

**An Introduction to Riemann Surfaces and Algebraic Curves: Complex 1  
-dimensional Tori and Elliptic Curves**  
**Dr. Thiruvallloor Eesanaipaadi Venkata Balaji**  
**Department of Mathematics**  
**Indian Institute of Technology, Madras**

**Lecture - 24**  
**Orbits of the Integral Unimodular Group in the Upper Half-Plane**

(Refer Slide Time: 00:09)

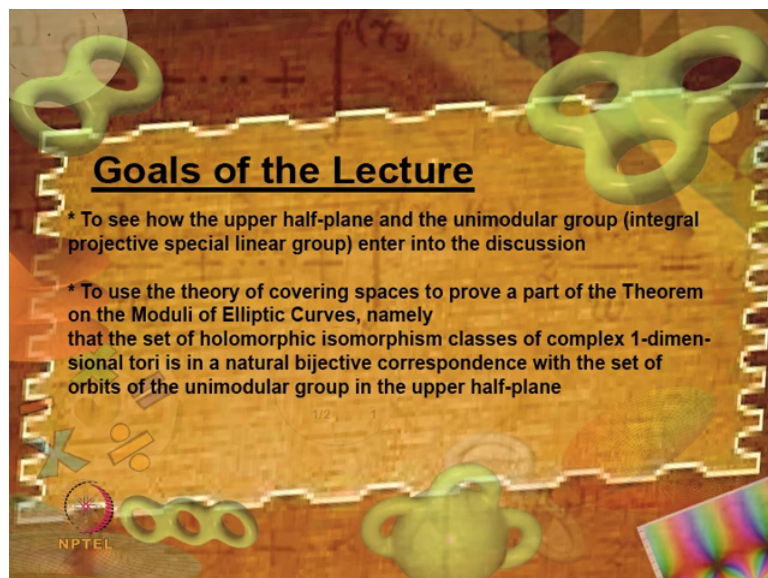

**Goals of the Lecture**

- \* To ask for a description of the set of holomorphic isomorphism classes of complex tori
- \* To state the Theorem on the Moduli of Elliptic Curves that not only answers the question above but also shows that the set above has a beautiful God-given geometry

The slide features a decorative border with mathematical symbols like  $\pi$ ,  $\infty$ ,  $\frac{1}{2}$ , and  $1$ . It also includes 3D models of tori and a colorful fractal-like pattern in the bottom right corner. The NPTEL logo is visible in the bottom left.

(Refer Slide Time: 00:15)

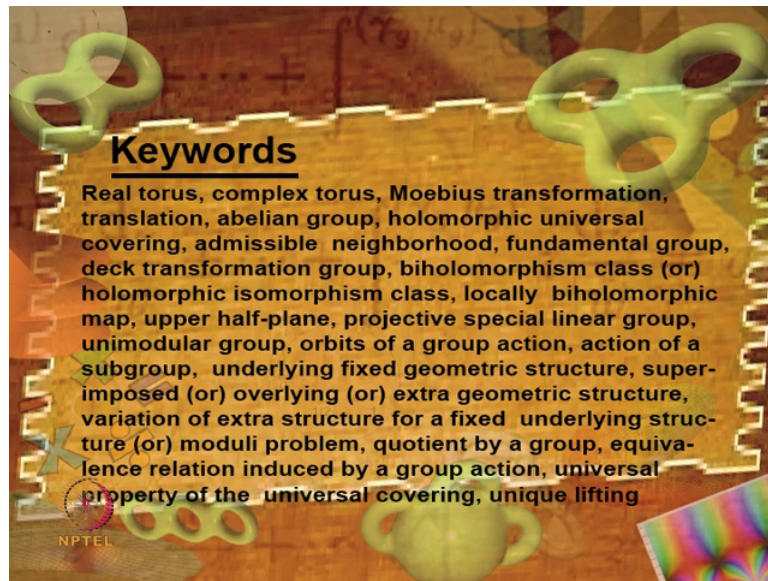

**Goals of the Lecture**

- \* To see how the upper half-plane and the unimodular group (integral projective special linear group) enter into the discussion
- \* To use the theory of covering spaces to prove a part of the Theorem on the Moduli of Elliptic Curves, namely that the set of holomorphic isomorphism classes of complex 1-dimensional tori is in a natural bijective correspondence with the set of orbits of the unimodular group in the upper half-plane

This slide is identical in layout to the previous one, featuring the same decorative border, mathematical symbols, 3D torus models, and fractal pattern. The NPTEL logo is also present in the bottom left.

(Refer Slide Time: 00:21)

So, what I am trying planning to do in the next few lectures is to study the case of complex Tori. So, let me recall what a complex torus is.

(Refer Slide Time: 00:46)

So, if you remember we choose two complex numbers  $\omega_1, \omega_2$  which are nonzero. So, we fix this and assume that the ratio is not a real number which means there has their linear independent linearly independent over  $\mathbb{R}$ . And then we look at the subgroup of Mobius transformations which correspond to translation integer translations by integer multiples of  $\omega_1$  and  $\omega_2$ . So, you look at  $z$  going to  $n$  times, so  $z$  going

to  $z$  plus  $n$  times  $\omega_1$  plus  $m$  times  $\omega_2$  you look at all these translations by integer multiples of  $\omega_1$  and  $\omega_2$  integer linear combinations of  $\omega_1$  and  $\omega_2$ , where  $n$  and  $m$  are integers.

And this of course, these are Möbius transformations. And you see being translations the only fixed point that they have is the point at infinity. So, these are these form a subgroup of the holomorphic automorphisms of the complex plane. So, the point at infinity is mapped to the point at infinity the rest of it is going to be the complex plane, the complex plane is any finite complex number is mapped to a finite complex number. So, and you see this group this subgroup of course, is Abelian and it can be identified with  $z \mapsto z + \omega_1$ . So, in fact, I can write it like this  $z \mapsto z + \omega_1$  cross  $z \mapsto z + \omega_2$  right which is which is eventually which is actually isomorphic  $z \mapsto z$ .

And what you do is you take the complex plane alright and then you go modulo this subgroup. So, you go  $\mathbb{C}$  modulo this subgroup  $z \mapsto z + \omega_1$  cross  $z \mapsto z + \omega_2$ . And this gives you the complex structure a Riemann surface structure on the torus which we call as let me put  $T_{\omega_1, \omega_2}$ . So, these Riemann surface structure on this which is topologically a torus a real torus. And this map is a covering map which is universal covering, because  $\mathbb{C}$  is simply connected. And this covering map if it call it as  $p_{\omega_1, \omega_2}$  then this a universal covering. And because of this the fundamental group of this identified with the deck transformation group of this cover and the deck transformation group is precisely this.

So,  $\pi_1$ , so if I choose for example, point let say zero, and suppose the point zero goes to a point  $x$  here, then I have the identification fundamental group of this torus  $T_{\omega_1, \omega_2}$  based at  $x$  is identified with the deck transformation group of this covering, which is  $p_{\omega_1, \omega_2}$ . And this deck transformation group is precisely is precisely this group of translation  $z \mapsto z + \omega_1$  cross  $z \mapsto z + \omega_2$  which is exactly the same thing.

So, in fact, I should not even write isomorphic in fact, it is actually equal to. And of course, this deck transformation group which is sitting inside the group of the holomorphic automorphisms of the universal covering space, which is  $p_{\omega_1, \omega_2}^{-1} \Delta \subset \text{Aut}(\mathbb{C})$ . If you write it out as matrices these are all elements of  $\text{PSL}(2, \mathbb{C})$  with which are of upper

triangular form, fine. So, the question is we want to look at various possible Riemann surfaces that you can get in this way which to begin with, you would get by varying  $\omega_1$  and  $\omega_2$ .

(Refer Slide Time: 06:37)

So, the question is what is the set of all Tori complex Tori  $\omega_1$  and  $\omega_2$ , where  $\omega_1$   $\omega_2$  are complex numbers nonzero and with non real ratio,  $\omega_1$  by  $\omega_2$  not a not a real number. So, this a set of possible complex Tori and then you want to go you go modulo holomorphic isomorphism so that means, I am looking at holomorphic isomorphism classes of complex Tori and I want to know how many of them are there namely I want to know what is this set.

Now, well of course, the answer to this question is the following theorem, which I had stated earlier. So, let me recall this the set of a holomorphic isomorph isomorph holomorphic isomorphism classes of complex Tori is can be naturally identified with the set  $\mathcal{U} \text{ mod } \text{PSL}(2, \mathbb{Z})$ ,  $z$  which is the set of orbits of  $\text{PSL}(2, \mathbb{Z})$ ,  $z$  in  $\mathcal{U}$  in the upper half plane  $\mathcal{U}$ . This is set of all  $z$  in  $\mathbb{C}$  such that imagine it what have set is greater than 0, so that set is naturally identified viable with  $\mathcal{U} \text{ mod } \text{PSL}(2, \mathbb{Z})$ . And when you have a set modulo group what one means is of course, the orbits of the group on that side for the group acts on that set.

So, I want to tell you one thing namely recall that the holomorphic automorphisms of  $U$  are elements of  $\mathrm{PSL}(2, \mathbb{R})$ . And if  $\Gamma$  is a subgroup of  $\mathrm{PSL}(2, \mathbb{R})$ , and therefore  $\mathrm{PSL}(2, \mathbb{Z})$  also acts on  $U$ . If a group acts on set in a subgroup also acts on the set, and you can also talk about orbits for that subgroup and that is exactly what you are doing here. And the fact is that if  $\Gamma$  is the orbits, this set is exactly the set of complex Tori up to holomorphic isomorphism this, the first statement.

Then there is more interesting statement is that this set  $U / \mathrm{PSL}(2, \mathbb{Z})$  acquires naturally the structure of a Riemann surface, and that Riemann surface happens to be isomorphic that is holomorphically isomorphic to the complex plane. Further  $U / \mathrm{PSL}(2, \mathbb{Z})$  acquires naturally the structure of Riemann surface of holomorphically isomorphic to the complex plane. So, the up short of theorem is that this set is actually a Riemann surface and what is that Riemann surface is just the complex plane. So, it is amazing that this set has Riemann surface structure and that the Riemann surface is the complex plane. So, this is what I like to prove set how to prove in the next few lectures.

So, there are two tasks that we have to do. The first thing is how to identify this set with this set of orbits of  $\mathrm{PSL}(2, \mathbb{Z})$  on  $U$  that is one-step. The next step is to explain how  $U / \mathrm{PSL}(2, \mathbb{Z})$  becomes Riemann surface, and how that Riemann surface is biholomorphic that is holomorphically isomorphic with the complex plane, so this is what we are going to do. So, I will begin with trying to show this set is bijective with two mod  $\mathrm{PSL}(2, \mathbb{Z})$ . So, the first thing I want to state is that, so just for the sake of novelty note that that set of complex Tori modulo holomorphic isomorphism is also the same as well these are going to be notice let us recall theorem. If  $X$  is a Riemann surface with fundamental group isomorphic to  $\mathbb{Z} \times \mathbb{Z}$ , then  $X$  has to be complex to us. So, there is a theorem that we have proved.

So, I can just write this also as a set of I mean well I should not write set of and also put a bracket, but let me not be too pedantic about this. So, let me just say, so I hope it is all right. So, let me clear, let me rub this. So, here I can also write as Riemann surfaces  $X$  with  $\pi_1(X, x_0)$  isomorphic to  $\mathbb{Z} \times \mathbb{Z}$ , base point does not matter isomorphic to  $\mathbb{Z} \times \mathbb{Z}$  modulo holomorphic isomorphism. One can also state like this. You are looking at all those Riemann surfaces with fundamental group isomorphic to  $\mathbb{Z} \times \mathbb{Z}$ , and your studying them up to holomorphic isomorphism. In this sense what you are doing is well you are looking at various possible Riemann surface structures that you can put on a real

torus, the underlying structure is topological real torus. And then you are looking at various Riemann surface structures that you can put on this and trying to look at how many non isomorphic structures you get.

So, there is an underlying structure which is the structure of the real torus. And there is a super imposed structure which is that of a Riemann surface. And the question is how many extra structures can you give for the same underlying structure. So, this is exactly what is called a moduli problem in a simplest form. You have a fixed structure on an object and then you know that you can put an extra structure on it, the question is how many extra structures on isomorphic extra structure that we can put on that, and if you look at the set of all those structures that have a geometry that is a question of modulo. And we get a beautiful theorem in the case of complex Tori. So, this is the first case where you get a beautiful theorem on moduli. So, this toned was just for just fun.

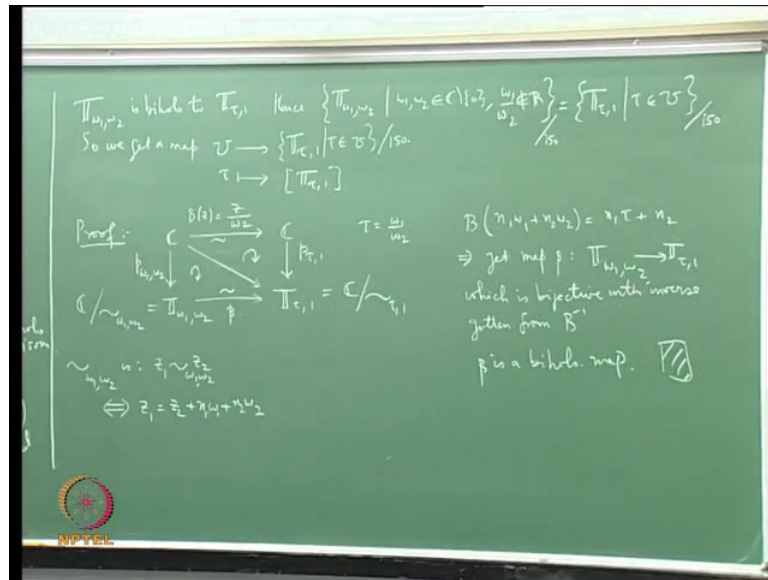

Now, well now I am going to do make a small, so the first thing is where does the upper half plane come into the picture. So, you can ask this question where does the upper half plane come into the picture it comes because of the following things because you can given any torus like that you can normalize it. So, here is a lemma, the lemma is  $T$  you take this torus  $T$   $\omega_1$  comma  $\omega_2$ , this is biholomorphic that is holomorphically isomorphic to the torus  $\omega_1$  by  $\omega_2$  comma 1, so which means I literally have these two complex numbers I divide throughout by  $\omega_2$ . So, the second one becomes one the first one becomes  $\omega_1$  by  $\omega_2$ . And in the same way is also biholomorphic to well the torus  $T$  of well  $\omega_2$  by  $\omega_1$  comma 1 of course, I could have divided by  $\omega_1$ .

So, now what I wanted to tell you is that, so I want to tell you what this lemma means with respect to  $U$ , you see  $\omega_1$  by  $\omega_2$  is not real is an non real ratio. So, it is a complex number it has an imaginary part. And then if you take the imaginary part, then either  $\omega_1$  by  $\omega_2$  or  $\omega_2$  by  $\omega_1$  has an imaginary part which is positive. And then you choose the one that has imaginary part positive and call that as  $\tau$  and then that  $\tau$  is an element of  $U$ . So, what I am trying to say is that choose  $\tau$  to be well  $\omega_1$   $\omega_2$  or  $\omega_2$  by  $\omega_1$ , so that real the imaginary part of  $\tau$  is positive. You can do that, and in one of them has to have if one of them has a imaginary part negative, then the other one will have imaginary part positive.

So, what is going to happen you choose the one it has imaginary part positive. Then you have tau in the upper half plane and T omega 1 comma omega 2 is biholomorphic to may does not enough space. Here let me write it in the next board then tau belongs to u.

(Refer Slide Time: 18:50)

And the torus T omega 1 T omega 2 is biholomorphic to well T tau comma 1. So, the moral of the story is that instead of looking at all possible Tori like this, it is enough to normalize these two complex numbers in such a way that one of them is in element of the upper half plane and the other one is 1. So, what this lemma is says is that it is enough to look at T tau comma 1 with tau in u that is all, with tau in U. So, real part of tau is greater than 1.

So, what is the up short let me write that down hence set of T omega 1 comma omega 2, well omega 1 comma omega 2 in nonzero complex numbers omega 1 by omega 2 not real is exactly the same as the set of T tau comma 1 that tau is in U. So, so it is enough to look at only complex Tori of this form up to isomorphism. So, in fact maybe I should not I should not write like this I should write mod isomorphism, so mod isomorphism is equal to this mod isomorphism in fact, should write mod isomorphism not exactly set theoretically. So, instead of looking at isomorphism classes here I can also look at isomorphism classes here.

Now, what is the proof for this lemma the proof of this lemma, so that is where you comes into the picture that is where you comes into the picture. So, in fact, what is happening is that you, so we have, so let me write that down. So, we have actually a map. So, we get a map from  $U$  to the set of all Riemann surfaces, I mean set of all complex Tori mod isomorphism namely you just sent out to the isomorphism class of  $T$   $\tau$  comma 1. So, you have map like this. And now you know what it is that you are trying to prove, we are just trying to prove that this map factors to  $U$  to the quotient  $U$  mod  $PSL$  to  $z$  which is the orbits of  $PSL$   $2$   $z$  in  $U$ . And when it factors it gives raise to bijective map with this that will tell you that the set of isomorphism classes of complex Tori is naturally identifiable with the orbits of  $PSL$   $2$   $z$  on the upper half plane.

Well, so let us give the proof of the lemma; it is pretty easy to prove. So, what we have is well. So, let me write out the universal coverings for these two. So, I have  $C$  to well I have this projection  $\omega$  1 comma  $\omega$  2, then here I have the torus complex torus defined by  $\omega$  1 and  $\omega$  2. And I have on the other hand  $C$  to that is this projection  $\tau$  comma 1, and I have the complex torus  $\tau$  well  $\tau$  comma 1, where  $\tau$  is where let me take  $\tau$  to be  $\omega$  1 by  $\omega$  2, if you want to. Because I could have also equally taken  $\tau$  is equal to  $\omega$  2 by  $\omega$  1.

Now, what you do is define this map  $B$  of  $z$  is well  $z$  by  $\omega$  2. Look at this map  $\phi$  of  $z$  is equal to  $z$  by  $\omega$  2 now that map I can divide by  $\omega$  2 because  $\omega$  2 is not zero. And then it is going to take the complex plane out of the complex plane, it is a Mobius transformation and it has, so it is a holomorphic automorphism of  $C$  it is a holomorphic automorphism of  $C$ . And let us see what it does see notice that this just  $c$  mod an equivalence relation which is this the equivalence relation is, so this there is an equivalence relation let me put it equivalence sub  $\omega$  1 comma  $\omega$  2. And what is this equivalence sub  $\omega$  1 comma  $\omega$  2 is you see  $z$  1 is equivalent under this under this relation to  $z$  2 if and only if  $z$  1 is  $z$  2 plus an integer linear combination of  $\omega$  1 and  $\omega$  2 let me say  $n$  1  $\omega$  1 plus  $n$  2  $\omega$  2. And this is exactly the equivalence. I mean this another way of saying that you are going modulo translations by integer multiples of  $\omega$  1 and  $\omega$  2.

And well and you have a similar statement here this is the complex plane modulo the equivalence relation given by  $\tau$  comma 1. And well the definition is similar to this. And now what I want you to understand is that what does  $B$ ; do to a point like this. If you

remember these were points of these were the points were grid of parallelograms. And we were actually going modulo that grid and see what  $B$  does to a point like this  $B$  takes  $n_1 \omega_1 + n_2 \omega_2$  to well I do be is supposed to the division by  $\omega_2$ . So, what I am going to get, I will get  $n_1 \tau + n_2$ , I will get  $n_1 \tau + n_2$ .

But  $n_1 \tau + n_2$  is a point of this grid. The grid here is the grid which is given by  $\tau$  and one. You form a parallelogram with just one and  $\tau$ , and then repeat this parallelogram you get a grid of parallelograms, and the end points of the grids vertices of the grid are precisely these elements of this form. So, what  $B$  does is it takes this grid to that grid. And because of the fact that these are just because of the fact that these are equivalence relations modulo going modulo those grids, you are going to get a map like this. I am going to get a  $\beta$ ; I am going to get a  $\beta$  such that this diagram commutes. So, this implies that at a set theoretically set theoretically I am going to get a map  $\beta$  get map  $\beta$  from this torus with torus.

Now, the point I want to make is that of course, this map is bijective map, because I have  $B$  inverse, these isomorphism  $B$  inverse will be multiplication by  $\omega_2$ . So,  $B$  inverse will also map a point like this to a point like this that will also take this grid here to the grid here. So,  $B$  inverse is going to induce an inverse  $\beta$ . So,  $\beta$  is actually a bijective map, so which is bijective with inverse gotten from  $B$  inverse in exactly the way we got the  $\beta$  from  $B$ . So, I get a bijective. Now, I want to say that this bijective map is actually biholomorphic map. So, why is it biholomorphic, it is biholomorphic for the following reason.

So, let me break this diagram into two commutative diagrams. So, this  $B$  followed by  $\beta^{-1}$ , this is holomorphic, and this is holomorphic. Mind you the holomorphic structure on this was inherited from the holomorphic structure above, and once you fix this holomorphic structure this covering projection becomes a holomorphic map, it is a covering in the holomorphic sense. Therefore, this is holomorphic, this is holomorphic therefore, this is holomorphic and this map is a covering map. So, it is locally invertible it is locally holomorphic.

Therefore, this followed by this local, but then again this is also a composition of holomorphic maps. And therefore, this is holomorphic. So, the moral of the story is that the map  $\beta$  is holomorphic. So, it is an injective holomorphic map. So, it is a

biholomorphic map. So, beta is a biholomorphic. And this literally tells you that this torus and this torus are holomorphically isomorphic. So, it is very simple lemma. So, the advantage as I told you this lemma is that it is enough to look at only Tori which are given by points on the upper half plane.

Now, let me go ahead and try to say that we get an identification of these isomorphism classes of this set of isomorphism classes of these Tori with  $u \text{ mod } \text{PSL } 2 \text{ c}$ . So, well, so suppose, so let me start the argument like this, because I think it will be very ideal for the exposition yes correct.

(Refer Slide Time: 30:43)

So, suppose the isomorphism class of  $T \tau_1 \text{ comma } 1$  is equal to the isomorphism class of  $T \tau_2 \text{ comma } 1$ , where  $\tau_1$  and  $\tau_2$  are the (Refer Time: 31:06), suppose they are isomorphic. So, this means that the torus defined by  $\tau_1$  isomorphic holomorphically isomorphic torus it defined  $T \tau_2$ . Now, again let us draw the covering maps. So, I have  $\mathbb{C}$ . So, I have this  $p_1$  and this  $T \tau_1 \text{ comma } 1$  then I have again  $\mathbb{C}$ , this  $p_2$  and I will have  $T \tau_2 \text{ comma } 1$ . And since it is given that these two are holomorphically isomorphic let me choose an isomorphism, let me call it something let say  $f$ . So, I am given the holomorphic isomorphism  $f$  between these two torus. And what I am going to do is using this and covering space theory I am going to cook up an element of  $\text{PSL } 2 \text{ c}$  that moves  $\tau_1$  to  $\tau_2$  that is what I am going to do.

So, how I am going to do this? So, you see because of this map, so let us look at this whole diagram. The first thing is as we have done in the case of as we have done earlier see if I take this composition writing this composition, this is a holomorphic isomorphism this, the covering. Therefore this continuous to be a covering. So, this is just  $p_1$  followed by  $f$  that is what this and this also a covering. And you know by the universal property, universal lifting property lifting property is of coverings this lifts to a map here.

So, for that I will have to do some work I will have let me choose  $0$  here and let us assume that  $0$  goes to let us say a point  $x_1$  here. And let me assume that  $f$  of  $x_1$  go  $f$  takes  $x_1$  to  $x_2$  and let me fix a point, let me call this as well I do not even need to put  $0$  may be I put  $z_1$ . Let me call this as  $z_2$ , fix a point  $z_2$ , which goes to  $x_2$  under. So,  $p_1$  takes  $z_1$  to  $x_1$   $p_2$  takes  $z_2$  to  $x_2$   $f$  takes  $x_1$  to  $x_2$ . And I can lift this  $f \circ p_1$  to a map  $f \circ p_1 \tilde{\phantom{p_1}}$  which I would like to call as let me call this as  $B$  such that this diagram commutes. And well this map  $B$  is going to be holomorphic isomorphism because I can construct an inverse, I can construct the inverse simply by taking  $f$  inverse just as I got  $B$  from  $f$ , I will get  $B$  inverse by looking at  $f$  inverse because  $f$  is an isomorphism.

So, well  $B$  is an element of it is a holomorphic automorphism of  $C$ , so element of an  $p_1$   $\Delta_2$ ,  $C$ . So,  $B$  can be identified with you can give it a matrix representative in  $PSL_2 \mathbb{C}$  namely  $\begin{pmatrix} a & b \\ 0 & d \end{pmatrix}$  and it is in  $PSL$ . So,  $a d$  is  $1$ , so  $d$  is  $1$  by  $a$ . So,  $B$  will look like. So, this will be just look like  $\begin{pmatrix} a & b \\ 0 & 1 \end{pmatrix}$  by  $a$ . And of course, so this means that  $B$  is a Mobius transformation  $B$  of  $z$  is equal to  $a z$  plus  $b$  by  $0 z$  plus  $1$ , which is how all automorphisms of holomorphic automorphisms of  $p_1$  look like.

Now, one is to look at what is happening to the deck transformation group because of this. So, this is a map this a whole diagram of spaces. You know that forming the fundamental group is factorial. So, I am going to get a corresponding diagram for the fundamental groups. So, let me write that down. So, what I am going to get is I will have here the fundamental group, first fundamental group of this torus based at  $x_1$  that is going to identified with the deck transformation group of this covering, which is deck of  $p_1$ . And this  $f$  is going to give me an isomorphism  $f$  lower star which is you know take a loop at  $x_1$ , you can produce a loop at  $x_2$  which is just well you take just take the image

of this loop there, and do this for homotopy classes. So, this fundamental group is what you get naturally because the formation of the fundamental group is factorial.

And here what I will get here is fundamental group of this the other torus  $T^2$  based at  $x_2$ , and that is well identified with the deck transformation group of  $p_2$ . And you have also one more, there is also a map like this. So, this also a covering; because of this covering I will get an identification of this the fundamental group of this namely this with the deck transformation group of this cover, but then followed by this is this. So, what will actually tell me is that this same as the deck transformation group of  $f \circ p_1$ , these will be one and the same. This is for example, I prove this explicitly in the previous lecture.

So, this is another identification, this identification comes because of this covering; and because this diagram commutes this diagram also commutes and that is the reason why these are the same and what about this map. So, this map is just you know conjugation. Namely, if you give me deck transformation here how do I get a deck transformation there? What I do is I go like this apply the deck transformation and then come back going like this applying  $B^{-1}$  then applying the deck transformation here and then applying  $B$ . So, it just the map that sends  $A$  to  $B$   $A B^{-1}$  is just conjugation by the and this is an isomorphism because this map is an isomorphism this a holomorphic isomorphism. So, well, so the up short of all this the following I have  $d \cdot \text{deck } p_1 B^{-1}$  is equal to  $\text{deck } p_2$ . Namely, the deck transformation group of  $p_1$  and  $p_2$  are deck, they conjugates in the group of holomorphic automorphisms of  $C$ . So, I get this.

(Refer Slide Time: 39:49)

Now, let us go and look at what the generators of this of these deck transformation groups we chosen as and will get a little bit more we can exactly little bit more of information. So, well, so we have see deck p 1 the deck transformation group of p 1 is has generators  $z$  going to  $z$  plus 1  $z$  going to  $z$  plus tau 1. So, these are the generators of deck transformation group, after all the deck transformation group is precisely the sub group of holomorphic automorphisms that you have to go mod to get this torus and sub group of holomorphic automorphisms here are translations by integer multiples of tau 1 and 1. So, you get this. And similarly deck p 2 has generators  $z$  going to  $z$  plus 1,  $z$  going to  $z$  plus tau 2. Notice that these two are they are isomorphic to the corresponding fundamental groups in the fundamental groups such as  $z$  cross  $z$ , therefore, there are two generators.

Now, you see, so if you look at this, what this will tell you is that if I take  $z$  going to  $z$  plus 1, then it is a conjugate of an element here and similarly  $z$  going to  $z$  plus tau 2 is a conjugate by  $B$  of an element here. So, let me write down what I worked out. So, well, so you can write  $z$  going to  $z$  plus 1 is equal to  $B$   $z$  going to  $z$  plus alpha tau 1 plus beta dot  $B$  inverse and  $z$  going to  $z$  plus tau 2 is  $B$  dot conjugation by  $B$  of  $z$  going to  $z$  plus gamma tau 1 plus delta dot  $B$  inverse. Where alpha, beta, gamma, delta are integers. After all you see if you take  $z$  going to  $z$  plus 1 it is conjugate by  $B$  if an element here, but how does an element here look like it is translation by an integer multiple of 1 and tau 1. So, it will look like this. Similarly,  $z$  going to  $z$  plus tau 2 is going to look like

conjugate by B of an element here, which I have taken it in this form that is why you get this four integers, you get these four integers. And you can guess that they are going to give you the element of  $PSL(2, \mathbb{Z})$ , so that is a calculation that one has to do.

So, let me write it down. So, what happens is if you write it down this is what you get. So, you see suppose I write it in matrix form this  $\begin{pmatrix} 1 & 1 & 0 & 1 \\ 0 & 1 & \alpha & \tau \end{pmatrix}$  is equal to  $B \begin{pmatrix} 1 & 0 & 1 \\ 0 & 1 & \beta \end{pmatrix}$  I mean this I just this written in matrix form I have just pushed this B inverse to B on the right; I have multiplied both sides of the equation on the right by B. And if I write it in the matrix forms what I get. Similarly, if I do it in the second equation what I will get is I will get one  $\tau^2 = 0$ , B is equal B well is equal to B times the low one which is  $\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$  gamma tau 1 plus delta, I get this.

If you write out, if you make the comparisons and write out, you will see that this is true these two are true. So, this is true if and only if you will see that b is equal to 0 and you get  $\alpha\tau + \beta = 1$  by a square, where you know this a was this a that we chose for the matrix representative of B and  $PSL(2, \mathbb{C})$ . And here you will get these two are equal I mean this equivalent to well again of course, B is 0 and you will get  $\tau^2$  by a square is equal to  $\gamma\tau + \delta$ , this is what you get.

Now, you can see immediately that you know if I write if I eliminate a square, what I am going to get is I am going to get  $\gamma\tau + \delta$  by  $\alpha\tau + \beta$  is equal to  $\tau^2$ . So, what we have gotten is an element of  $PSL(2, \mathbb{Z})$ , z which is moving  $\tau_1$  to  $\tau_2$ . Now, there is a point here there is a check that has to be done to say that  $\gamma\beta - \alpha\delta$  is actually equal to 1. One has to for example, even verify that this really a Mobius transformation one has to really verify that  $\gamma\beta - \alpha\delta$  is equal to one is for example, if not equal to 0.

So, how does one do that? So, the claim is  $\gamma\beta - \alpha\delta$  is actually equal to 1. So, for this it is enough to prove that  $\gamma\beta - \alpha\delta$  is nonzero. See  $\gamma\beta - \alpha\delta$  is not zero, it is an integer and it is it has to be invertible, because it is an determinant of an integer matrix, it has to be an invertible integer. So, if you prove  $\gamma\beta - \alpha\delta$  is not zero, then you will get  $\gamma\beta - \alpha\delta$  equal to plus or minus 1, then I will have to eliminate the case that it is minus 1. And eliminating the case that is minus 1 is precisely where I am

going to use the tau 1 and tau are have real part I have I have imaginary part greater than zero which is very very direct calculation.

(Refer Slide Time: 46:56)

So, let me explain. So, let me write down that calculation. So, suppose it is 0, I mean I am trying to give a very elementary argument, suppose gamma beta minus delta alpha is 0. Then what you do is you use these two equations, you use these two equations and try to use the fact that so you know I multiply this equation by delta. So, I can get delta alpha. Then I multiply this equation by beta, so that I can get a beta gamma and then if I subtract alright then this delta alpha tau 1 minus is beta gamma tau 1 is going to go away.

And if I do that what I am left out with is zero equal to beta tau 2 minus delta by a square this is what I will get. Multiply this equation by delta, multiply this equation by beta and then subtract you will get this. And you have use gamma beta minus delta alpha is zero you will get this. But this will tell you that you know beta tau 2 is delta which is impossible, because you see beta is an integer, delta is an integer, tau is a complex number. It will tell you that tau 2 is equal to for example, if beta is not zero it will tell you that tau 2 is a rational number, a real number for that matter it is which it is not because tau 2 is imaginary. So, this will imply the only way is beta is equal to delta is 0, there is no other way.

But you see if beta is equal to delta is 0, see for example, you know if beta is equal to 0 then alpha is not, if beta is 0, alpha tau 1 is 1 by a square that is not 0. So, alpha is not 0. And what you will get if I put it here I will get gamma. So, I will get alpha is not 0 and tau 1 is equal to 1 by alpha a square. And if I put it back into this, and use the fact delta is 0, I will end up with getting gamma by alpha is equal to tau 2. So, I just delta is 0, I cross multiply these a square and a square tau 1 I write it as 1 by alpha then I will get gamma by alpha is equal to tau 2 which is again non zero. Because you see now tau 2 becomes the rational number gamma and alpha are integers, so that is not possible absurd. So, it is a very elementary argument to show that alpha gamma beta minus delta alpha is nonzero. So, gamma beta minus delta alpha is not equal to 0.

So, now we need to see why gamma beta minus delta alpha is actually equal to 1. So, for that what one needs to do is to look again to look again at this diagram here, one has to look at this diagram here and look at it carefully. The first thing that we should remember is that both deck transformation groups you see they are you know they can be identified as  $\mathbb{Z}$  modules with complex numbers. So, what you can do? So, one can write down the following. So, let me write down that diagram again.

(Refer Slide Time: 50:57)

So, I have deck p 1 right point here then I have this isomorphism, which is conjugation by B this just the map a going to B A B inverse. And this is an isomorphism of that of the deck transformation group of the covering given by p 1 with the deck transformation

group of the covering given by  $p_2$ . And well you see this deck transformation group can be identified you see with this is an isomorphism with  $\mathbb{Z}$ . So, let me follow the follow what I have written down  $\mathbb{Z}$  one are cross  $\mathbb{Z}$   $\tau_1$ .

So, what I am doing here is an element here is translation by an integer multiple of one and an integer multiple of  $\tau_1$ . So, it is given by two a pair of integers and I am just identifying that with these two integers here. So, there is an isomorphism like this that makes a so this isomorphism actually shows that this a  $\mathbb{Z}$  module this is an isomorphism with  $\mathbb{Z}$  modules. So, similarly, I have an isomorphism here, this isomorphism will be in  $\mathbb{Z}$  it go to  $\mathbb{Z}$   $\tau_1$  cross  $\mathbb{Z}$   $\tau_2$ . Of course, this because of this you see this deck  $p_1$  has generators  $z$  going to  $z + 1$  and  $z$  going to  $z + \tau_1$  and deck  $p_2$  has generators  $z$  going to  $z + 1$  and  $z$  going to  $z + \tau_2$  it is only. And you see these are generators as  $\mathbb{Z}$  modules. So, you have this identification.

Now, if you look at one would like to look at this map which is given by the commutativity of this diagram. So, well notice that this map is conjugation by  $B$  it has an inverse the inverse map is just conjugation by  $B^{-1}$ , obviously and this conjugation by  $B$  induces let me call this map, so mind you this map is also going to be an isomorphism it will be an isomorphism of  $\mathbb{Z}$  modules. This is also an isomorphism. And I will get.

So, this let me call this as  $\gamma$  prime and then I will have map like this. So, the conjugation by  $B^{-1}$  is going to induce  $B$  like this, namely this map is this followed by this followed by this that is this map; and this map is this followed by this followed by this. So, I have these  $\gamma$  and I have  $\gamma$  prime, and it is obvious that you know  $\gamma$  and  $\gamma$  prime are  $\mathbb{Z}$  module homomorphisms and they are inverses of each other  $\gamma$ ,  $\gamma$  prime are  $\mathbb{Z}$  module homomorphisms; and of course,  $\gamma$  prime is  $\gamma$  inverse by the very way it is defined.

Now, the important thing is what is the matrix for  $\gamma$ . See  $\gamma$  is the map from two copies of  $\mathbb{Z}$  two copies of  $\mathbb{Z}$ . So, it is given by a  $2 \times 2$  matrix with integer in  $\mathbb{Z}$ . And what is that map, and that map is see claim is this  $\gamma$ , so let us calculate. So, take the element one here take the element one here, see this I need to know what where  $\gamma$  of one goes to, so take the element one here this element one is a identified with the transformation  $z$  going to  $z + 1$ . And that transformation will go to  $B^{-1} \cdot z$

going to  $z + 1 \cdot B$ , and then I am going to identify it with this. But what is go back to this equation here  $B^{-1} \cdot z$  going to  $z + 1 \cdot B$  is actually  $z$  going to  $z + \alpha \tau + 1 \cdot \beta$ .

So, when I come here, I will get the map  $z$  going to  $z + \alpha \tau + 1 \cdot \beta$ . And if I bring it down here I will get the elements  $\alpha$  times one plus  $\beta$  times  $\tau + 1$ , so I basically get  $\alpha$  comma  $\beta$ . So,  $\gamma$  of 1, if you want what I mean by that is  $\gamma$  of one comma 0, you take one here you take 0 there alright. This is  $\alpha$  comma  $\beta$  and what is  $\gamma$  of 0 comma  $\tau + 2$ , what is  $\gamma$  of 0 comma  $\tau + 2$ . See take  $\tau + 2$  here it will go to the deck transformation which is translation by  $\tau + 2$ , so it will go to  $z$  going to  $z + \tau + 2$  alright and here it will go to it is conjugate by  $B^{-1}$ . So, namely I will get  $B$ . So, now, go back to this diagram see  $B^{-1} z$  going to  $z + \tau + 2 \cdot B$  is actually  $z$  going to  $z + \gamma \tau + 1 \cdot \delta$ .

So, the image of  $\tau + 2$  here will be the translation by  $\gamma \tau + 1 \cdot \delta$ . And you see if I take its image here I am going to end up with  $\delta$ , so it is  $\delta$  comma  $\gamma$  is  $\delta$  comma  $\gamma$ , if I write it in this order  $\gamma + \delta \tau + 1$ , that is what it is. So, you see what the this tells you that matrix of  $\gamma$  is  $\alpha \beta \delta \gamma$  and I think I am not writing it correctly. So, it is  $\alpha$  times wait a minute,  $\alpha$  is coefficient  $\tau + 1$ , so  $\beta \alpha$  I should write it here also. It  $\beta$  times one plus  $\alpha$  times one, it is  $\beta$  this the matrix of  $\tau$ .

And you see for  $\gamma'$  also, similarly you will get an integer entries. And what will happen is you see the whole point is  $\gamma$  and  $\gamma'$  are isomorphisms their  $z$  module isomorphisms. So, the fact is so, let me write this here  $\beta \alpha \delta \gamma$  times let me write matrix of  $\gamma'$ ; if I compose, I should get the identity matrix. And this is I get this because these this the inverse of  $\gamma'$   $\gamma$  is the inverse of  $\gamma'$  that is right  $\gamma'$  inverse is  $\gamma$ ,  $\gamma$  inverse is  $\gamma'$ .

So, I get this. And the matrix of  $\gamma'$  will also have integer entries I mean it is you have to write the same way as you wrote  $\gamma$ . But in any case what will happen is see this is the equation that helps me because now if I take determinant if I take determinant and notice that all my calculations are happening in  $z$ , they are happening in  $z$  the integers.

(Refer Slide Time: 59:24)

So, if a determinant I will get what I will get is a I will get beta gamma minus delta alpha times determinant of matrix of gamma prime is equal to 1. Now, you see I get a product of two integers equal to 1. So, the possibility is that either both are plus 1 or either or both are minus 1. So, this will tell you that beta gamma minus delta alpha is equal to plus or minus 1. Now, of course, one can rule out the case that beta gamma minus delta alpha is minus 1 because of the condition that tau 1 and tau 2 have imaginary part positive that is that is because of the following calculation.

So, let me write that down. So, here I am. So, if I calculate imaginary part of tau 2 it is by definition imaginary part of well tau 2 is now going to be I have a written it there, I have written it here, tau 2 is gamma tau 1 plus delta by alpha tau 1 plus beta. So, gamma tau 1 plus delta by alpha tau 1 plus beta, this is what it is. And you write the imaginary part of this as this minus its conjugate divided by 2 y, you just write it out. And if you simplify it what you will end up with this you will get delta alpha minus beta gamma times minus of imaginary part of tau 1 divided by modulus of alpha tau 1 plus beta the whole square this is what you will get. If you make a very simple calculation, you will get this.

And you will see that you see the imaginary part of a tau 2 is positive, imaginary part of tau 1 is positive, and this quantity is also positive. Therefore you see this quantity has to be negative. So, this will tell you imaginary part of tau 1, imaginary part of tau 2 positive

will tell you that  $\delta\alpha - \beta\gamma$  has to be minus 1, so that will tell you that well as we wanted  $\gamma\beta - \delta\alpha$  is equal to plus 1 is equal to 1. So, this confirms that you know this matrix, so this means that your matrix  $\gamma$  is actually an element of  $PSL(2, \mathbb{Z})$ . So,  $\gamma$  is an element of  $PSL(2, \mathbb{Z})$ , it is a element of  $PSL(2, \mathbb{Z})$  and you can take the image defined take it is image in the quotient group  $PSL(2, \mathbb{Z})$ .

Well, let us consider this namely the following thing  $\gamma\delta\alpha\beta$ , this is an element of  $PSL(2, \mathbb{Z})$ , this is also an element of a  $PSL(2, \mathbb{Z})$ . Again you see this takes  $\tau_1$  to  $\tau_2$  that is what I want. So, well if I chosen these constants correctly, I would have directly got the  $\alpha\beta\gamma\delta$ , but any way it does not matter. So, the point is I got an element of  $PSL(2, \mathbb{Z})$  which takes  $\tau_1$  to  $\tau_2$ . So, the up short of the story is if the torus complex torus is defined by  $\tau_1$  in the upper plane is isomorphic to the complex torus defined by  $\tau_2$  in the upper half plane, then there is an element of  $PSL(2, \mathbb{Z})$  which takes  $\tau_1$  to  $\tau_2$ .

Now, the point is that this whole argument can be reversed. Conversely, if I am given a  $PSL(2, \mathbb{Z})$  element which takes  $\tau_1$  to  $\tau_2$ , then one can work out and one can so in that case you know  $\alpha\beta\gamma\delta$  are given integers such that you know  $\gamma\beta - \delta\alpha$  is equal to one and given this. So, in some sense, so I am given  $\gamma$ ; and from  $\gamma$  I have to cook up, I have to cook up an isomorphism, I have to cook up an isomorphism between these two Tori. And how do I do this?

Well, I am given this  $\gamma$ , what I can do is first I can first cook up, this I can cook up this  $B$ , which is given by the quotient. And how do I get these quotients, well you see I set if you go back here I set small  $b$  equal to 0, and then I set  $a$  to be as square root  $1$  by  $\alpha\tau_1 + \beta$ . So, I set  $a$  like that. And then I consider this transformation  $\begin{pmatrix} a & 0 \\ 0 & d \end{pmatrix}$  and instead of  $d$  I put one by  $a$  that will give me Mobius transformation  $B$ . And that Mobius transformation you can check will give me a map that will give me an isomorphism from  $C$  to  $C$ .

Now that isomorphism because of that isomorphism that isomorphism will actually go down. The reason why it will go down is because the lattice defined by  $1$  and  $\tau_1$  namely the  $\mathbb{Z}$  sub module of  $\mathbb{C}$  defined by  $1$  end  $\tau_1$  will be mapped to the  $\mathbb{Z}$  sub module  $C$  defined by  $1$  end  $\tau_2$ . That is because of the way that is because you are given that element of  $PSL(2, \mathbb{Z})$ , which does this. Therefore, this you will get this  $B$ , and it will go

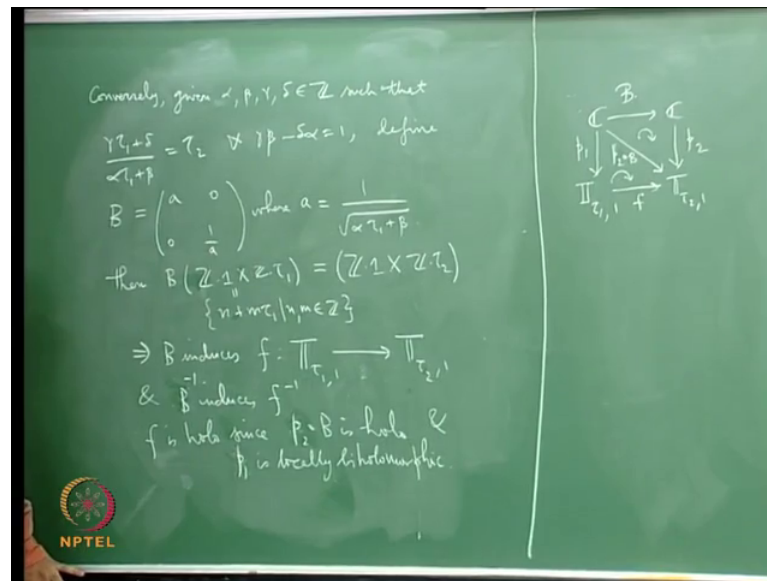

down to a map like this. You can cook up the  $B$  given  $\alpha$   $\beta$   $\gamma$   $\delta$  and  $PSL_2$  matrix, which takes  $\tau_1$  to  $\tau_2$  namely for which this holds I can write down this explicitly.

All I have to do is I have to set small  $b$  is equal to 0; I have to take instead of  $d$  of course, I have to put 1 by  $a$ . And for  $a$ , I have to take just square root of 1 by  $\alpha \tau_1$  plus  $\beta$  that is all I can that is all I have to do. And then I will get this  $B$  and you can check that this  $B$  takes any integer linear combination of  $\tau_1$  and 1 into an integer linear combination of  $\tau_2$  and 1 that is because of the way that is because of the unimodular transformation  $\alpha \beta \gamma \delta$  that is already given to us.

So, you will see that it will carry grid defined by 1 and  $\tau_1$  to the grid defined by 1 and  $\tau_2$ . And therefore, you know it will induce the map like this and the  $d$  inverse will induce the map in the other direction. So, the map will be automatically bijective. The only question is why is it holomorphic isomorphism it is very simple because you see what will happen is well if I am given  $B$  then  $B$  for this of course, holomorphic it is a it is a Mobius transformation, then this also holomorphic. Therefore, this becomes holomorphic.

Now, this map is because this a covering this map is locally this followed by this because you see this map  $p_1$  is a local homeomorphism it is a local biholomorphism. So, locally this map can be written as inverse of this followed by this by taking an admissible neighborhood at any point. So, this map becomes a composition of two holomorphic map. So, therefore, this becomes holomorphic in the similar way it is inverse also becomes holomorphic therefore, these two Tori becomes isomorphic biholomorphic. So, everything can be the whole argument can be reversed the whole argument can be reversed. So, the up short of the story is a following result.

(Refer Slide Time: 68:23)

So, let me write that down. So, let me write this, just for the sake of completeness. Conversely given alpha, beta, gamma, delta integers such that gamma tau 1 plus delta by alpha tau 1 plus beta is equal to tau 2 and well gamma beta minus delta alpha is equal to 1. Define B by a 0 0 1 by a, where a is just given by this formula 1 by root of alpha tau 1 plus beta then B induces then B takes z dot 1 cross z dot tau 1, it takes this subset of complex numbers.

So, this is set of all complex numbers your integral multiples of 1 and tau 1. So, it is of the form n plus n plus m tau 1. So, this will go into z dot 1 cross z dot tau 2. So, this will imply B induces f from the torus defined by tau 1 to the torus defined by tau 2. And B inverse of course, B inverse induces f inverse. The only thing that is left is this see that f is holomorphic that is because f is holomorphic since. So, let me draw again draw a small diagram and rub this side.

(Refer Slide Time: 71:03)

So, let me draw the diagram and then come back here. So, I have  $C \rightarrow C$ , I have  $B$  and this  $p_1$ , this is a covering projection for torus defined by  $\tau_1$ . And this  $p_2$  the covering projection defined by torus defined by  $\tau_2$ . And this my  $f$  and this diagram commutes. And well this map is going to be the  $p_2 \circ p_1^{-1} \circ f$  that is what this map. So, it is this followed by this. And well of course, this diagram also commutes. So, what I am going to say is that  $f$  is holomorphic since  $B \xrightarrow{p_2} C$  is holomorphic, this is holomorphic, because it is a combination of holomorphic and because  $p_1$  is locally biholomorphic and  $p_1$  is locally biholomorphic. Therefore,  $f$  is an injective holomorphic map. So, it is a biholomorphic map. And therefore, we have proved that the Tori are isomorphic.

So, you see therefore, the moral of the story is that what I can do is from  $U$  to the set of all complex Tori isomorphic class of Tori which was of the form  $T_{\tau, 1}$ ,  $\tau$  belonging to  $U$  mod isomorphism. I have this map  $\tau$  being sent to  $T_{\tau, 1}$  isomorphism class biholomorphic class holomorphic isomorphism class. Then this map goes down to a map to the quotient  $U \text{ mod } \text{PSL}(2, \mathbb{Z})$ . So, I have the quotient  $U \text{ mod } \text{PSL}(2, \mathbb{Z})$ , this is the set of orbits of  $\text{PSL}(2, \mathbb{Z})$  on the upper half plane. And well two points go to the same point here if and only if they are moved movable by an element of  $\text{PSL}(2, \mathbb{Z})$  that is what we have proved. So, you get a map like this, you get a map like this.

Now, this map is of course, by definition surjective, therefore, this also surjective and it is also injective because for the simple reason that you know if you have  $\tau_1$  and  $\tau_2$  which give rise to isomorphic Tori then  $\tau_1$  and  $\tau_2$  have to be in the same orbit of  $PSL(2, \mathbb{Z})$ ; so this also this as this injective as well as surjective, so this bijection. So, you see this completes the proof of this fact that the set of isomorphism classes holomorphic isomorphic classes of complex Tori is bijective to this set namely the sets of set of orbits of  $PSL(2, \mathbb{Z})$  in  $\mathbb{H}$ . So, this is the first part of this story.

Now, what we need to do in the next what we will do in the next lecture is to show that this a Riemann surface, you have to show that this is Riemann surface. And that this map this bijective map, one wants to show that this Riemann surface and one also wants to show that this actually and Riemann surface that it is actually the complex numbers that is what one wants to say show, so that is the next part of the story.

So, we will continue in the next lecture.
