can see this is not as simple as we perhaps expected from the sine and the cosine functions. So, here for instance if we say this starts from 0 then it is having this curvature here and then goes up to this up to this  $2\pi$  and then again this repeats its value. So, this is in one period the function starts from here and continue up to this point, and then it repeats its value, so from here to this point it is one period covering one period it is a  $2\pi$ . So, at this point here we are somewhere  $2\pi$  and then it will repeat its value.

So, this sum of these three just three simple functions represents this complicated behavior then we can imagine that we have if we have possibility of having many more terms or infinitely many terms that too with some coefficients here setting with this cos and sine. So, we have a full

flexibility of getting a desired function in terms of the sine and the cosine functions and that is what we will exactly do in the Fourier series, in the next lecture we will observe that. So, the function has this period  $2\pi$  which is a common period of all these three functions which I have already discussed.

(Refer Slide Time: 20:40)

**Orthogonality Property of Trigonometric System**

We call two functions  $\phi(x)$  and  $\psi(x)$  to be orthogonal on the interval  $[a, b]$  if

$$\int_a^b \phi(x)\psi(x)dx = 0$$

IIT Kharagpur  
NPTEL

**Orthogonality Property of Trigonometric System**

We call two functions  $\phi(x)$  and  $\psi(x)$  to be orthogonal on the interval  $[a, b]$  if

$$\int_a^b \phi(x)\psi(x)dx = 0$$

**Lemma:** The basic trigonometric system  $1, \cos x, \sin x, \cos 2x, \sin 2x, \dots$  is orthogonal on the interval  $[-\pi, \pi]$  or  $[0, 2\pi]$

*Handwritten notes:*  $1, \cos x, \sin x, \cos 2x, \sin 2x, \dots$  (circled)  $2\pi$   $[a, a+2\pi]$

IIT Kharagpur  
NPTEL

**Orthogonality Property of Trigonometric System**

We call two functions  $\phi(x)$  and  $\psi(x)$  to be orthogonal on the interval  $[a, b]$  if

$$\int_a^b \phi(x)\psi(x)dx = 0$$

Lemma: The basic trigonometric system

$1, \cos x, \sin x, \cos 2x, \sin 2x, \dots$

is orthogonal on the interval  $[-\pi, \pi]$  or  $[0, 2\pi]$

And very interesting property now we will look into for trigonometric system. So, what is the trigonometric system? We are calling this sine cosine and so on  $\sin 2x \cos 3x$ , that is system with having cosine sine functions and that is called trigonometric system. So, we call that two functions  $\phi(x)$  and  $\psi(x)$  to be orthogonal on this interval  $a, b$ , if we integrate from  $a$  to  $b$  the product of these two functions and if it is 0, if the product of the two functions integrated over the certain interval here  $a, b$  is 0 then we call that these two functions are orthogonal in this interval  $a, b$  or on the interval  $a, b$  if this integral is 0.

So, now we have the result for our trigonometric system, so the basic trigonometric system we call the basic trigonometric system and we have the simple functions  $1 \cos x \sin x$  we have  $\cos 2x \sin 2x$  etcetera and this can continue to whatever number we want. So, this basic trigonometric function what is interesting here and we will prove this fact that this is orthogonal on this interval minus  $\pi$  to  $\pi$  or we can take any other interval for instance  $0$  to  $2\pi$  or  $a$  to  $a + 2\pi$  as long as we are covering the length this  $2\pi$  than for because this is the common period for this is  $2\pi$  for this system here.

So, this is orthogonal on the interval minus  $\pi$  to  $\pi$  or  $0$  to  $2\pi$  or any number  $a$  we can take and  $a + 2\pi$  this is also fine. So, this is we will observe that this basic trigonometric system this is orthogonal, what do we mean? If we take any two functions from this system, for instance, we take  $1$ , we take  $\cos 2x$  and  $1$  into  $\cos 2x$  and then integrate from this minus  $\pi$  to  $\pi$   $dx$ . This must be 0. This is clearly visible here too but we will formally prove in the next slide.

So, if we take any two members from this of this family any two members form this system and their product when integrated over this interval minus pi to pi, the value of this integral is going to be 0. This is what we will observe now.

(Refer Slide Time: 23:19)

For any integer  $n \neq 0$ : We have the following integrals to show the orthogonality of the function 1 with any member of sine or cosine family

1.

For any integer  $n \neq 0$ : We have the following integrals to show the orthogonality of the function 1 with any member of sine or cosine family

$$\int_{-\pi}^{\pi} 1 \cdot \cos(nx) dx = \frac{\sin(nx)}{n} \Big|_{-\pi}^{\pi} = 0$$

$$\int_{-\pi}^{\pi} 1 \cdot \sin(nx) dx = -\frac{\cos(nx)}{n} \Big|_{-\pi}^{\pi} = 0$$

We have also the following useful results

$$\int_{-\pi}^{\pi} \cos^2(nx) dx = \int_{-\pi}^{\pi} \frac{1 + \cos(2nx)}{2} dx$$

For any integer  $n \neq 0$ : We have the following integrals to show the orthogonality of the function 1 with any member of sine or cosine family

$$\int_{-\pi}^{\pi} 1 \cdot \cos(nx) dx = \frac{\sin(nx)}{n} \Big|_{-\pi}^{\pi} = 0$$

$$\int_{-\pi}^{\pi} 1 \cdot \sin(nx) dx = -\frac{\cos(nx)}{n} \Big|_{-\pi}^{\pi} = 0$$

We have also the following useful results

$$\int_{-\pi}^{\pi} \cos^2(nx) dx = \int_{-\pi}^{\pi} \frac{1 + \cos(2nx)}{2} dx = \pi$$

Handwritten notes on the right side of the slide show the derivation of the second integral:  $\frac{1}{2} \int_{-\pi}^{\pi} dx + \frac{1}{2} \int_{-\pi}^{\pi} \cos(2nx) dx$ . The first term is  $\frac{1}{2} \cdot 2\pi = \pi$  and the second term is 0.

NPTEL

So, we will consider different cases, first we are considering here that if  $n$  is not equal to 0 its integer we are talking about, but which is not equal to 0. And then we have the following integrals to show the orthogonality of the function 1 with any other member of the sine or cosine family. So, at first what we are looking for.

So, 1 is also a member of this trigonometric system, so this 1 and we will take with any other sine or cosine function, either  $\sin x$ ,  $\sin 2x$ ,  $\cos x$ ,  $\cos 2x$  etcetera. And we will show here that these two are orthogonal 1 with any other trigonometric any other member of this trigonometric system from the sine or cosine family. So, here if we take 1 and for instance, is  $\cos nx$ ,  $n$  could be anything other than 0 because if  $n$  is 0 this is going to be 1, so which that the same member we will be making the product so that we are avoiding here the two different members.

So, this is one member and this is the another member of the of this trigonometric system and if we integrate from minus pi to pi, so it is just the product is  $\cos nx$  so the integral will be  $\sin nx$  over  $n$  and then minus pi to pi.  $\sin n\pi$  is 0,  $\sin$  minus  $n\pi$  is also 0 so the result of this is 0. So, here we have seen that with 1 if we take any member of the cosine family that means the  $\cos x$ ,  $\cos 2x$ ,  $\cos 3x$ ,  $\cos 5x$  etcetera, these two are orthogonal.

Similarly we can also prove that with 1 if we take any other member of this sine family from our trigonometric system, then again we can see that this is  $\cos nx$  over  $n$  and here or indeed from here directly we can so  $\sin nx$  is a odd function and the value is 0. So, the value of this integral is also 0.

So, this at least we have seen that with 1 we can take any member of the cosine family or any member of the sine family and these are orthogonal. We can also check this following useful results that if we take the same member that means the  $\cos nx$ ,  $\cos nx$  mean  $\cos x$ ,  $\cos x$  or  $\cos 2x$  with  $\cos 2x$ , so they are not different members, so they are the same members.

What we have said in the earlier result that, the system is orthogonal that means any two different members if we take they are orthogonal but not the same member. So, here we are taking the same member we have taken the  $\cos nx$  and with  $\cos nx$  for same  $n$  of course. So, if we have taken the same member in that case this is not 0 and we will observe now that what is the value coming. So, this  $\cos^2 nx$  we can convert into this two angle double angle  $2nx$ .

So,  $1 + \cos 2nx$  by 2 with the trigonometric identity we have this result. And then this value is coming to be  $\pi$ , how  $\pi$ ? So, the first integral is this half is integral minus  $\pi$  to  $\pi$  and the  $dx$ , so here is  $dx$  missing  $dx$ . So, and the second one so the plus again half we have minus  $\pi$  to  $\pi$  and we have  $\cos$  or  $2nx$  and  $dx$ . So, this  $\cos 2nx dx$  we have just seen above that this is going to be 0 with any number  $nx$  there, so this integral is 0, whereas the first one gives half and this is  $2\pi$ . So, we get the  $\pi$  as a value  $\pi$  there.

(Refer Slide Time: 27:30)

For any integer  $n \neq 0$ : We have the following integrals to show the orthogonality of the function 1 with any member of sine or cosine family

$$\int_{-\pi}^{\pi} 1 \cdot \cos(nx) dx = \frac{\sin(nx)}{n} \Big|_{-\pi}^{\pi} = 0$$

$$\int_{-\pi}^{\pi} 1 \cdot \sin(nx) dx = -\frac{\cos(nx)}{n} \Big|_{-\pi}^{\pi} = 0$$

We have also the following useful results

$$\int_{-\pi}^{\pi} \cos^2(nx) dx = \int_{-\pi}^{\pi} \frac{1 + \cos(2nx)}{2} dx = \pi$$

$$\int_{-\pi}^{\pi} \sin^2(nx) dx = \int_{-\pi}^{\pi} \frac{1 - \cos(2nx)}{2} dx = \pi$$

DT Kharagpur

So, here we have the value  $\pi$  so  $\cos^2 nx dx$  is equal to this one and is equal to  $\pi$ . So, when we take the same member of the family than the value is  $\pi$ . Similarly, if we take the  $\sin$  from the sine family the same member  $\sin nx \sin nx$ . In this case also we can observe that this is  $1 - \cos$

$\cos nx$  by 2 and again the second integral will lead to 0 and this half integral minus  $\pi$  to  $\pi$  will give us  $\pi$ .

So, here the value is  $\pi$  in either case the only member left is 1, if we take 1 with 1 and then integrate from  $-\pi$  to  $\pi$   $dx$ , in this case the value will be  $2\pi$  naturally. So, these are three situations we have covered, one when we have taken the same member from the  $\cos$  family value is  $\pi$ , the same member from the  $\sin$  family again the value is  $\pi$ , and the same member of this 1 itself, because 1 is also a member of the trigonometric system in that case this is  $2\pi$ .

And 1 with any other member of the  $\cos$  is 0, 1 with any other member of the  $\sin$  it is 0. And there is a now something left here to be proved that any two members we can take of the different two members of the family it is a 0. So, here we have only proved that with the 1 if we take any other member from the system it is 0.

(Refer Slide Time: 28:58)

For any integer  $m$  and  $n$  ( $m \neq n$ ): Now we show that any two different members of the same family (sine or cosine) are orthogonal.

For the cosine family, we have

$$\int_{-\pi}^{\pi} \cos(nx)\cos(mx)dx$$

The slide also features a small inset video of a man in a suit and glasses, likely the lecturer, in the bottom right corner. At the bottom of the slide, there are logos for IIT Kharagpur and NPTEL.

For any integer  $m$  and  $n$  ( $m \neq n$ ): Now we show that any two different members of the same family (sine or cosine) are orthogonal.

For the cosine family, we have

$$\int_{-\pi}^{\pi} \cos(nx)\cos(mx)dx = \frac{1}{2} \int_{-\pi}^{\pi} [\cos(n+m)x + \cos(n-m)x] dx = 0$$

For the sine family, we have

$$\int_{-\pi}^{\pi} \sin(nx)\sin(mx)dx = \frac{1}{2} \int_{-\pi}^{\pi} [\cos(n-m)x - \cos(n+m)x] dx = 0$$

So, now we will continue this proof. So, we will take now for any integer  $m$  and  $n$ , when these two are not equal that means first for the cosine family we will take. So,  $\cos nx$  and  $\cos mx$ , so when  $m$  and  $n$  are equal we have seen the value is  $\pi$ . So, but now we have two different members, one is  $\cos nx$  another one is  $\cos mx$ , when  $n$  and  $m$  are not equal. So they are different member of the family.

So, in this case we again use the trigonometric identity  $2 \cos a \cos b$  with half here, so  $\cos$  this  $n$  plus  $m$  and then  $n$  minus  $m$  and integral is from minus  $\pi$  to  $\pi$ . So, here the  $\sin$  will come and we integrate here also  $\sin$  will come and then with  $\pi$  and minus  $\pi$ , in either case the value is going to be 0.

So, can when we take the two different member of the cosine family the value is 0, similarly if we take from the sine family also the same situation will happen so again this trigonometric identity will lead to the  $\cos$  only with the negative sign there and when we integrate this again  $\sin n$  minus  $m$   $\sin n$  plus  $m$  will come and  $x$  and when we have to substitute the value  $\pi$   $n$  minus  $\pi$  so  $\sin$  integer times  $\pi$  is 0 and  $\sin n$  integer times  $\pi$  is 0.

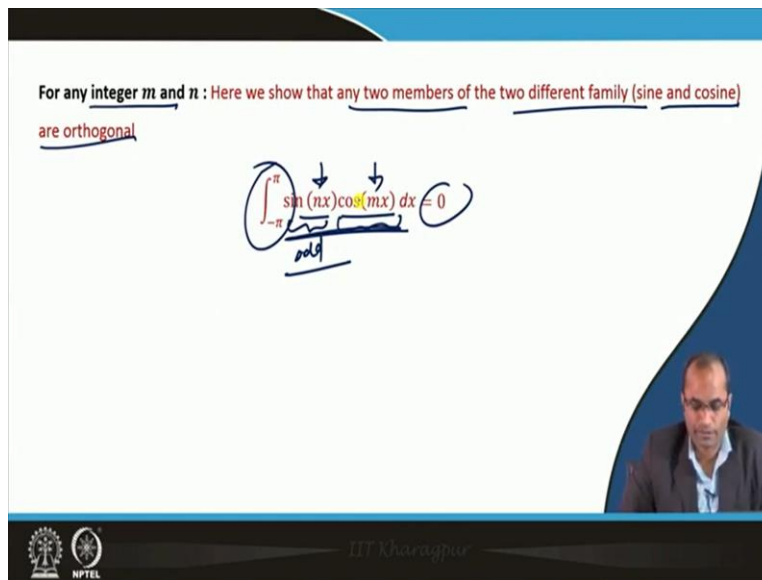

So, this will also lead to 0, so we have also seen that if we take two different members from the same family it is going to be 0, if we take fix 1 as a member and take any other member from the cosine or from the sine that is 0, so what is left now? That for any  $m, n$  if we take 1 member from sine family other member from the cosine family then what will happen?

(Refer Slide Time: 30:57)

For any integer  $m$  and  $n$  : Here we show that any two members of the two different family (sine and cosine) are orthogonal

$$\int_{-\pi}^{\pi} \sin(nx) \cos(mx) dx = 0$$

odd

The slide features a white background with a blue header and footer. The text at the top states: "For any integer m and n : Here we show that any two members of the two different family (sine and cosine) are orthogonal". Below this, a handwritten integral equation is shown:  $\int_{-\pi}^{\pi} \sin(nx) \cos(mx) dx = 0$ . The word "odd" is written below the integral. In the bottom right corner, there is a small inset video of a man with glasses and a dark jacket. The footer contains the NPTEL logo and the text "IIT Kharagpur".

So, for any integer  $m$  and  $n$  we will show now that any two members of the two different family means sine and cosine they are also orthogonal, so we take  $\sin nx$  and then the  $\cos mx$ , the two here the two members the two different members, so one from sine and other from cosine. So, here  $m$  and  $n$  may be the same because the family is different, one is coming from sine another one is coming from cosine.

So, we can talk about  $\sin x \cos x$  so that value will be also 0, and here the reasoning is very clear he  $\cos$  is the even function here  $\sin$  is the odd function and when we integrate minus  $\pi$  to  $\pi$  this integrant is odd, so the value is 0 irrespective of whatever  $n$  or  $m$  is.

(Refer Slide Time: 31:45)

For any integer  $m$  and  $n$  : Here we show that any two members of the two different family (sine and cosine) are orthogonal

$$\int_{-\pi}^{\pi} \sin(nx)\cos(mx) dx = 0$$

**Theorem:** The trigonometric system

$$1, \cos \frac{\pi x}{l}, \sin \frac{\pi x}{l}, \cos \frac{2\pi x}{l}, \sin \frac{2\pi x}{l}, \dots$$

is orthogonal on the interval  $[-l, l]$  or  $[a, a + 2l]$ , where  $a$  is any real number.

*Handwritten note: } Period 2l*

For any integer  $m$  and  $n$  : Here we show that any two members of the two different family (sine and cosine) are orthogonal

$$\int_{-\pi}^{\pi} \sin(nx)\cos(mx) dx = 0$$

**Theorem:** The trigonometric system

$$1, \cos \frac{\pi x}{l}, \sin \frac{\pi x}{l}, \cos \frac{2\pi x}{l}, \sin \frac{2\pi x}{l}, \dots$$

is orthogonal on the interval  $[-l, l]$  or  $[a, a + 2l]$ , where  $a$  is any real number.

So, the theorem, what is we have a more general result than what we have just proved where we have taken the basic the fundamental trigonometric system where the period was  $2\pi$ . But for a rather general trigonometric system where the period is not  $2\pi$  but it is  $2l$ , we can also prove the same similar result that this trigonometric system and now we have generalize the system. So, we have taken  $1$  and  $\cos \pi x$  over  $l$ ,  $\sin \pi x$  over  $l$ ,  $\cos 2\pi x$  over  $l$ ,  $\sin 2\pi x$  over  $l$  and then we will continue with  $\cos 3\pi x$  over  $l$ ,  $\sin 3\pi x$  over  $l$ , etcetera. So, here this trigonometric system the period is period is  $2l$  now instead of  $2\pi$ .

So, in this case, this is orthogonal in on the interval minus l to l, if we go from minus l to l we are covering the period 2l or a to a plus 2l we can go, where a is any real number. So, this trigonometric system is also orthogonal in these intervals minus l to l or a to a plus 2l. So, this is a more general result than the earlier one which we have proved, so this we are not proving but exactly the proof follows the similar argument what we have just done there.

(Refer Slide Time: 33:10)

The common period of the trigonometric system  $1, \cos \frac{\pi x}{l}, \sin \frac{\pi x}{l}, \cos \frac{2\pi x}{l}, \sin \frac{2\pi x}{l}, \dots$  is  $2l$

$$\int_{-l}^l \cos \frac{m\pi x}{l} \cos \frac{n\pi x}{l} dx = \int_a^{a+2l} \cos \frac{m\pi x}{l} \cos \frac{n\pi x}{l} dx = \begin{cases} 0 & \text{if } m \neq n \\ l & \text{if } m = n \neq 0 \end{cases}$$

$$\int_{-l}^l \sin \frac{m\pi x}{l} \sin \frac{n\pi x}{l} dx = \int_a^{a+2l} \sin \frac{m\pi x}{l} \sin \frac{n\pi x}{l} dx = \begin{cases} 0 & \text{if } m \neq n \\ l & \text{if } m = n \neq 0 \end{cases}$$

$$\int_{-l}^l \sin \frac{m\pi x}{l} \cos \frac{n\pi x}{l} dx = \int_a^{a+2l} \sin \frac{m\pi x}{l} \cos \frac{n\pi x}{l} dx$$

So, the common period of this trigonometric system is the 2l, this can be easily obtained from the period of this first two functions which is 2l. So, and what results we have now it is if minus l to l we integrate the cos mx and the cos nx so for different m and n than the value will be 0. And if have same m and n then the value will be l earlier it was pi. So, if m is not equal to n the value is 0 so they are orthogonal if they are two different members but if they are the same members then the value is l, this is the result can be proved.

Or minus l to l sin for the sine family also we have the same result that it is 0 when they are two different members of the family and if they are the same then the value is coming as l. And we can we know already for periodic function where are you integrate from minus l to l or from a to a plus 2l, the value will be the same. Another result that we can have two different members now sine and cosine, one from sine family another from cosine family. And then we will observe that this is also 0. So, this is a very important result which will be used in the next lecture.

(Refer Slide Time: 34:40)

The trigonometric system  $1, \cos \frac{\pi x}{l}, \sin \frac{\pi x}{l}, \cos \frac{2\pi x}{l}, \sin \frac{2\pi x}{l}, \dots$

For  $l = \pi$ , it reduces to the standard trigonometric system of common period  $2\pi$

$1, \cos x, \sin x, \cos 2x, \sin 2x, \dots$

The value of the integral over length of period of integrand is equal to zero if the integrand is a product of two different members of trigonometric system.

If the integrand is product of two same member from sine or cosine family then the value of the integral is half of the interval length on which the integral is performed.

Dr. D.T. Kharasiga

NPTEL

So, what we have now this remark, so if  $l$  is equal to  $\pi$  this system reduces to so if we put  $l$  is equal to  $\pi$ , so it is simply that system which we have discuss before  $1, \cos x, \sin x, \sin 2x$ , etcetera. So, this is the same system the standard trigonometric system of  $2\pi$ , this one which can be just obtained from this one. And the value of the integral so which was the earlier result which we have just discussed then, over the length of the period of integrand is equal to 0, if the integrand is a product of two different members of the trigonometric systems.

And if the product is from the same member from the sine or the cosine family. So we are taking  $\sin x \sin x$  or  $\sin 2x \sin 2x$ , in that case it is the value is the half of the interval length. So, if we are talking about minus 1 to 1 so the value will be 1 or we are talking about minus  $\pi$  to  $\pi$  the value will be  $\pi$ , this is what we have seen.

## CONCLUSION

Trigonometric Polynomial:  $S_n(x) = a_0 + \sum_{k=1}^n \left( a_k \cos \frac{\pi k x}{l} + b_k \sin \frac{\pi k x}{l} \right)$

The Trigonometric System:  $1, \cos \frac{\pi x}{l}, \sin \frac{\pi x}{l}, \cos \frac{2\pi x}{l}, \sin \frac{2\pi x}{l}, \dots$

Orthogonal on the interval  $[-l, l]$

And just to conclude, so we have basically discussed that trigonometric polynomial today which is this finite sum of the cos and the sine function, and we have also discussed that trigonometric system which is  $1, \cos \pi x, \sin \pi x$  over  $l$ , and so on. And the interesting property of this trigonometric system which we have also proved it is that.

The system is orthogonal on this interval minus 1 to 1, that means any two members we take and the product if we integrate over minus 1 to 1 the value will be 0. So, you can take any two different members here and the product if integrated over from minus 1 to 1 the value will be 0. So, that is all for this lecture and I thank you for your attention.
