**Professor Jithendra Kumar**  
**Department of Mathematics**  
**Indian Institute of Technology Kharagpur**  
**Lecture 36**  
**Fourier Series for Even and Odd Functions**

So welcome back to lectures on Engineering Mathematics II. And this is lecture number 36 on Fourier Series for even and odd functions. So in this lecture we will first discuss what are the even and odd functions, again. And then the evaluation of the Fourier coefficients and hence the Fourier Series for even and odd function.

We have already discussed in one of the earlier lectures that, if the function, the given function is even or odd then the corresponding Fourier Series becomes simpler. So it will have either only sine terms or cosine terms.

(Refer Slide Time: 00:54)

**Even and Odd Functions:** A function is said to be

an even about the point  $a$  if  $f(a-x) = f(a+x)$  for all  $x$   $f(-x) = f(x)$

and odd about the point  $a$  if  $f(a-x) = -f(a+x)$  for all  $x$   $f(-x) = -f(x)$

⇒ The product of two even or two odd functions is again an even function.

⇒ The product of an even function and an odd function is an odd function.

IIT Kharagpur

NPTEL

So now coming to the even and odd functions. So a function is said to be an even, an even function about the point  $a$  if we have this condition that if  $a$  minus  $x$  is equal to  $f$   $a$  plus  $x$  for all  $x$ . Then we call that the function is an even function. On the other hand we will call the function an odd function about the point  $a$ , if  $f$   $a$  minus  $x$  is equal to minus  $f$   $a$  plus  $x$  and that is for all  $x$ . So that is the odd function.

So usually when we, in many examples we will see that this  $a$  is just 0. So what we have that  $f$  minus  $x$  is equal to  $f x$  for even function and  $f$  minus  $x$  is equal to minus  $f x$  for odd functions, when  $a$  is 0. So when we are talking about  $x$  equal to 0, so the  $y$  axis. So there is a property of this even and odd function so the product of two even or two odd functions is again an even function, because of that minus sign. So minus if multiplied by minus is again plus.

So this property holds for if we take 2 even functions, their product will be also even. Or if we take 2 odd functions their product will be also an odd function. So that property exactly will be used for evaluating Fourier coefficients. And moreover the product of an even function and an odd function, so if we have in the product one function is even and the other one is odd, in that case the product will be again an odd function. So having these properties of even and odd functions we will now evaluate or simplify the Fourier coefficients for such functions.

(Refer Slide Time: 3:10)

Evaluation of Fourier Coefficients for Even and Odd Functions

$$a_n = \frac{1}{\pi} \int_{-\pi}^{\pi} f(x) \cos(nx) dx = \frac{2}{\pi} \begin{cases} \int_0^{\pi} f(x) \cos(nx) dx, & \text{when } f \text{ is even function about } 0 \\ 0, & \text{when } f \text{ is odd function about } 0 \end{cases}$$

$$b_n = \frac{1}{\pi} \int_{-\pi}^{\pi} f(x) \sin(nx) dx = \frac{2}{\pi} \begin{cases} 0, & \text{when } f \text{ is even function about } 0 \\ \int_0^{\pi} f(x) \sin(nx) dx, & \text{when } f \text{ is odd function about } 0 \end{cases}$$

So suppose we have this an given by this integral  $\frac{1}{\pi} \int_{-\pi}^{\pi} f(x) \cos nx dx$ . Just for simplicity again we are considering this minus  $\pi$  to  $\pi$ . But we can also talk about minus  $L$  to  $L$  and then  $\cos n \pi x$  over  $L$  and the outside term will be  $1$  over  $L$ . So just for simplicity we are talking about the interval minus  $\pi$  to  $\pi$ .

So if this function  $f(x)$  is an even function, so what will happen the  $\cos$  is an even function, so the  $\cos$  here is even. And if this function  $f(x)$  is even function then the product is again even. And in

that case the integrand here the whole integrand is an even function. So minus pi to pi this integral can be written as integral 0 to pi and then 2 times. So the 2 over pi will come outside. And then we have this integral for when f is even.

And if f is odd, so if f is odd and then we have even, so the product is again odd and in that case since the integral is minus pi to pi, then this will be 0. So if f is an odd function about zero this integral will become zero, meaning the ans will become 0. And if f is an even function, then those an we can simply compute with the help of this rather simplified integral. So now integral is varying from 0 to pi only instead of minus pi to pi.

Now similar situation happens for  $b_n$  as well, so if this  $f(x)$  is even for instance and the corresponding sine is an odd here. So the integrand is odd and in that case this integral will become zero. So when f is even the integral for  $b_n$  or the coefficients, the Fourier coefficients  $b_n$ s will become zero. And the other one will be simplified the 2 time and then 0 to pi  $f(x) \sin nx$  dx.

So what we have here that if a function is odd or the function is even, then the corresponding Fourier Series either will have only the  $b_n$ s terms or it will have only the  $a_n$ s terms. So when f is even we will get only the  $a_n$ s, the coefficient  $a_n$ s, and when f is odd we will get the coefficients  $b_n$ . And the correspondingly the Fourier Series will be simplified because in case of the even when we have only the  $a_n$ s there, so we have only the cos term in the Fourier Series and when the function is an odd function.

So we will have only  $b_n$ s there. And hence the Fourier Series contain only sine terms. So that is this simplification for even and odd functions, we are going to discuss now in context of the Fourier Series.

(Refer Slide Time: 6:40)

Assume that  $f$  is a piecewise continuous function on  $[-\pi, \pi]$ . Then

a) If  $f$  is an even function then the Fourier series takes the simple form

$$f(x) \sim \frac{a_0}{2} + \sum_{n=1}^{\infty} a_n \cos(nx) \quad a_n = \frac{2}{\pi} \int_0^{\pi} f(x) \cos(nx) dx, \quad n = 0, 1, 2, \dots$$

Such a series is called a **cosine series**.

b) If  $f$  is an odd function then the Fourier series of  $f$  has the form

$$f(x) \sim \sum_{n=1}^{\infty} b_n \sin(nx) \quad b_n = \frac{2}{\pi} \int_0^{\pi} f(x) \sin(nx) dx, \quad n = 1, 2, \dots$$

So we assume that  $f$  is a piecewise continuous function on this interval minus  $\pi$  to  $\pi$ . Again for simplicity we are taking minus  $\pi$  to  $\pi$ . All these results can be extended for a general interval minus  $L$  to  $L$ . So in that case if  $f$  is an even function then the Fourier Series takes the following simple form. So if it is an even function we have only the  $a_n$  and the Fourier coefficient  $a_n$  will survive the  $b_n$  will become zero.

And therefore in the Fourier Series we will see only the  $\cos$  term. So the Fourier Series will be simplified to this  $a_n$  by 2 and having only the cosine terms, where this  $a_n$  can be computed with this integral  $2$  over  $\pi$ ,  $0$  to  $\pi$   $f(x) \cos nx dx$ . And such a series is called cosine series because we have only the cosine terms in the series and therefore we call such a series as cosine series.

If  $f$  is an odd function, so if  $f$  is an odd function then the Fourier Series will be simplified again and since this  $f$  is odd the  $b_n$  will survive, all  $a_n$  will become zero. That means in Fourier Series we will have only the sine terms, that means  $n$  goes  $1$  to infinity and  $b_n \sin nx$  will be the Fourier Series. And the  $b_n$  we can compute with this help of other simplified formula, with where the integral goes from  $0$  to  $\pi$  and there is a factor  $2$  there. So  $2$  over  $\pi$ ,  $0$  to  $\pi$  and  $f(x) \sin nx dx$ .

(Refer Slide Time: 8:09)

Assume that  $f$  is a piecewise continuous function on  $[-\pi, \pi]$ . Then

a) If  $f$  is an even function then the Fourier series takes the simple form

$$f(x) \sim \frac{a_0}{2} + \sum_{n=1}^{\infty} a_n \cos\left(\frac{n\pi x}{L}\right) \quad a_n = \frac{2}{L} \int_0^L f(x) \cos\left(\frac{n\pi x}{L}\right) dx, \quad n = 0, 1, 2, \dots$$

Such a series is called a cosine series.

b) If  $f$  is an odd function then the Fourier series of  $f$  has the form

$$f(x) \sim \sum_{n=1}^{\infty} b_n \sin\left(\frac{n\pi x}{L}\right) \quad b_n = \frac{2}{L} \int_0^L f(x) \sin\left(\frac{n\pi x}{L}\right) dx, \quad n = 1, 2, \dots$$

Such a series is called a sine series.

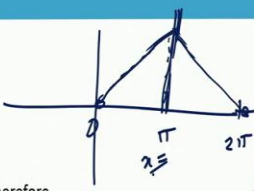

IIT Kharagpur

So these results can be also considered when we have minus L to L. For example the interval. So here this  $n\pi x$  will be simply  $n\pi x$  over L and this integral here instead of  $\pi$  we will have just L and again here  $n\pi x$  will be  $n\pi x$  over L. So this will be more general formula so again the cosine series for the sine series it will take the form, so  $n\pi x$  over L here and then the L and then we have L there. And again here for  $n\pi x$  we have  $n\pi x$  over L. So these changes will be made and then we have more general Fourier cosine or Fourier sine series for the functions which are odd and even respectively. So well such a series is called a sine series.

(Refer Slide Time: 9:06)

**Example:** Obtain the Fourier series to represent the function  $f(x)$

$$f(x) = \begin{cases} x, & \text{when } 0 \leq x \leq \pi \\ 2\pi - x, & \text{when } \pi < x \leq 2\pi \end{cases}$$

**Solution:** The given function is an even function about  $x = \pi$  and therefore

$$b_n = \frac{1}{\pi} \int_0^{2\pi} f(x) \sin(nx) dx = 0.$$

$$a_0 = \frac{1}{\pi} \int_0^{2\pi} f(x) dx = \frac{1}{\pi} \left[ \int_0^{\pi} x dx + \int_{\pi}^{2\pi} (2\pi - x) dx \right]$$

$$= \frac{1}{\pi} \left[ \frac{\pi^2}{2} + \frac{\pi^2}{2} \right] = \pi$$

Logo: IIT Kharagpur NPTEL

So now we can discuss some examples based on this simplification. So for instance we want to represent this function here  $f(x)$  which is given by  $x$  and  $2\pi$  minus  $x$  in the range  $\pi$  to  $2\pi$ . And  $x$  is in the range  $0$  to  $\pi$ . So if you look at this graph of this function  $0$  to  $\pi$ , so for instance here we have  $\pi$  and then we have  $2\pi$  there. So  $0$  to  $\pi$  it increases, linearly.

So here we have again  $\pi$ . And then from  $\pi$  to  $2\pi$ , it is  $2\pi$  minus  $x$ . So it decreases to  $0$ . So we have this function kind of head function, which is symmetrical around this  $x$  is equal to  $\pi$ . So it is, it is an even function around this  $x$  is equal to  $\pi$ . And then we can apply the result which we have discussed earlier.

So the given function is an even function about this  $x$  equal to  $\pi$ . Therefore what we can have the  $b_n$ s will be zero. So  $b_n$  we have this  $0$  to  $2\pi$  and  $1$  over this  $L$ ,  $1$  over  $L$  and  $0$  to  $2L$  and then  $f(x) \sin$  this because the period is  $2\pi$ , so  $nx$  only  $dx$ . This will be zero without any, any calculation we can just set to  $0$ , because this is an odd function around this  $\pi$ .

So the integral this  $0$  to  $2\pi$  will become zero. And then if we compute this a naught and then  $a_n$ . So a naught is  $1$  over  $\pi$ ,  $0$  to  $2\pi$   $f(x) dx$ . And we know the  $f(x)$  is  $x$  and  $2\pi$  minus  $x$  in this range. So we can compute this integral. So here we will have  $x$  square by  $2$  meaning this  $\pi$  square by  $2$

and then here we will have minus sign with 2pi minus x wholly square by 2. So again we will get pi square by 2. And as a result we are getting this pi. So a naught we have computed as pi.

(Refer Slide Time: 11:20)

$$a_n = \frac{1}{\pi} \int_0^{2\pi} f(x) \cos(nx) dx = \frac{1}{\pi} \left[ \int_0^{\pi} x \cos(nx) dx + \int_{\pi}^{2\pi} (2\pi - x) \cos(nx) dx \right]$$

$$= \frac{1}{\pi} \left[ \frac{1}{n^2} [(-1)^n - 1] - \frac{1}{n^2} [1 - (-1)^n] \right]$$

$$= \frac{1}{\pi} \left[ \frac{(-1)^n - 1}{n^2} - \frac{1 - (-1)^n}{n^2} \right]$$

$$= \frac{1}{\pi} \left[ \frac{(-1)^n - 1 - 1 + (-1)^n}{n^2} \right]$$

$$= \frac{1}{\pi} \left[ \frac{2(-1)^n - 2}{n^2} \right]$$

$$= \frac{2(-1)^n - 2}{n^2 \pi}$$

And then we can compute an as well, with the formula 1 over pi, and 0 to 2 pi and fx cos nx dx. So in this case again 0 to pi it is x and pi to 2pi it is 2pi minus x. So we can again simplify these results, which will give us, so if we can take a quick look here. So we have x and then we have sine nx over n and 0 to pi and then minus sign 0 to pi. So x the differentiation will be 1. And then we have again the sine nx over n and then dx.

So because of this sine and then we are substituting pi or 0. So this will become 0. And we have the result from here. So again with minus sine, sine nx in the further integration will become cos nx and divided by this n and again 0 to pi. So this will be and 1 over pi was sitting there already. So here n is square, 1 over n was there and again 1 over n will come and there is a pi outside this, outside this integral. So when we put this pi we have minus 1 power n and minus 1 over n square this pi.

(Refer Slide Time: 12:46)

$$a_n = \frac{1}{\pi} \int_0^{2\pi} f(x) \cos(nx) dx = \frac{1}{\pi} \left[ \int_0^{\pi} x \cos(nx) dx + \int_{\pi}^{2\pi} (2\pi - x) \cos(nx) dx \right]$$

$$= \frac{1}{\pi} \left[ \frac{1}{n^2} [(-1)^n - 1] - \frac{1}{n^2} [1 - (-1)^n] \right] = \frac{2}{n^2 \pi} [(-1)^n - 1]$$

$$a_n = \begin{cases} 0, & \text{when } n \text{ is even} \\ -\frac{4}{n^2 \pi}, & \text{when } n \text{ is odd} \end{cases}$$

$$\Rightarrow f(x) = \frac{\pi}{2} - \frac{4}{\pi} \left[ \cos x + \frac{\cos 3x}{3^2} + \frac{\cos 5x}{5^2} + \dots \right] \text{ where } 0 \leq x \leq 2\pi.$$

In this case as the function is continuous and  $f'$  is piecewise continuous, the series converges uniformly to  $f(x)$  and we can write the equality above.

IIT Kharagpur  
 NPTEL

So which is exactly written here. And then similarly we can integrate the second integral which is  $2\pi$  minus  $x \cos nx$  dx. And then we can further simplify this by taking this one over  $n$  square common and this minus will be adjusted here inside. So there would be just 2 times of the term. So  $2$  over  $n$  square  $\pi$  and minus  $1$  power  $n$  minus  $1$ .

So in this case what we have the an when  $n$  is an even number here. So for instance  $2, 4$  et cetera. So this will become zero and when it is odd so then these two will be added minus  $1$  minus  $1$ , so we will get minus  $2$  and then  $2$  there. So minus  $4$  over  $n$  square  $\pi$ . So having these ans, now we can just substitute in the Fourier Series, this was a naught by  $2$ . And then the rest is coming  $4$  by  $\pi$  and then we have this  $n$  square term. So  $1$  over  $1$  square,  $3$  square,  $5$  square and so on.

And in this region  $0$  to  $2\pi$ . So this, the result is having only cosine term because the function was an even function around this middle point  $\pi$  of the interval  $0$  to  $2\pi$ . So in this case one should also note that here I have used this equality sign, why equality sign is correct here. In this case the function is continuous. So if you take a look at the function so this is, this is a continuous function in the whole range this  $0$  to  $2\pi$ . This is a continuous function.

And there is  $f$  derivative, we can compute the derivative and we will notice there is also a piecewise continuous function. So we have learnt already the convergence of the Fourier Series

and we know that the Fourier Series converges uniformly indeed. The uniform convergence was the strongest convergence, which we have discussed in the lecture.

So we can write this equality there. That means for any value of  $x$  in this range the series will converge to the function  $fx$ , only the end point. But again if we look at the extension of this function as periodic extension, so the function becomes continuous also at the end point. So there is no problem to use this equality for all values of  $x$  including the end points.

(Refer Slide Time: 15:36)

**Example:** Determine the Fourier Series of  $f(x) = x^2$  on  $[-\pi, \pi]$  and hence find the value of the infinite series

$$\sum_{n=1}^{\infty} (-1)^{n+1} \frac{1}{n^2} \text{ and } \sum_{n=1}^{\infty} \frac{1}{n^2}.$$

**Solution:** The function  $f(x) = x^2$  is even on the interval  $[-\pi, \pi]$  and therefore  $b_n = 0$  for all  $n$ .

The coefficient  $a_0$  is given as

$$a_0 = \frac{1}{\pi} \int_{-\pi}^{\pi} x^2 dx = \frac{x^3}{3\pi} \Big|_{-\pi}^{\pi} = \frac{2\pi^2}{3}$$

The slide also features the NPTEL logo and the name of the lecturer, Dr. Khavari, in the bottom left corner.

And now we will consider another example where we are want to determine the Fourier Series of the function  $fx$  is equal to  $x$  square in the interval minus  $\pi$  to  $\pi$  and then we can use the convergence result to show the this infinite sums, the value of this infinite sums. So here what we have? We have the  $x$  square. So the function  $x$  square in the range minus  $\pi$  to  $\pi$ . So we have minus  $\pi$  to  $\pi$  and we know that this  $x$  square function is, is an even function in this range minus  $\pi$  to  $\pi$ . So again, we will get the cosine series and this therefore the  $b_n$ s will be against zero because of this even function.

So well this is an even function in this interval. Therefore this  $b_n$ s will be zero for all  $n$ . And then we can compute  $a_n$ s. So first the  $a_0$  is 1 over  $\pi$  and then minus  $\pi$  to  $\pi$ , so this is minus  $\pi$  here, minus  $\pi$  to  $\pi$   $x$  square  $dx$ . And then we integrate here, we

have  $x^3$  by 3 and then minus pi to pi. So we can substitute it will be just added. So  $2\pi^2$  by 3 we will get the result of this a naught.

(Refer Slide Time: 17:13)

$$\begin{aligned}
 a_n &= \frac{1}{\pi} \int_{-\pi}^{\pi} x^2 \cos(nx) dx = \frac{2}{\pi} \int_0^{\pi} x^2 \cos(nx) dx \\
 &= \frac{2}{\pi} \left[ x^2 \frac{\sin(nx)}{n} \Big|_0^{\pi} - \frac{1}{n} \int_0^{\pi} 2x \sin(nx) dx \right] \\
 &= \frac{4}{n\pi} \left[ x \frac{\cos(nx)}{n} \Big|_0^{\pi} - \int_0^{\pi} \frac{\cos(nx)}{n} dx \right] \\
 &= \frac{4}{n\pi} \left[ \frac{\pi(-1)^n}{n} - 0 \right] \\
 &= \frac{4(-1)^n}{n^2}
 \end{aligned}$$

And then we can get  $a_1$  as an as well in general. So  $1/\pi$ , minus pi to pi the function  $f(x) = x^2 \cos nx$ . So this also we can, because this  $\cos$  is an even function,  $x^2$  is even function. So we can use this  $2/\pi$  and can integrate in the region 0 to pi. So this integration, again, we come do with the partial frac, with the idea of this product rule.

So here we have  $x^2$ , we have  $x^2$  and then this  $\cos nx$  will be integrated to  $\sin nx$  over  $n$ . Then we have minus, this one over  $n$  again because this  $\cos nx$  will be  $\sin nx$  over  $n$ . So  $1/n$ . And then 0 to pi and we have the function value, the integral, differentiation of this  $x^2$ , which is  $2x$  here. And then further because this will become zero when we put pi or we put zero. So this is going to be zero in either case.

And then we have the second integral, which has to be integrated again. So here the  $x$  and the sine will be  $\cos$ . And then, again, we have the  $\cos$  there  $x$  will become 1. And then, further we can integrate the sine here, which will become anyway 0 at 0 and pi. So only because of this term we will get the value. So when  $x$  is pi, so pi and  $\cos pi$ ,  $\cos n pi$  will be minus 1 power  $n$  and divided by  $n$ . And there is a factor 4 over and pi sitting outside.

So what we have, we have 4 this pi gets cancel. So 4 minus 1n square and then minus 1 power n. And then we have this n square there. So we have 4 times minus 1 power n, n square. The value of the Fourier coefficients an and all bns are 0.

(Refer Slide Time: 19:15)

$$x^2 = \frac{\pi^2}{3} + \sum_{n=1}^{\infty} \frac{4(-1)^n}{n^2} \cos(nx) \text{ for } x \in [-\pi, \pi]$$

If we substitute  $x = 0$  in the equation, we get

$$0 = \frac{\pi^2}{3} + \sum_{n=1}^{\infty} \frac{4(-1)^n}{n^2} \Rightarrow \sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n^2} = \frac{\pi^2}{12}$$

If we now substitute  $x = \pi$  in the equation, we get

$$\pi^2 = \frac{\pi^2}{3} + \sum_{n=1}^{\infty} \frac{4(-1)^{2n}}{n^2} \Rightarrow \frac{1}{4} \frac{2\pi^2}{3} = \sum_{n=1}^{\infty} \frac{1}{n^2} \Rightarrow \sum_{n=1}^{\infty} \frac{1}{n^2} = \frac{\pi^2}{6}$$

So then we can substitute in the Fourier Series the a naught and ans the bns are 0. So we will get this cosine series because the series will not contain the sine term. And again, we can put this equality, because this series will also converge in the infactible converge absolutely and uniformly because we have again this x square function defined here for minus pi to pi and even its extension also. So everything will become, everything will become continuous.

So even including the endpoints the function in its, in its periodic extension everywhere it is going to be continuous. So at any point in this minus pi to pi or over the whole axis, when we have this periodic extension. Not just the x square will be extended to, over the whole real axis. But in this minus pi to pi and then we have to extend this, we should think this as a function and its period, in its Fourier Series is given here that Fourier Series will converge for any point x in R.

So here we have x from minus pi to pi. This will converge to the given function x square in that region, including the boundary points. So now if we substitute x equal to zero for instance in this series, so cos 0 will become one and we have the desired series or the sum of the desired series.

So we have  $0$  there and  $\pi^2$  by  $3$  and  $4$  minus  $1$  power  $n$ , which can be written in this form. So we have  $-1$  power  $n$  plus  $1$ ,  $n$  square the value is  $\pi^2$  by  $12$ .

So if we substitute now  $x$  is equal to  $\pi$ , that we have to see that what is desired values our desired series and then for what values of  $x$  we can get that series. So here we will put  $x$  equal to  $\pi$ . So here we will have, then  $-1$  power this  $2n$ . So all the positive terms will come. So this is the series, which we want to evaluate here one over  $n$  square and the value is coming  $\pi^2$  by  $6$ .

So this is a nice application that we are using this convergence theorem, we can get the value of the series of various series, we will also observe in few, in next lectures again that many complicated series we can get with the help of this convergence result.

(Refer Slide Time: 22:15)

**Further Inference:** Suppose  $f$  is integrable on  $[0, L]$

**Aim:** How to write Fourier Sine / Cosine series for  $f$  on  $[0, L]$

**Extend  $f$  to an odd/even function as:**

$$h(x) = \begin{cases} f(x), & \text{for } 0 \leq x < L \\ -f(-x), & \text{for } -L \leq x < 0 \end{cases}$$

$$g(x) = \begin{cases} f(x), & \text{for } 0 \leq x < L \\ f(-x), & \text{for } -L \leq x < 0 \end{cases}$$

The slide features three graphs on a grid. The first graph shows a red curve  $f(x)$  on the interval  $[0, 1]$ . The second graph shows the odd extension  $h(x)$  on  $[-1, 1]$ , which is a red curve for  $x \in [0, 1]$  and a blue curve for  $x \in [-1, 0]$ . The third graph shows the even extension  $g(x)$  on  $[-1, 1]$ , which is a red curve for  $x \in [0, 1]$  and a blue curve for  $x \in [-1, 0]$ . Handwritten annotations include 'Sine' and 'Cosine' with arrows, and 'F.S.' circled in blue. A small video inset of the lecturer is in the bottom right.

The further inference here if we can reduce, suppose this  $f$  is integrable and then what is our aim is to write, for instance, the Fourier sine or cosine series. So here the scenario is different now. Suppose the  $f$  is given, it's a piecewise continuous or it is integrable both ways we can write down the Fourier Series. So suppose this  $f$  is integrable in this domain  $0$  to  $L$ . And then our aim is for instance to write Fourier sine or cosine series.

So the aim here is different now, we are not writing just the Fourier Series, we want to write the Fourier sine or Fourier cosine series. And in this case what we should do then, we can extend this

$f$  to an even and odd function. So the details of this will be explained in the next lecture. So just to give some overview and the relation to what we have just done odd and even function.

So we can extend  $f$  to even and odd function such as, we define a new function  $h(x)$ , where the given  $f(x)$  is already there in the interval  $0$  to  $L$ . And in the minus  $L$  to  $L$ , we have made this odd extension of the function. Or what we can do, we can introduce this new function  $g(x)$  as  $f(x)$  again, the same function the given function in  $0$  to  $L$ . The function was defined in  $0$  to  $L$ . And then in the minus  $L$  to  $L$  we have made even extension, an even extension. So that this  $g(x)$  became an even function.

So this is an even function and this is an odd function, this is an odd function. So we can do such extensions of the function the validity of overall given function is there in  $0$  to  $L$ . Here also we have in  $0$  to  $L$  the given function. So we can thus think as follows. Suppose there is a function here  $f(x)$  which is given in  $0$  to some range,  $0$  to  $1$  it is defined by this one.

And then there are two possibilities, there could be many possibilities, but here we are extending so that the function become, this  $h(x)$  becomes the odd function. So that when we write, it is a Fourier Series, so Fourier Series of  $h(x)$  will have only the sine term, because this is an odd function. So the Fourier Series of  $h(x)$  will have only the sine terms. It will have only a sine series.

And when we stand here for  $g(x)$  which is an even function and we write the Fourier Series of this function then that Fourier Series will contain only the cosine terms. So we have the expansion of  $h(x)$  in terms of sine, we have the expansion of  $g(x)$  in terms of cosine. But what is interesting that in the, in the interval  $0$  to  $L$ , where the function is given, we have the same function  $f(x)$  which in this case will be represented by the sine series, in this case it will be represented by the cosine series. And that is the interesting the so minus called half range sine or half range cosine series we will learn in the next lecture.

(Refer Slide Time: 25:57)

**Example:** Determine the Fourier Series of  $f(x) = x, -2 < x < 2$

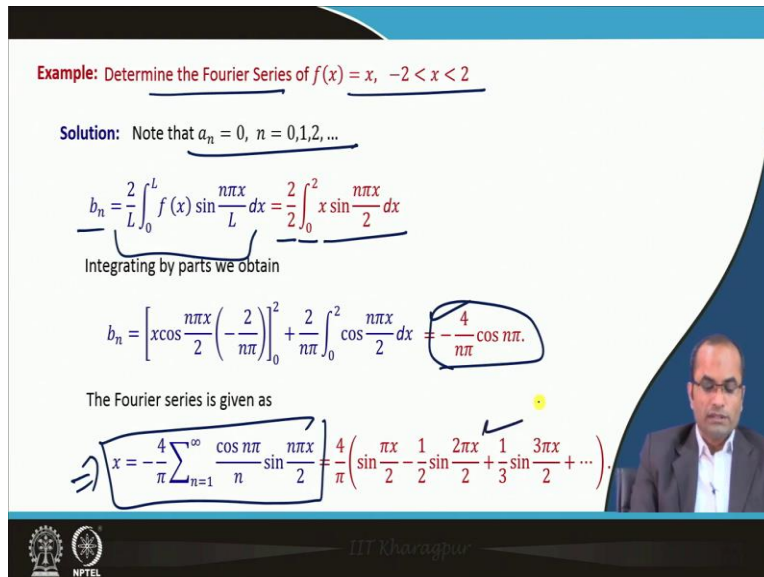

**Solution:** Note that  $a_n = 0, n = 0, 1, 2, \dots$

$$b_n = \frac{2}{L} \int_0^L f(x) \sin \frac{n\pi x}{L} dx = \frac{2}{2} \int_0^2 x \sin \frac{n\pi x}{2} dx$$

Integrating by parts we obtain

$$b_n = \left[ x \cos \frac{n\pi x}{2} \left( -\frac{2}{n\pi} \right) \right]_0^2 + \frac{2}{n\pi} \int_0^2 \cos \frac{n\pi x}{2} dx = -\frac{4}{n\pi} \cos n\pi.$$

The Fourier series is given as

$$x = -\frac{4}{\pi} \sum_{n=1}^{\infty} \frac{\cos n\pi}{n} \sin \frac{n\pi x}{2} = \frac{4}{\pi} \left( \sin \frac{\pi x}{2} - \frac{1}{2} \sin \frac{2\pi x}{2} + \frac{1}{3} \sin \frac{3\pi x}{2} + \dots \right).$$

Just the last example again. So in this lecture I have taken this  $f(x)$  is equal to  $x$ , defined in the region minus 2 to 2. And the same example I will consider in the next problem, where the interval will be taken as 0 to 2. So when we take this interval 0 to 2 in the next lecture, our aim will be to write down its sine series or cosine series by extending the function from minus 2 to 0.

So if we make that extension from minus 2 to, minus 2 to 0 as an even extension, then we will have cosine series. And if we extend that function from minus 2 to 0 as an odd function then we will have only sine series. So that precisely we will be talking about in the next lecture. But what is now here the function is defined minus 2 to 2 and we want to write Fourier Series.

So here we are not aiming for a particular series like sine or cosine. Here we want to write sine series. But naturally if we look at this function from minus 2 to 2, this is an odd function. So this is an odd function, then naturally the Fourier Series will have only the sine terms. So without any further extension or anything if we write down its Fourier Series, it will have only the sine series.

But in the next lecture we will see that if the same function  $f(x)$  is equal to  $x$  is given only in the region 0 to 2. And then we want to have its expansion as a sine series or cosine series, then accordingly we have to expand it, we have to extend it in a odd function, as a odd function or as an even function. So that we will discuss anyway in the next lecture.

So here the aim is to determine the Fourier Series, for example, for this function. And as we have seen this is an odd function so all  $a_n$ 's will become 0. For  $b_n$  we have to use this formula  $\frac{2}{L} \int_0^L f(x) \sin \frac{n\pi x}{L} dx$  and  $L$  is 2 here. So we have to  $\frac{2}{2} \int_0^2 x \sin \frac{n\pi x}{2} dx$  and this  $\int x \sin \frac{n\pi x}{L} dx$  integrating this by parts we can obtain, we can simplify this  $b_n$  to  $\frac{4}{n\pi} \cos n\pi$  and the  $\cos n\pi$ , which is  $(-1)^n$ .

So the Fourier Series now, if we write down the Fourier Series of  $f(x)$  this will have only the sine term. And this is exactly what we should be clear about it, that in this case we have written the Fourier Series of this  $f(x)$  is equal to  $x$  function. And the function was an odd function in the given interval.

The topic of the next lecture is the defining the half range sine and cosine series. So there we have the objective that the given function we want to express in terms of the sine function or in terms of the cosine functions. In this lecture we are just talking about the Fourier Series. However, if the function is an odd function, automatically we are getting the sine series, if the function is an even function automatically we are getting as cosine series.

But in the next lecture we will aim for either for cosine series or for sine series by extending the function as even or odd function. So this is the sine series and we have these references here used for preparing this lecture.

So just to conclude again that if  $f$  is an even function, we have rather simplified version of the Fourier Series where  $a_n$  can be computed by this formula  $\frac{2}{L} \int_0^L f(x) \cos \frac{n\pi x}{L} dx$ . And if  $f$  is an odd function we will get only the  $b_n$ 's, so this is odd function here. So even function will get cosine series and for odd function we will get the sine series where the  $b_n$  can be evaluated by this function.

In the next lecture what we will see now again how to write Fourier sine or cosine series for  $f$ . So there we will aim for a particular series. We will not just write the Fourier Series of a given function that we have already done in the lecture, for instance. And what we have observed that if the function is an even or an odd function the Fourier Series takes rather simple form. So that is all for this lecture and I thank you for your attention.
