Lecture -55
Properties of Laplace Transform (Contd.)

So welcome back. This is lecture number 55 on Properties of Laplace Transform and in continuation to the earlier lecture we will be discussing some more properties of the Laplace Transform.

(Refer Slide Time: 00:25)

Mainly we will discuss this division by t that if Laplace Transform what t is given that what will be the Laplace Transform of ft by t and then the Laplace Transform of Derivative that is one of the important result in this chapter, in this lecture and then also the Laplace Transform of integral will be discussed.

(Refer Slide Time: 00:53)

RECALL:

- **Shifting Properties** $L[e^{at}f(t)] = F(s-a)$
 $L[f(t-a)H(t-a)] = e^{-as}F(s)$
- **Change of Scale Properties** $L[f(at)] = \frac{1}{a}F\left(\frac{s}{a}\right)$
- **Multiplication Property** $L[t^n f(t)] = (-1)^n \frac{d^n}{ds^n} F(s)$

So coming to just to recall what we have covered, what properties we have covered in the previous lecture. So there were basically shifting properties so e power minus a if multiplied by ft then we have F s minus a there is a shift there, and if there is a shift in the function, then e power minus as comes in this transform Laplace Transform. Change of scale property so if Laplace of ft is Fs then f at is 1 over a Fs over a. And then we have also discussed this multiplication property that t power n ft is minus 1 power n and this nth derivative of this Fs.

(Refer Slide Time: 01:38)

Division by t If f is piecewise continuous on $[0, \infty)$ and is of exponential order α such that $\lim_{t \rightarrow 0^+} \frac{f(t)}{t}$ exists

then $L\left[\frac{f(t)}{t}\right] = \int_s^\infty F(u) du, \quad [s > \alpha]$

Let $g(t) = \frac{f(t)}{t} \Rightarrow f(t) = t g(t) \Rightarrow F(s) = L[f(t)] = L[tg(t)] = -\frac{d}{ds} L[g(t)]$

Integrating with respect to s , we get

$$-L[g(t)] \Big|_s^\infty = \int_s^\infty F(u) du$$

g(t) as P.C.

Division by t If f is piecewise continuous on $[0, \infty)$ and is of exponential order α such that $\lim_{t \rightarrow 0^+} \frac{f(t)}{t}$ exists

then $L\left[\frac{f(t)}{t}\right] = \int_s^\infty F(u) du, \quad [s > \alpha]$

Let $g(t) = \frac{f(t)}{t} \Rightarrow f(t) = t g(t) \Rightarrow F(s) = L[f(t)] = L[tg(t)] = -\frac{d}{ds} L[g(t)]$

Integrating with respect to s , we get

$$-L[g(t)] \Big|_s^\infty = \int_s^\infty F(s) ds$$

IIT Kharagpur

NPTEL

Division by t If f is piecewise continuous on $[0, \infty)$ and is of exponential order α such that $\lim_{t \rightarrow 0^+} \frac{f(t)}{t}$ exists

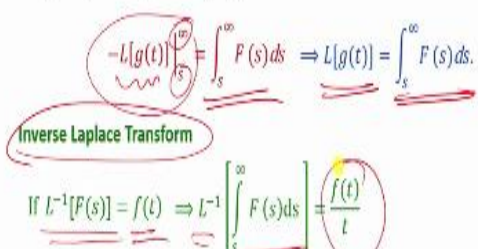

then $L\left[\frac{f(t)}{t}\right] = \int_s^\infty F(u) du, \quad [s > \alpha]$

Let $g(t) = \frac{f(t)}{t} \Rightarrow f(t) = t g(t) \Rightarrow F(s) = L[f(t)] = L[tg(t)] = -\frac{d}{ds} L[g(t)]$

Integrating with respect to s , we get

$$-L[g(t)] \Big|_s^\infty = \int_s^\infty F(s) ds \Rightarrow L[g(t)] = \int_s^\infty F(s) ds.$$

Inverse Laplace Transform

$$\text{If } L^{-1}[F(s)] = f(t) \Rightarrow L^{-1}\left[\int_s^\infty F(s) ds\right] = \frac{f(t)}{t}$$

So now we will continue with the division property so what will happen if $f(t)$ is given then $f(t)$ by t . So here we assume that the f is piecewise continuous function and is of exponential order α and we have to have this additional condition which is very important to say that $f(t)$ over t as t approaches to this from right hand side to 0 this should exist then only we can talk about the Laplace Transform of $f(t)$ over t .

And the result will be s to infinity $F(u) du$ that means when we divide by this t we have to basically integrate this Laplace Transform of f and this result is valid for all s greater than α , α was the exponential order of f there. Just looking at a proof so we take here $g(t)$ as $f(t)$ over t whose Laplace Transform we are going to compute now. So from here we have this relation that $f(t)$ is equal to t times $g(t)$.

And then F_s which is the Laplace Transform of f_t and f_t is given as this $t \cdot g_t$. So the Laplace of $t \cdot g_t$ and we know this from the previous lecture the property that when we multiply by t it is like minus d over ds the Laplace Transform of g_t . Well if we integrate now with respect to s this relation here F_s is equal to minus d over ds Laplace of g_t then we will get so this side first. So we will get here the Laplace of g_t .

Because this was a derivative and we integrate so this derivative will be removed we have the limit s to infinity and then the right hand side this F_s will be integrated from s to infinity. Now we have to look at these limits here. So we have this Laplace Transform of g_t and we are looking at that what will happen here when this s goes to infinity. This is a function of s and we are looking at what will happen when s goes to infinity.

And remember in the result where we discuss the existence of the Laplace Transform we notice that if a given function f_t is piecewise continuous function of exponential order, then its Laplace Transform goes to 0 as s goes to infinity. So here we have this function g_t now we have to see whether g_t is piecewise continuous and it is of exponential order α . So concerning the continuity piecewise continuity of g_t , so here g_t is f_t over t .

And f is piecewise continuous so we have the piecewise continuity of t already and t is anyway continuous. So other than this because there is a point here when t approaches to 0 so other than that there is no issue about the piecewise continuity of this quotient here which is we have denoted by g_t , but the question is that when t approaches to 0 this limit may not exist that means the limit t approaches to 0 plus this f_t over t may not exist.

Because that is not coming automatically from the piecewise continuity of f . The piecewise continuity of f the piecewise continuity of f_t says that the limit f_t when t approaches to 0 that exist, but here we are dividing by t so this may not exist in general. So therefore we have to say that this limit f_t over t exist and this is exactly to make this function g_t as piecewise continuous. So the function g_t is piecewise continuous because this is a ratio of this function f_t divided by t and as t approaches to 0.

We have this additional assumption that f_t over t exist. So this is very important for the piecewise continuity of function g_t . Regarding the exponential order since f is of exponential order and here we are talking about this division by t and normally we look at this limit t approaches to infinity. So if this f_t has this boundedness by the exponential function definitely here we are dividing even by t .

So this $f(t)$ over t will definitely have the boundedness for large values of t . So the exponential order α is not distributed by dividing t and this piecewise continuity is maintained because we have this additional assumption that $f(t)$ over t limit t approaches to 0 plus exist. So having this $g(t)$ piecewise continuous function of exponential order this its Laplace Transform will go to 0 as s approaches to infinity.

So the first limit here will be 0 and then when we substitute this s so we have simply the Laplace of $g(t)$ and the right hand side we have s to infinity $F(s) ds$ and this is the result we want to prove. For its counterpart the Inverse Laplace Transform so we say that if $L^{-1} F(s)$ is $f(t)$ then the L^{-1} of this integral s to infinity $F(s) ds$ will be $f(t)$ divided by t .

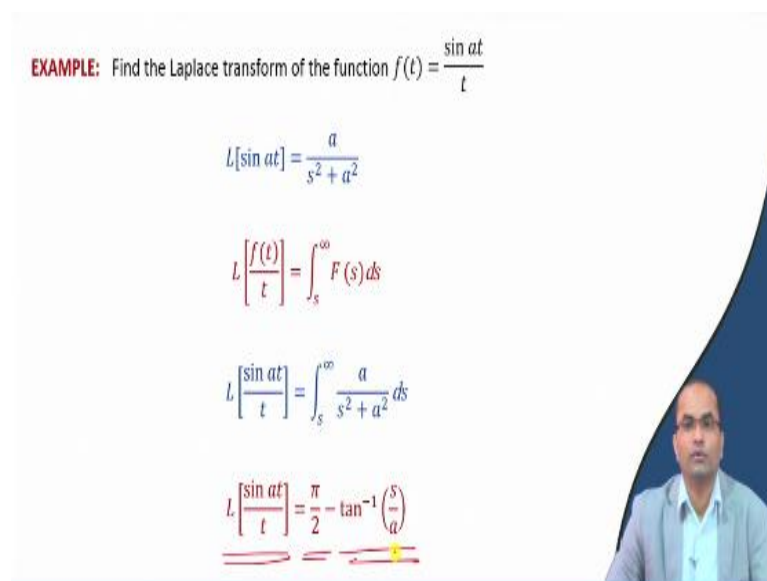

(Refer Slide Time: 07:12)

EXAMPLE: Find the Laplace transform of the function $f(t) = \frac{\sin at}{t}$

$$L[\sin at] = \frac{a}{s^2 + a^2}$$

$$L\left[\frac{f(t)}{t}\right] = \int_s^\infty F(s) ds$$

$$L\left[\frac{\sin at}{t}\right] = \int_s^\infty \frac{a}{s^2 + a^2} ds$$

$$L\left[\frac{\sin at}{t}\right] = \frac{\pi}{2} - \tan^{-1}\left(\frac{s}{a}\right)$$

So we will discuss are some examples now. So we want to find for instance the Laplace Transform of this function $f(t)$ as $\sin at$ over t . So the Laplace of $\sin at$ we know a over s square plus a square and then we can apply this property of the Laplace Transform that means we have to just integrate this Laplace of $\sin at$ that is integral s to infinity a over s square plus a square ds and that means this Laplace of this $\sin at$ over t is π by 2 minus this \tan inverse s over a .

(Refer Slide Time: 07:51)

EXAMPLE: Find the Laplace transform of the function

$$f(t) = \frac{2 \sin t \sinh t}{t}$$

$$L\left[\frac{f(t)}{t}\right] = \int_s^\infty F(u) du$$

$$\tan^{-1} x - \tan^{-1} y = \tan^{-1} \frac{x-y}{1+xy}$$

$$L[f(t)] = \int_s^\infty L[\sin t (e^t - e^{-t})] ds$$

$$L[\sin t (e^t - e^{-t})] = L[e^t \sin t] - L[e^{-t} \sin t] = \frac{1}{1+(s-1)^2} - \frac{1}{1+(s+1)^2}$$

$$L[f(t)] = \int_s^\infty \left[\frac{1}{1+(s-1)^2} - \frac{1}{1+(s+1)^2} \right] ds = \tan^{-1}(s-1) \Big|_s^\infty - \tan^{-1}(s+1) \Big|_s^\infty$$

$$= \frac{\pi}{2} - \tan^{-1}(s-1) - \frac{\pi}{2} + \tan^{-1}(s+1) = \tan^{-1} \left(\frac{2}{s^2} \right)$$

The next example we want to find the Laplace Transform of this function again the similar situation it is being divided by t here. So if we find the Laplace Transform of 2 sin t sin hyperbolic t and then we can apply this property division by t and we can get this Laplace Transform of this given function. So Laplace Transform of this ft by t is s to infinity Fu du. So we have the Laplace Transform of ft Laplace of sin t e power t minus e power minus t ds.

And the Laplace of this sin t e power t minus e power minus t that we can compute as Laplace e power t sin t and minus Laplace of e power minus t sin t. So here both the places we can use these properties. So we have here 1 over 1 plus s square s minus 1 square and then minus 1 over 1 plus s square plus 2 and here we have the Laplace of this ft then which is given already there.

So Laplace of ft will be integral s to infinity the Laplace of sin t and e power t minus this t and this has to be integrated over s which is given here now. So by the direct integration we have this tan inverse s minus 1 and then the limit s to infinity minus this tan inverse s plus 1 the limits again this s to infinity and then we have here pi by 2 and minus this tan inverse s minus 1.

Because when s approaches to infinity this tan inverse infinity will be pi by 2 and we have this tan inverse s minus 1 and then minus again in the same situation (())(09:50) tan inverse this infinity will be pi by 2 and then tan inverse s plus 1. So this pi by 2 and pi by 2 will

cancel out and then using this property that tan inverse x minus tan inverse y is equal to tan inverse x minus y over 1 plus xy. We can further simplify to get tan inverse 2 over s square.

(Refer Slide Time: 10:12)

EXAMPLE: Find the inverse Laplace transform of the function $\int_s^{\infty} \frac{1}{s(s+1)} ds$

$$L^{-1} \left[\frac{1}{s(s+1)} \right] = L^{-1} \left[\frac{1}{s} - \frac{1}{s+1} \right]$$

$$= L^{-1} \left[\frac{1}{s} \right] - L^{-1} \left[\frac{1}{s+1} \right]$$

$$= 1 - e^{-t}$$

$$L^{-1} \left[\int_s^{\infty} \frac{1}{s(s+1)} ds \right] = \frac{1 - e^{-t}}{t}$$

$L^{-1} \left[\int_s^{\infty} F(s) ds \right] = \frac{f(t)}{t}$

So now the next example we have to find the inverse Laplace Transform of this function s to infinity 1 over s s plus 1 ds that means this L inverse of this integral we know this property so we need this ft over t. So what is ft now that is the Laplace inverse of this integrant 1 over s plus 1. So we have to find the Laplace inverse of 1 over s s plus 1 which can be done using this partial fractions.

So we have 1 over s minus 1 over s and then the Laplace inverse using the linearity property we have here L inverse 1 over s L inverse 1 over s plus 1 which is 1 here and then 1 over s plus 1 is 1 e power minus t. So we have the Laplace inverse of this integrant and then this property says that L inverse for this integral will be just ft divided by t. So the L inverse of this s to infinity 1 over s s plus 1 ds that will be 1 minus e power minus t divided by t.

(Refer Slide Time: 11:27)

Laplace Transform of Derivatives Derivative Theorem

Suppose f is continuous on $[0, \infty)$ and is of exponential order α and that f' is piecewise continuous on $[0, \infty)$. Then

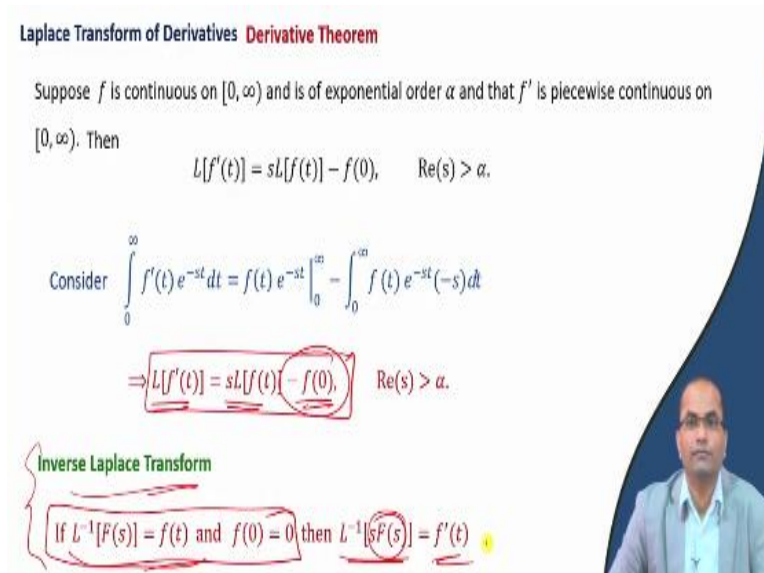

$$L[f'(t)] = sL[f(t)] - f(0), \quad \text{Re}(s) > \alpha.$$

Consider $\int_0^{\infty} f'(t) e^{-st} dt = f(t) e^{-st} \Big|_0^{\infty} - \int_0^{\infty} f(t) e^{-st} (-s) dt$

$$\Rightarrow L[f'(t)] = sL[f(t)] - f(0), \quad \text{Re}(s) > \alpha.$$

Inverse Laplace Transform

If $L^{-1}[F(s)] = f(t)$ and $f(0) = 0$ then $L^{-1}[sF(s)] = f'(t)$

Coming to the Laplace Transform of derivatives so we have this the so called derivative theorem and indeed this is one of the results in this transform calculus because it has several applications for solving integral equations differential equations including ordinary and partial differential equations. So suppose this f is continuous and is of exponential order α and f' is piecewise continuous.

So under these conditions we have this nice result that the Laplace Transform of $f'(t)$ is s times Laplace of $f(t)$ minus $f(0)$ and this is valid for real s greater than α and this property again says similar to what we had in Fourier Transform that the Laplace Transform of the derivative is equal to s the Laplace Transform of $f(t)$ and minus this $f(0)$. So we consider this integral 0 to infinity $f'(t) e^{-st} dt$.

And then apply this idea of the integration by parts that means we have $f(t)$ there e^{-st} and this limit and then again here this $f(t)$ will be there and this minus (12:44) minus st . So here now we have to put the limit as this t approaches to infinity and this t approaches to 0 . So when t approaches to infinity this e^{-st} will make this term 0 and then when t approaches to 0 we will get this $f(0)$.

So we have this with minus $f(0)$ and at this place this s and minus s minus sign and this minus s will make it plus s and then the result is Laplace Transform of $f(t)$. So we have this result that the Laplace Transform of $f'(t)$ is equal to s Laplace of $f(t)$ minus $f(0)$. Its counterpart for the

Inverse Laplace Transform we usually use this result in a slightly different form that if we know that the L inverse of $F(s)$ is $f(t)$.

And in addition to this we also require that $f(0)$ is 0 so if there is no this term here we can just invert it. So we have this L inverse of this $sF(s)$ is equal to the derivative of f with respect to t . So we will apply to one problem this Inverse Laplace Transform property.

(Refer Slide Time: 14:04)

Derivative Theorem $L[f'(t)] = sL[f(t)] - f(0)$

Remark 1:
Suppose $f(t)$ is not continuous at $t = 0$, then the results of the above theorem takes the following form
$$L[f'(t)] = sL[f(t)] - f(0+0)$$

Remark 2:
An interesting feature of the derivative theorem is that $L[f'(t)]$ exists without the requirement of f' to be of exponential order.

Recall the existence of Laplace transform of $f(t) = 2te^{t^2} \cos(e^{t^2})$
which is obvious now by the derivative theorem because $f(t) = [\sin(e^{t^2})]'$

Handwritten annotations:
- A red circle around $f(t) = 2te^{t^2} \cos(e^{t^2})$ with an arrow pointing to $\frac{d}{dt}(\sin(e^{t^2}))$.
- A red circle around $\frac{d}{dt}(\sin(e^{t^2}))$ with an arrow pointing to $L\{\sin(e^{t^2})\}$.
- A red circle around $L\{\sin(e^{t^2})\}$ with an arrow pointing to $f(0)$ in the theorem formula.

This derivative theorem we have some remarks now that if $f(t)$ is not continuous at t equal to 0 for instance because this continuity we assume then we have taken here $f(0)$. Otherwise this can be replaced by this limit $f(0+)$ plus that means the limit of this function f as t approaches to 0 from the right hand side and here we have this s Laplace of $f(t)$ here we have the Laplace of f' .

So this is slightly more general than the earlier result. So coming to the remark 2 an interesting feature of this derivative theorem is that this Laplace of f' exists without the requirement of f' to be exponential order. We have in the theorem not assumed that f' to be of exponential order, but we got the Laplace Transform of f' and just to recall the existence of this Laplace Transform we have discuss in one of the lectures that the Laplace Transform of this function exist.

Whereas this function is not of exponential order and now it is clear which is obvious from this derivative theorem because this given function is the derivative of this $\sin(e^{t^2})$ and then if we apply the derivative theorem which says that the Laplace of this would

be now s times the Laplace of ft so Laplace of sin e power t square and minus f0 which is sin 1.

So this existence of the Laplace of this function now it is clear from here which says that it is s times the Laplace of this function which is continuous function of exponential order. So the Laplace exist here and then minus sin 1. So that is obvious now from this derivative theorem the existence of for instance the Laplace of this function.

(Refer Slide Time: 16:12)

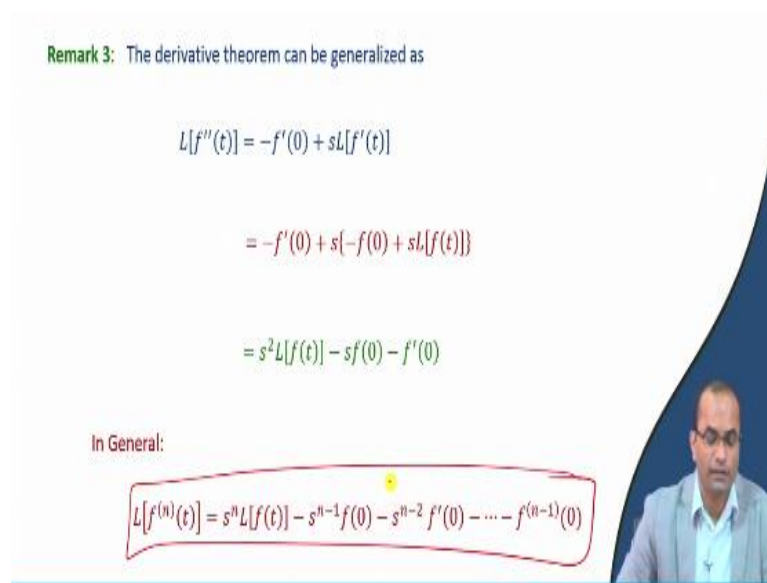

Remark 3: The derivative theorem can be generalized as

$$L[f''(t)] = -f'(0) + sL[f'(t)]$$

$$= -f'(0) + s[-f(0) + sL[f(t)]]$$

$$= s^2L[f(t)] - sf(0) - f'(0)$$

In General:

$$L[f^{(n)}(t)] = s^n L[f(t)] - s^{n-1}f(0) - s^{n-2}f'(0) - \dots - f^{(n-1)}(0)$$

This derivative theorem can be generalized that if we take the double derivative that means we have minus so this is the derivative here of ft and then we are talking about the derivative. So here our function is this f prime so the direct application of the derivative theorem says minus f prime 0 plus this s the Laplace of f prime t that means this minus f prime 0 plus this s and then here we can apply the derivative theorem again minus f0 plus s the Laplace of ft.

So we have here this s square the Laplace of ft minus this sf0 and minus s prime 0. So in general we have this result now for any derivative we can get. So Laplace of the nth order derivative of this f is equal to the s power n the Laplace of ft and then keep on reducing the power of this s.

So we have s power n minus 1 f0 s power n minus 2 f prime 0 here the derivative will keep on increasing and the power of this s will be decreasing. So in that way this is a very general result where we can deal the secondary derivative, third derivative or any order derivative of the function.

(Refer Slide Time: 17:33)

EXAMPLE: Determine $L[\sin^2 \omega t]$.

Assume: $f(t) = \sin^2 \omega t \Rightarrow f'(t) = 2 \sin \omega t \cos \omega t \omega = \omega \sin 2\omega t$

Derivative Theorem: $L[f'(t)] = sL[f(t)] - f(0)$

$L[\omega \sin 2\omega t] = sL[\sin^2 \omega t] - 0$

$L[\sin^2 \omega t] = \frac{\omega}{s} \left(\frac{2\omega}{s^2 + 4\omega^2} \right) = \frac{2\omega^2}{s(s^2 + 4\omega^2)}$

So some applications so if you want to find for example this sin square omega t and we will naturally want to use this derivative theorem. So we have let us take this ft sin square t and if we get this derivative so directly we do not know the result of this sin square t the Laplace Transform of sin square t, but if we take the derivative we are getting 2 sin omega t cos omega t and this omega factor which is omega times this sin 2 omega t.

And this sin at we know the derivative we know the Laplace Transform of sin at. So we can use now the derivative theorem which says the derivative of this omega sin 2t which is a derivative of this. So the derivative of this the Laplace Transform is s the Laplace Transform of the ft sin square t minus this f0. So f0 is sin 0 is 0.

So we have this due to the derivative theorem and then this Laplace of sin square t we can get this w this s will go to the other side. And then the Laplace of sin 2 omega t which is 2 omega over s square plus 4 omega square which we can write like 2 omega square over this s and then we have s square plus this 4 omega square.

(Refer Slide Time: 19:02)

EXAMPLE: Using derivative theorem, find $L[t^n]$

Let $f(t) = t^n$

$$f'(t) = nt^{n-1}, \quad f''(t) = n(n-1)t^{n-2}, \dots, \quad f^{(n)}(t) = n!$$

Derivative Theorem

$$L[f^{(n)}(t)] = s^n L[f(t)] - s^{n-1}f(0) - s^{n-2}f'(0) - \dots - f^{(n-1)}(0).$$

$L(1) = \frac{1}{s}$

$$L[n!] = s^n L[t^n] \Rightarrow L[t^n] = \frac{n!}{s^{n+1}}$$

Well so here we are using this derivative theorem we will also find the Laplace of t power n which we have already evaluated, but this demonstrate using this derivative theorem how easy is to get this Laplace Transform of t power n . We know that if we have this $f(t)$ is t power n then its first derivative is nt^{n-1} then $n(n-1)t^{n-2}$ and so on.

The n th derivative will have just the factorial n and if we use this derivative theorem that the Laplace of f the n th order derivative is given by this one what is interesting here that $f(0)$ is 0 the f' is also 0 at 0 this is also 0 . So all these derivatives up to $n-1$ they all will become 0 . So this portion will be 0 for this function and then we have only this Laplace t power n is equal to s power n and Laplace of $f(t)$.

So applying this the left hand side we have the Laplace of this n th derivative which is factorial n . So Laplace of factorial n is equal to s power n and then the Laplace of t power n . The Laplace of this 1 because factorial n is constant so here Laplace of 1 we know it is 1 over s . So we have 1 over s from here with factorial n and then s power n will go to the denominator there.

So we have the result that the Laplace of t power n is factorial n over s power $n+1$. So we got this result just by using that the Laplace Transform of 1 is 1 over s .

(Refer Slide Time: 20:54)

EXAMPLE: Using derivative theorem, find $L[\sin kt]$

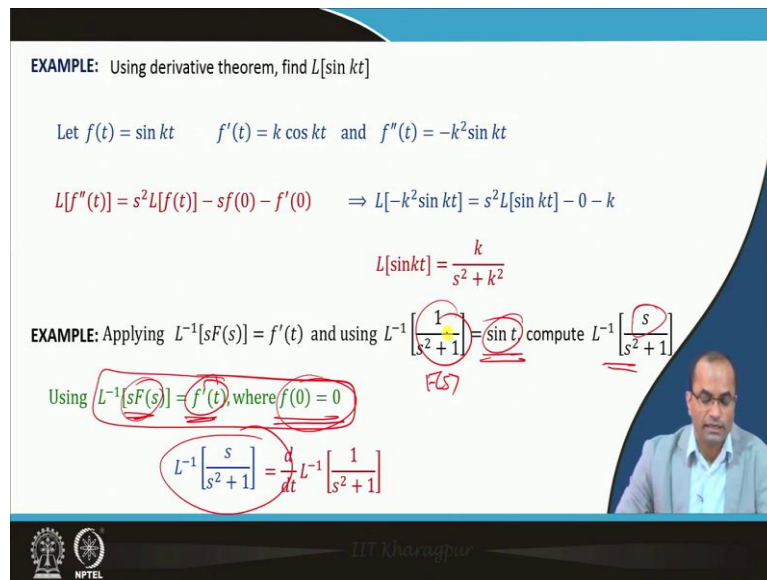

Let $f(t) = \sin kt$ $f'(t) = k \cos kt$ and $f''(t) = -k^2 \sin kt$

$$L[f''(t)] = s^2 L[f(t)] - sf(0) - f'(0) \quad \Rightarrow \quad L[-k^2 \sin kt] = s^2 L[\sin kt] - 0 - k$$

$$L[\sin kt] = \frac{k}{s^2 + k^2}$$

EXAMPLE: Applying $L^{-1}[sF(s)] = f'(t)$ and using $L^{-1}\left[\frac{1}{s^2 + 1}\right] = \sin t$, compute $L^{-1}\left[\frac{s}{s^2 + 1}\right]$

Using $L^{-1}[sF(s)] = f'(t)$, where $f(0) = 0$

$$L^{-1}\left[\frac{s}{s^2 + 1}\right] = \frac{d}{dt} L^{-1}\left[\frac{1}{s^2 + 1}\right]$$

EXAMPLE: Using derivative theorem, find $L[\sin kt]$

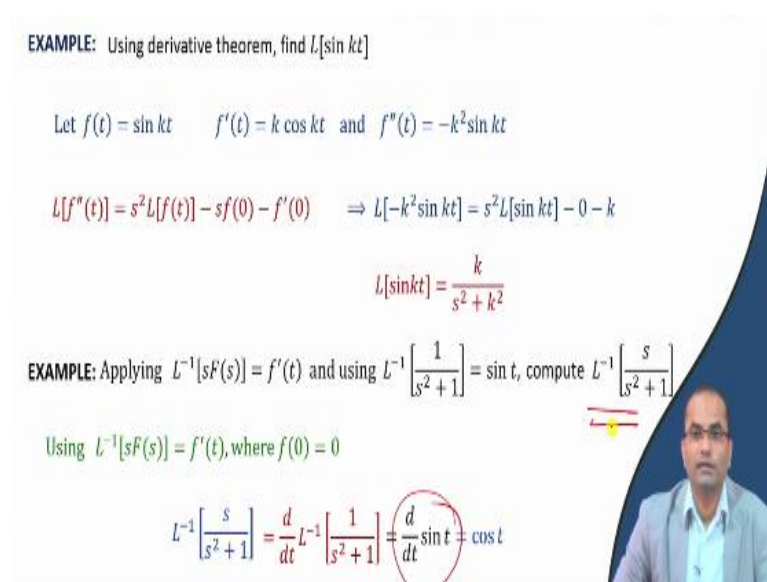

Let $f(t) = \sin kt$ $f'(t) = k \cos kt$ and $f''(t) = -k^2 \sin kt$

$$L[f''(t)] = s^2 L[f(t)] - sf(0) - f'(0) \quad \Rightarrow \quad L[-k^2 \sin kt] = s^2 L[\sin kt] - 0 - k$$

$$L[\sin kt] = \frac{k}{s^2 + k^2}$$

EXAMPLE: Applying $L^{-1}[sF(s)] = f'(t)$ and using $L^{-1}\left[\frac{1}{s^2 + 1}\right] = \sin t$, compute $L^{-1}\left[\frac{s}{s^2 + 1}\right]$

Using $L^{-1}[sF(s)] = f'(t)$, where $f(0) = 0$

$$L^{-1}\left[\frac{s}{s^2 + 1}\right] = \frac{d}{dt} L^{-1}\left[\frac{1}{s^2 + 1}\right] = \frac{d}{dt} \sin t = \cos t$$

Now using this derivative theorem we will find the Laplace Transform of $\sin kt$. So $f(t)$ is $\sin kt$ if we assume. So here purely the application of the derivative theorem will be used to find out the $\sin kt$. So the derivative of first derivative is $k \cos kt$ and we take another derivative once more we have minus k^2 and the $\sin kt$. Now we will apply this derivative theorem for the second order.

So Laplace of this $f''(t)$ is s^2 Laplace of $f(t)$ minus $sf(0)$ which is 0 and $f'(0)$ which is just k there. So substituting these values there we have the Laplace of minus $k^2 \sin kt$ is equal to s^2 and the Laplace of $\sin kt$ and minus this 0 and we have

minus f' as $f(0)$ as k . So we have this identity now which here we have Laplace kt here also we have Laplace kt so these can be merged now.

And there will be a factor $k^2 + s^2$ and the other side we have this k so k over $s^2 + k^2$ will be the value of the Laplace kt . Applying this L^{-1} $s f(s)$ as $f'(t)$ and using this result that the Laplace inverse 1 over $s^2 + 1$ is $\sin t$. We want to find for instance the Laplace inverse just if we multiply here by s so that means s over $s^2 + 1$ using naturally the idea of this derivative theorem.

So from the derivative theorem we know that $L^{-1} s F(s)$ is $f'(t)$ and this is valid when $f(0) = 0$. So in our case if we take this $f(t)$ as $\sin t$ $f(0)$ is 0 and $s F(s)$. So this is exactly $s F(s)$ if this is $F(s)$ then we have there $s F(s)$. So the Laplace Inverse of $s F(s)$ will be $f'(t)$ that means the derivative of $\sin t$. So the derivative of $\sin t$ is $\cos t$. So this L^{-1} of s over $s^2 + 1$ is nothing but $\cos t$.

(Refer Slide Time: 23:28)

Laplace Transform of Integrals

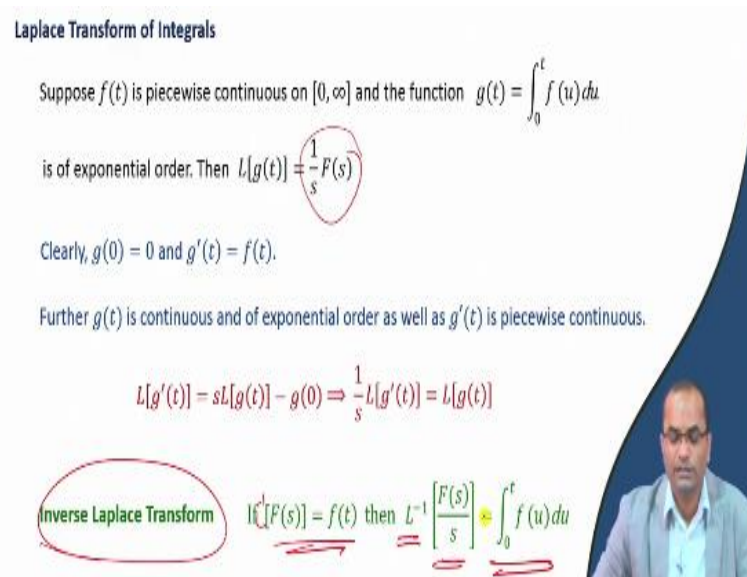

Suppose $f(t)$ is piecewise continuous on $[0, \infty)$ and the function $g(t) = \int_0^t f(u) du$ is of exponential order. Then $L[g(t)] = \frac{1}{s} F(s)$

Clearly, $g(0) = 0$ and $g'(t) = f(t)$.

Further $g(t)$ is continuous and of exponential order as well as $g'(t)$ is piecewise continuous.

$$L[g'(t)] = sL[g(t)] - g(0) \Rightarrow \frac{1}{s} L[g'(t)] = L[g(t)]$$

Inverse Laplace Transform $L^{-1}\left[\frac{F(s)}{s}\right] = f(t)$ then $L^{-1}\left[\frac{F(s)}{s}\right] = \int_0^t f(u) du$

Now finally we want to discuss this Laplace Transform for integrals and here we assume that $f(t)$ is piecewise continuous on this interval 0 to open infinity and this function $g(t)$ as 0 to infinity $\int_0^t f(u) du$. Suppose this $g(t)$ is the integral of this f from 0 to t then we assume that this function is of exponential order and then the Laplace Transform of $g(t)$ we want to find as 1 over $s F(s)$.

So clearly here $g(0)$ because when t is 0 here we will get this $g(0)$ so $g(0)$ is 0 and $g'(t)$ again from there $g'(t)$ is just $f(t)$. So now this $g(t)$ is continuous because f is piecewise continuous

function and this is integral $g(t)$ is the integral there so $g(t)$ will become continuous and is of exponential order that is given there in the problem and $g'(t)$ is piecewise continuous because $g'(t)$ is $f(t)$ and $f(t)$ is piecewise continuous.

So naturally $g'(t)$ is piecewise continuous. So this $g(t)$ is continuous of exponential order and $g'(t)$ is piecewise continuous. So we can use this derivative theorem just discussed before that Laplace of $g'(t)$ is s Laplace of $g(t)$ minus this $g(0)$. So we have 1 over s Laplace of $g'(t)$ is equal to Laplace of $g(t)$ because this $g(0)$ is 0 . So we got the result already that the Laplace of $g(t)$ is 1 over s .

And the Laplace of this $g'(t)$ which is $f(t)$ so the Laplace of $f(t)$ which is $F(s)$ there. For inverse counterpart so we have this as follows that the L inverse of this $F(s)$ is $f(t)$ in that case L inverse of this 1 over $sF(s)$ will be $g(t)$ that means 0 to t $f(u) du$.

(Refer Slide Time: 25:41)

EXAMPLE: Given that $L\left[\frac{\sin t}{t}\right] = \int_s^\infty \frac{1}{1+s^2} ds$.

Find the Laplace transform of the integral $\int_0^t \frac{\sin u}{u} du$

$L\left[\int_0^t \frac{\sin u}{u} du\right] = \frac{1}{s} L\left[\frac{\sin t}{t}\right]$

$= \frac{1}{s} \int_s^\infty \frac{1}{1+s^2} ds$

$L\left[\int_0^t \frac{\sin u}{u} du\right] = \frac{1}{s} \cot^{-1} s = \frac{\pi}{2} - \tan^{-1} s$

$L\left[\int_0^t f(u) du\right] = \left[\frac{F(s)}{s}\right]$

Coming to the examples so we discuss here that it is given that $\sin t$ over t the Laplace of this is s to infinity 1 over $1 + s^2$ ds and we want to find the Laplace Transform of this integral 0 to t and $\sin u$ over u . So if \sin over t is given then what is the Laplace of the integral of this $\sin t$ over t . We know the result that the integral of the Laplace of the integral is $F(s)$ over s .

So basically we have to get just $F(s)$ the $F(s)$ is the Laplace Transform of this integrant here that is $\sin u$ over u and that Laplace is given already in the problem. So the Laplace of this integral will be 1 over s the Laplace of $\sin t$ over t which is already there s to infinity 1 over 1

plus s square and this 1 over 1 plus s square is tan inverse s and then the limit s to infinity which is tan inverse infinity is pi by 2 minus this tan inverse s. And this pi by 2 minus tan inverse s is 1 by s cot inverse s. So this is done for the integral.

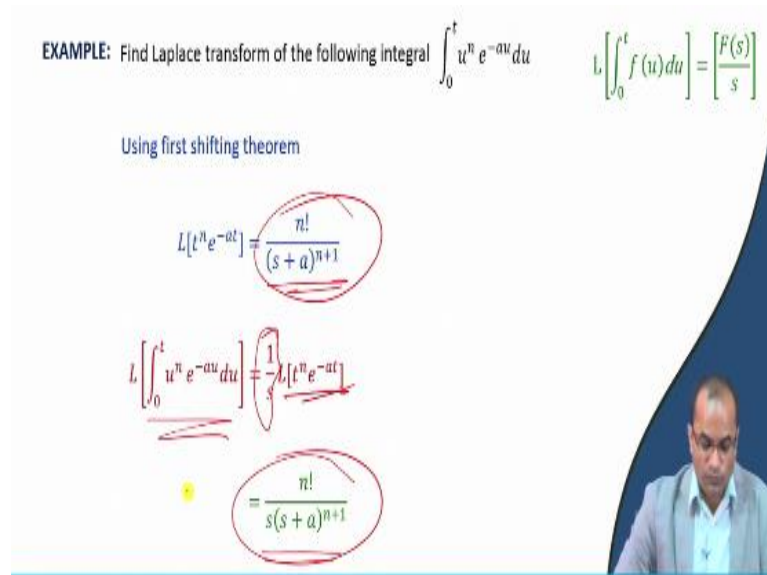

(Refer Slide Time: 27:01)

EXAMPLE: Find Laplace transform of the following integral $\int_0^t u^n e^{-au} du$ $L\left[\int_0^t f(u) du\right] = \left[\frac{F(s)}{s}\right]$

Using first shifting theorem

$$L[t^n e^{-at}] = \frac{n!}{(s+a)^{n+1}}$$

$$L\left[\int_0^t u^n e^{-au} du\right] = \frac{1}{s} L[t^n e^{-at}]$$

$$= \frac{n!}{s(s+a)^{n+1}}$$

The next is find the Laplace Transform of this integral 0 to t u power n e power minus this au. So again we will apply this that the integral here of this fu du so here fu is u power n e minus au and so we have to get just the Laplace Transform of this and then we can just divide by s. So the Laplace Transform of t power n e power minus at by this shift theorem.

We know already that is a factorial n over s plus a this plus a is coming because of this shift there. So we have factorial n s plus a power n and then this integral will be just 1 over s and this factorial n over s into this s plus 1 the power n plus 1. So that is also done.

(Refer Slide Time: 28:02)

EXAMPLE: Compute $L^{-1}\left[\frac{1}{s(s^2+1)}\right]$

$$L^{-1}\left[\frac{1}{s(s^2+1)}\right] = \int_0^t L^{-1}\left[\frac{1}{s^2+1}\right] ds = \int_0^t \sin u \, du = 1 - \cos t$$

EXAMPLE: Find inverse Laplace transform of $\frac{s-1}{s^2(s^2+1)}$

$$L^{-1}\left[\frac{s-1}{s^2(s^2+1)}\right] = L^{-1}\left[\frac{s}{s^2(s^2+1)}\right] - L^{-1}\left[\frac{1}{s^2(s^2+1)}\right] = \cos t - \sin t$$

$$L^{-1}\left[\frac{s-1}{s^2(s^2+1)}\right] = \int_0^t (\cos u - \sin u) \, du = \sin t + \cos t - 1$$

$$L^{-1}\left[\frac{s-1}{s^2(s^2+1)}\right] = \int_0^t (\sin u + \cos u - 1) \, du = 1 - t + \sin t - \cos t$$

And now we want to compute for instance this L inverse 1 over s s square plus 1 and we will use this analogous definition of this integral for the inverse. So we have L inverse Fs over s so if we know for instance the L inverse of 1 over s square plus 1 then we can get for Fs when we divide by s just by integrating that function. So here we need to get this L inverse of 1 over s square plus 1 which we know it is a sin function.

So we have sin u then du which we have to integrate now here that will give 1 minus cos t because we have integrated here 0 to t. The last example we want to find the sin inverse find this Inverse Laplace Transform of s minus 1 over s square into this s square plus 1. So here we have this s there which can be handled with this division theorem. So we need to find L inverse of s minus 1 over s square plus 1 which again the linearity says that this is L inverse of s over s square plus 1 minus L inverse 1 over s square plus 1.

And then here we have cos t and then this is sin t so if we just consider this 1 over s there that means we have to integrate this 0 to t that means 0 to t this cos u minus sin u over this du. So here we have the cos will be sin this t and sin will be cos u. So we have the cos t and then cos 0, 1 will be also coming there. So we have now this here the L inverse of this s minus 1 over s square plus 1.

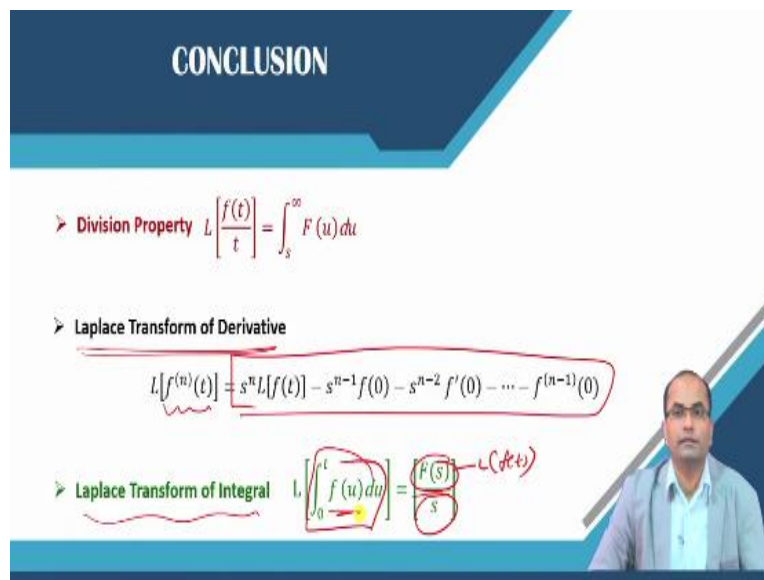

But in the question it is asked for this s square. So we have to apply this once again to have to accommodate this one more s there that means we have to integrate this sin t plus cos t minus 1 from 0 to t over this du. So after this integration we get 1 minus t plus sin t minus this cos t.

(Refer Slide Time: 30:21)

Well, so these are the references we have used for preparing this lecture.

(Refer Slide Time: 30:26)

And just to conclude so today we have discuss this division property which says that if the Laplace Transform of this $f(t)$ is $F(s)$ then we can get this Laplace of $f(t)/t$ as $\int_s^\infty F(u) du$. So we have to integrate there if you want to accommodate this extra t in this denominator there. The Laplace of the derivative one of the important most important result in this Laplace Transform.

So we have the Laplace of this $f(t)$ the n th derivative can be computed with this help of this formula and this Laplace of the integral that means if we have this $f(t)$ and we want to get the

Laplace of this integral then this is just the $F(s)$ which is the Laplace Transform of that $f(t)$ and we have to divide here by s to accommodate this integral there.

So with the help of all these properties we have observed that the evaluation of Laplace as well as the Inverse Laplace Transform of much more complex functions become easier. So we will continue with some more properties in the last lecture and that is all for this lecture and I thank you for your attention.
