Lecture – 30

**The Uniqueness Property of the Weierstrass Phe-function associated to a Lattice in
the Plane**

(Refer Slide Time: 00:09)

(Refer Slide Time: 00:18)

So, in the last lecture, I was trying to convince you that we will have to study meromorphic functions on the torus which are especially the simplest of which are you know a function which has pole at only one point which is a pole of order 2 and so, let me let me go back and write down; I will just recollect what I told you last time, but the purpose of this lecture is to actually show that the that is essentially only one normalized. So, to say type of elliptic function on a torus, which is exactly the Weierstrass p-function. So, let us again recall.

(Refer Slide Time: 01:36)

$$\begin{array}{ccc} \tau \in \mathcal{U} & & \\ \downarrow & & \\ \mathcal{U}/\text{PSL}(2, \mathbb{Z}) & \xrightarrow{f} & \mathbb{C} \\ \tau \rightsquigarrow L(\tau) = \{n + m\tau \mid n, m \in \mathbb{Z}\} & \rightsquigarrow & T_\tau = \mathbb{C}/L(\tau) \\ \mathbb{C} & & \\ \pi_\tau \downarrow & & \\ T_\tau = \mathbb{C}/L(\tau) & \xrightarrow{\varphi} & \mathbb{C} \end{array}$$

So, very very quickly let me say that you know; I have the upper half plane and there is a quotient of the upper half plane by the unimodular group $\text{PSL } 2 \text{ C}$ and we have seen that this is a Riemann surface and our aim is to show that this is a that this is isomorphic to the complex numbers as Riemann surface ok.

And I told you that in general if you want to even give a holomorphic function from this in to \mathbb{C} or for that matter if you want any function even said theoretic function from this into any set it is it is necessarily a function which is constant on orbits and you know the orbits correspond to holomorphic isomorphism classes of complex one dimensional Tori and therefore, you are trying to find a quantity which depends only on the holomorphic isomorphism class of a torus and in it is.

So, it is. So, the point is that looking at a function on this is essentially trying to find the invariants for tori. So, therefore, the point is. So, what are the Tori? I am talking about the Tori I am talking about are well if you take if you take a point τ in the upper half plane then you have the corresponding lattice τ give gives rise to this lattice $L \tau$ which is the all the complex numbers of form n plus $m \tau$ where n and m are integers and then you can take the complex plane and divide by this lattice to obtain a complex one dimensional torus ok

So, this gives rise to $t \tau$ which is $\mathbb{C} \text{ mod } L$ of τ and of course, you know that $t \tau$ is a complex one dimensional torus and this the canonical map by τ from \mathbb{C} to $\mathbb{C} \text{ mod } L$

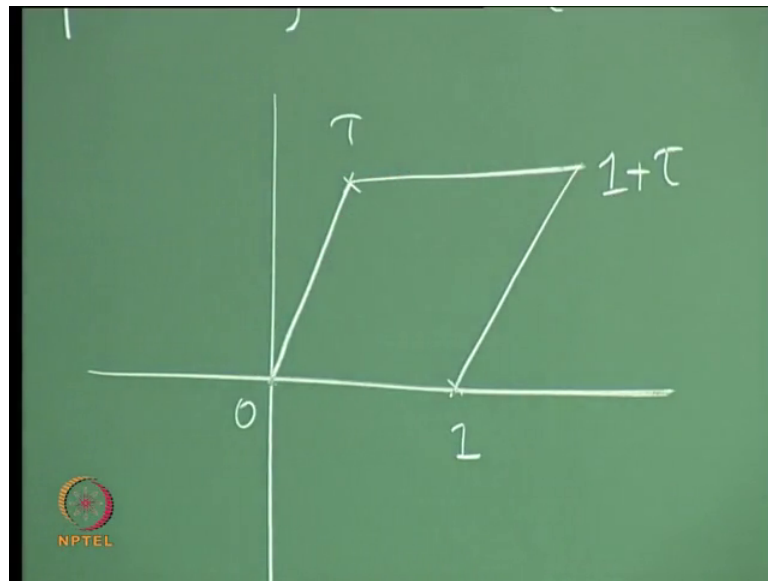

L of τ which is t sub τ this is a nice it is a universal covering map and the fundamental group of the topological space centre the torus can be identified with the deck transformation group of this cover which is which is which can be identified with the L τ which is considered as a subgroup of the holomorphic automorphism of C thought of as every element in L τ acting as a translation on c .

So, so essentially I am trying to look at I am trying to produce for each τ I am trying to produce something geometric that depends only on the holomorphic isomorphism class of this torus. So, I am trying to look for an invariant and as I was telling you by the philosophy explain the geometry of space should be controlled by the functions on this space therefore, I am tempted to look at functions on this and I told you that there is no use of looking at you know if I try to think of a holomorphic function. So, do not confuse this f with this f or maybe I will even put a ϕ , all right.

So, if I try to look for holomorphic functions on the torus that is of no use that is because if I compose this map I will get a holomorphic map I will get an entire function because after all this map is automatically holomorphic the way we have constructed it the Riemann surface structure on this is such that this map automatically becomes holomorphic. In fact, you know it is a local locally biholomorphic map because it is a holomorphic universal covering.

So, these are holomorphic map and if this is also holomorphic map the composite is also holomorphic map therefore, you get an entire function on C and then, but then you see this entire function on the other hand if you take the image of the function that is the same as the image of this, but this is a compact set this is compact and this is compact because it is the image of the period parallelogram formed by 1 n τ as the vectors 1 n τ as coterminous edges.

(Refer Slide Time: 06:41)

So, the picture is. So, I have; so, here is my. So, here is one and then here is my tau and then I have this fundamental. So, called fundamental parallelogram which corresponds to these 4 vertices which has these 4 vertices and of course, these 4 are the are elements here in this lattice and if I repeat this parallelogram on the whole plane, I will get the vertices will give me all the points in this lattice and the image of this closed parallelogram that is the interior along with the boundary is going to be the image of this function because after all it is periodic.

(Refer Slide Time: 07:28)

So, the point is that you will if I have a function here, then I get a function there suppose I call it as $\hat{\phi}$ then $\hat{\phi}$ of course. So, I put this circle or arrow to say that this function is just this forward by this and $\hat{\phi}$ of course, has to be periodic with periods one and τ which is the same as which means that $\hat{\phi}(Z + n + m\tau)$ should be the same as $\hat{\phi}(Z)$ for all Z and for all n, m integers ok.

This is dictated by the fact that I mean this is this is just because $\hat{\phi}$ goes down to a function a function above can go down to a function below if and only if it is periodic with respect to this parallel with respect to this lattice that is if the function values are the same if you translate by an element of this lattice. So, such functions. So, you can see for such a function one is a period because $\hat{\phi}(Z + 1)$ is $\hat{\phi}(Z)$ and $\hat{\phi}(Z + \tau)$ is also $\hat{\phi}(Z)$. So, 1 and τ are periods. So, these are called W periodic functions and the other name for that are elliptic functions. So, these are elliptic functions, but trying to require that ϕ is holomorphic is of no use because then the image of ϕ is the same as the image of $\hat{\phi}$ of this closed parallelogram; that is being clear along with the edges ok.

But then that is a compact set because it is closed and bounded and that and $\hat{\phi}$ being $\hat{\phi}$ and ϕ being continuous the image will be a compact subset of X . So, it will be bounded. So, I will have a bounded holomorphic bounded entire function and by (Refer Time: 09:24) theorem, it has to be a constant therefore, it will not help if I am try to look for holomorphic functions on the complex one dimensional torus I have I am forced to look at their 4 functions with singularities and of course, the main the singularities one can think of are singularities which are poles.

So, I can think of functions which have isolated poles as the only singularities and such functions are called as meromorphic functions and the simplest case is that I can think of a function with a single with a pole at only 1 point and then I have explained to you in the last lecture that if you are going to work with a function which has a pole at only one point then that pole cannot be a simple pole it has to be at least a double pole and then we try to place. So, if the if this function has a pole at the point which is the image of this these lattice mind you all the points in this lattice go to a single point on the complex torus because they are all in the same orbit of this action by this group of translations.

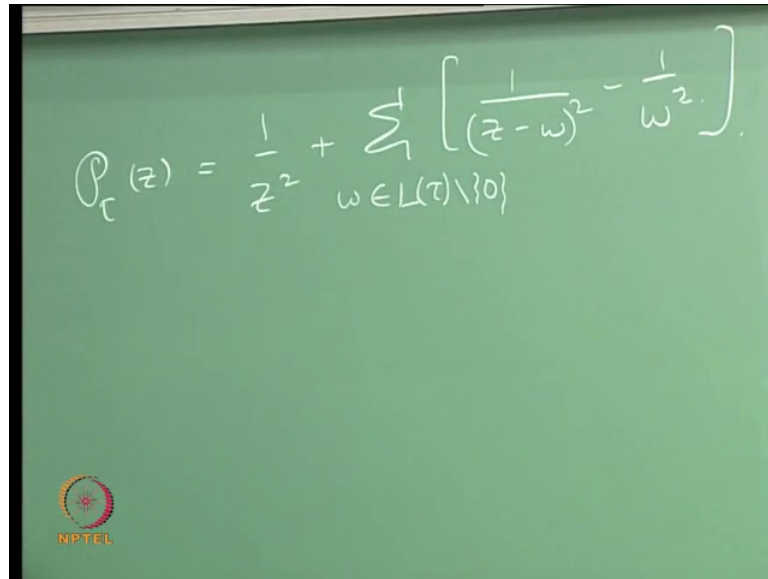

So, if you have a function which has a pole at any one of these points of order 2 that is the same as having a pole of order 2 at the origin all right and. So, you know. So, let me let me rewrite this diagram in the sense that I do not of course, I do not want ϕ to be holomorphic, I want ϕ to be meromorphic. So, I will put $\mathbb{C} \cup \infty$ and I will and then I will write holomorphic and this means that you know a holomorphic map into $\mathbb{C} \cup \infty$ is of course, a meromorphic function and the inverse image of infinity are the points that correspond to poles.

So, you see, we wanted a function which had a pole at each point of this lattice and the pole has to be a double pole therefore, you know we could up we were able to guess that roughly well if you want your pole at the point $n + m\tau$ of the lattice then this it should be one simple function that I can write down is of this form $(n + m\tau)^{-2}$ this is the pole of order 2 at $n + m\tau$ and then, but then because of periodicity this should happen if it happens at one point of the lattice, it should happen at every point of the lattice.

So, I will have to take the summation of this over n, m bearing over integers bearing over integers all right. So, I get this I get this family of I get this. So, double series. So, to say of meromorphic functions each terms is in fact, a rational function and then I have this series all right and the fact is that we are we are; so, this can also be written as you know you can also write it as $\sum_{n, m} \frac{1}{(n + m\tau)^2}$ you can write it like this I can write it like this and, but this as I will show very soon this is not; this will not give you as it is it will not give you convergence because whenever you write something like this you write a series of meromorphic functions you have to be you have to put some condition.

So, that this series converges at least at the points where there are no poles because where there are no poles you want it to be an analytic function. So, meromorphic function is analytic except for poles all right and the poles have to be isolated in this case anyway the grid points the points of this lattice are of course, isolated.

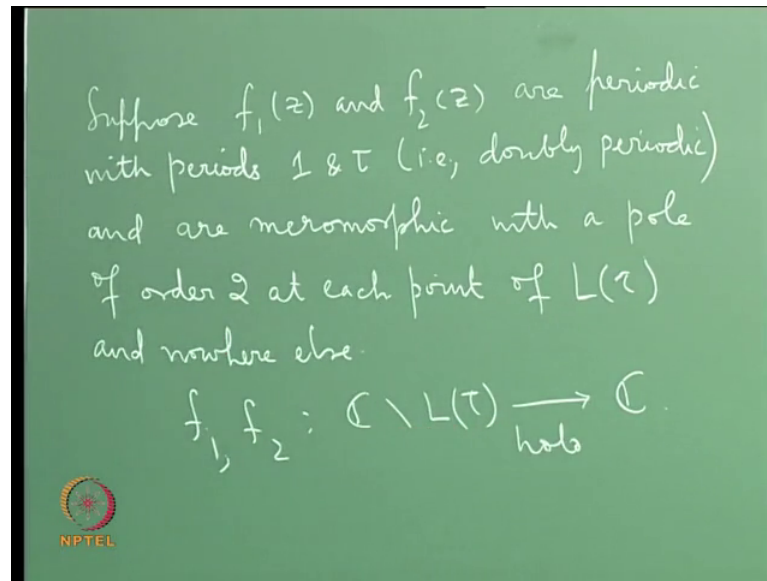

(Refer Slide Time: 14:11)

$$P_c(z) = \frac{1}{z^2} + \sum_{\omega \in L(\tau) \setminus \{0\}} \left[\frac{1}{(z-\omega)^2} - \frac{1}{\omega^2} \right]$$

So, to avoid convergence problems what one does is one defines the Weierstrass phi function in the following way one defines a phi function associated to this; this tau in the upper half plane. So, this associated to this torus as 1 by x squared plus sigma omega a non-zero element of the lattice 1 by 2 Z minus omega the whole squared minus 1 by omega squared. So, this is this is the expression the fact is that you know if you forget this minus 1 by omega squared here, then whatever I have written is exactly what is here they only thing is extra 1 by omega squared is added I have put this one by I have taken out this one by Z squared because you know if I include origin then I cannot put one by 0 squared it does not make sense. So, I had to pull out this Z squared out and then I have taken out this contribution as Z tends to omega this term becomes one by omega squared and I have subtracted that here.

But of course, as Z tends to omega this is going to go to infinity because it is a pole of order two, but the fact is you will see you will see very soon that this is very important to make sure that this converges at all points outside the lattice we will prove that. So, this is the Weierstrass phi function and this dictates the point is this is essentially the important meromorphic function on this torus and it dictates the geometry of the torus all right it. So, we will see; how it how that is true in the in this and the following lectures so, but before that I will have to justify that all this is proper I mean well defined and so on and so forth.

(Refer Slide Time: 16:05)

So, let me make a; let me start with a few remarks the first thing is; so, suppose suppose f_1 ; let me say f_1 of Z and f_2 of Z suppose I take 2 functions are periodic W periodic or let me say periodic with periods one and τ that is W periodic and let me say that and are and are meromorphic with a pole of order 2 at each point of the lattice and nowhere else ok.

So, you see, I am looking at 2 function, I am looking at 2 metamorphic functions on the complex plane. So, these so; that means, you know f_1 f_2 are defined from \mathbb{C} minus the lattice to \mathbb{C} and they are holomorphic, but for the points on the lattice and at each point of the lattice they have a pole of order 2 now. So, so you see what I want to say is that f_1 such functions can be normalized in a certain way.

So, that you finally, end up getting only one unique function and that unique function has to be the Weierstrass ϕ function that is called the Weierstrass ϕ function by uniqueness and that function is this one has a formula like this. So, what is that normalization? So, the normalization is well we will let me thing for a movement. So, you see f in particular you know if you the normalization is defined by looking at the Laurent expansion or the function in a neighborhood in a deleted neighborhood of the origin see the origin is of course, a point of the lattice and the function has a pole of order 2 at the origin all right and if you write out the Laurent expansion at the origin you see; it will be in the form in the following form.

(Refer Slide Time: 19:21)

and nowhere else

$$f_1, f_2 : \mathbb{C} \setminus L(\tau) \xrightarrow{\text{hole}} \mathbb{C}$$

In a deleted neighbourhood of 0,
the Laurent developments look like

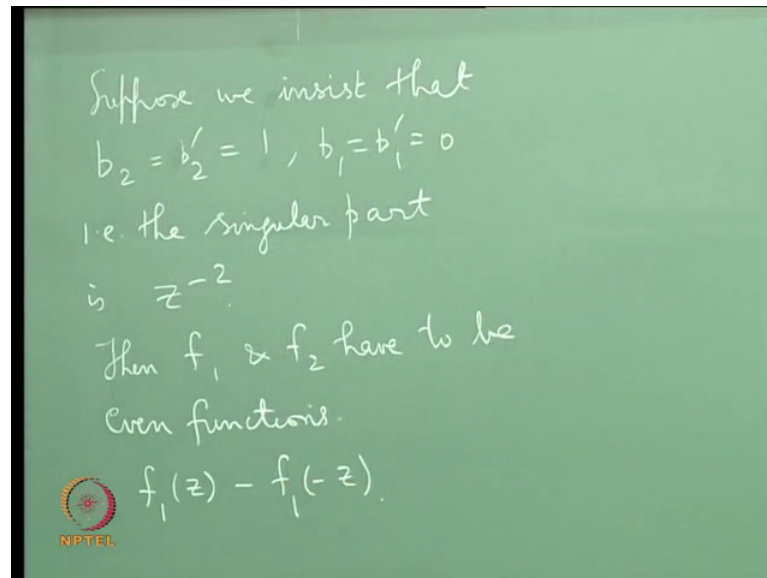

$$f_1(z) = \frac{b_2}{z^2} + \frac{b_1}{z} + a_0 + a_1 z + a_2 z^2 + \dots$$

$$f_2(z) = \frac{b'_2}{z^2} + \frac{b'_1}{z} + a'_0 + a'_1 z + a'_2 z^2 + \dots$$

So, let me try that out in a day in a deleted neighborhood of 0 the Laurent; the Laurent developments the Laurent developments are look or let me say in they are; they look like look like f_1 of Z , it is going to be you see it is a pole of order 2. So, what I will get is I will get b_2 by Z squared Z equal to zeroes of pole of order 2. So, I will get b_2 by Z squared plus b_1 by Z plus b naught plus let me say a naught plus $a_1 Z$ plus $a_2 Z$ squared and. So, on and if I take f_2 well I will have to use. So, . So, I will put primes I will say b_2 prime by Z squared plus b_1 prime by Z plus a naught prime plus a_1 prime Z plus a_2 prime Z squared and so on.

The Laurent development is going to look like this that is because Z equal to 0 is a, this is a Laurent development about centered at the origin and the origin is not included. So, it is a punctured neighborhood of the origin and this is the Laurent series development for these 2 functions and the point is that these 2. So, this part this corresponds to the so called singular part of the Laurent development the rest of it is an analytic function the rest of it is an analytic function. So, now, the normalization condition that I put is I will set the coefficient of one by Z squared to be one that is a normalization condition I put.

(Refer Slide Time: 21:27)

So, suppose we put we insist that $b_2 = b'_2 = 1$ suppose if we insist this. So, this is the first normalization condition that is you take the elliptic function all right and look at the Laurent development at the origin and insist that the singular part contains only Z to the minus 2 with a coefficient one and the in particular it means I am setting b_1 and b_1 prime to be 0.

So, let me write that $b_1 = b_1$ prime is equal to 0 that is in other words, the condition is the singular part a singular part is Z to the minus 2 that is a singular part in general, the singular part will be some it will be some constant into Z to the minus 2 plus some constant Z to the minus 1 the normalization that I do is that I say the singular part has to be Z to the minus 2. Now the claim is that once you do this then any such function automatically becomes an even function. So, that is a first observation all right. So, then f_1 and f_2 have to be even functions f_1 and f_2 have to be even functions see for why see for example, see you look at you look at f_1 of Z minus f_1 of minus Z ; look at this function look at the function $f_1 Z$ minus f_1 of minus Z .

(Refer Slide Time: 23:32)

Then f_1 & f_2 have to be even functions.

$$\begin{aligned} f_1(z) - f_1(-z) &= \left(\frac{1}{z^2} + a_0 + a_1 z + a_2 z^2 + \dots \right) \\ &\quad - \left(\frac{1}{z^2} + a_0 - a_1 z + a_2 z^2 - \dots \right) \\ &= 2a_1 z + 2a_3 z^3 + \dots \end{aligned}$$

NPTEL

Then you see, you will see that if I explained it what I will get is I will get you see I will get a 1 a 1. So, let me write it down.

So, $f_1(z)$ is going to be well $\frac{1}{z^2}$ plus a naught plus a $1z$ plus a $2z^2$ plus so on minus $f_1(-z)$ is going to be $\frac{1}{z^2}$ plus a naught minus a $1z$ plus a $2z^2$ minus and so on. So, what I am going to get is I am going to get the point is you see the in a in the neighborhood of the origin the only pole that I have that is removed. So, what happens is I simply get I simply get $2a_1 z$ plus $2a_3 z^3$ and so on and what is this notice that this is a this is an analytic function that the difference is an entire function it is an analytic function and see whatever I have done. So, I am looking at the origin I am looking only at the origin that the if you look at the difference the difference in a entire function, but on the other hand notice that both of them still have the same periods one and τ .

If I change EZ to $EZ + n + m\tau$ and here also if I change minus EZ to minus $EZ + n + m\tau$ because f_1 has $n + m\tau$ as periods one and τ as periods it is still W periodic. So, what is this computation tells you is it you are having a W periodic function which is on a which is which is entire I mean which is which is which has no poles. So, see the point is that this difference is W periodic function it has no pole at the origin therefore, it has no pole at any other lattice point the difference function has no pole at any other lattice point because after all the values of the function are the same if

you displace by an element of the lattice translate by an element of the lattice. So, therefore, this difference becomes an entire function all right which is W periodic and it has to be a constant again by (Refer Time: 26:07) theorem.

(Refer Slide Time: 26:10)

is z .

Then f_1 & f_2 have to be even functions.

$$f_1(z) - f_1(-z)$$

$$= (a_0 + a_1z + a_2z^2 + \dots) - \left(\frac{1}{z^2} + a_0 - a_1z + a_2z^2 - \dots\right)$$

$$= 2a_1z + 2a_3z^3 + \dots$$

$$= \text{entire \& bounded}$$

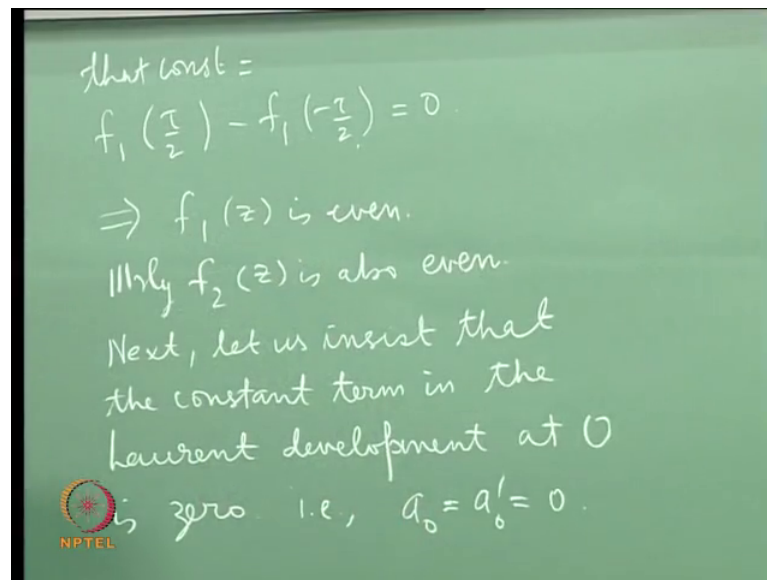

$$= \text{const.}$$

NPTEL

Therefore, this is equal to this; this is entire and bounded; the boundedness comes from the W periodic nature.

So, this will be equal to a constant. So, this difference has to be a constant and the claim is that that constant is actually 0 that constant is actually 0 because if you want you know I can put half put Z equal to half or put Z equal to tau by 2 put something either half or tau by 2.

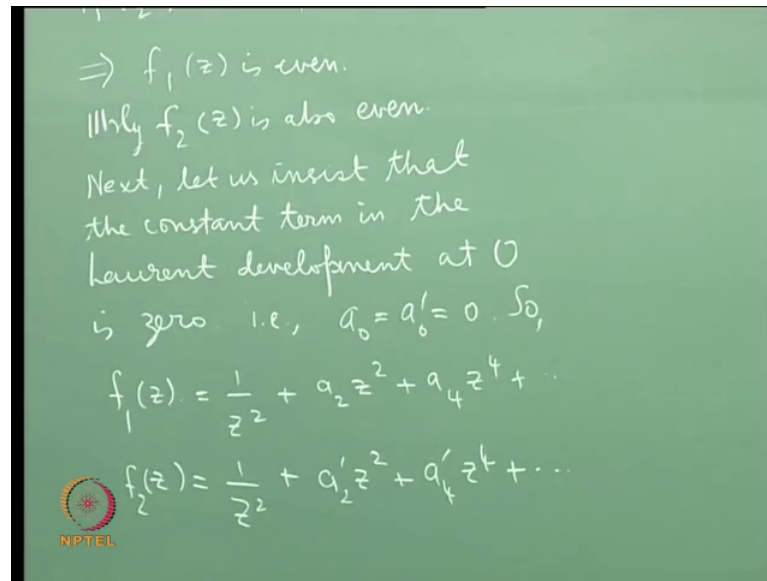

(Refer Slide Time: 26:44)

So, you know I will get f_1 of let us say τ by 2 minus f_1 of minus τ by 2 that constant is also going to be equal to this and this is going to be 0 this going to be 0 because the difference between these 2 Z values is τ and τ is a period and the function does not change its value if you change the argument by translate the argument by a period. So, the constant is 0 as a result what this argument tells you is that f_1 of Z is even f_1 of Z is even.

So, the point is the moment you put the condition that the singular part is Z to the minus 2 the function becomes even the function becomes even. So, now, I am going to put one more condition for the normalization and that that condition is going to be that when you write out this Laurent expansion I am going to insist that the constant term is 0 I am going to insist the second condition I am going to put is that the constant term is 0 suppose. So, let me write this here similarly f_2 of Z is also even for the same reasons now next let us insist that let us insist that the constant term in the Laurent development in the Laurent development at the origin is 0, let us put this extra condition. So, that means. So, in this discussion I am saying put a_0 equal to 0 a_0' equal to 0 ok.

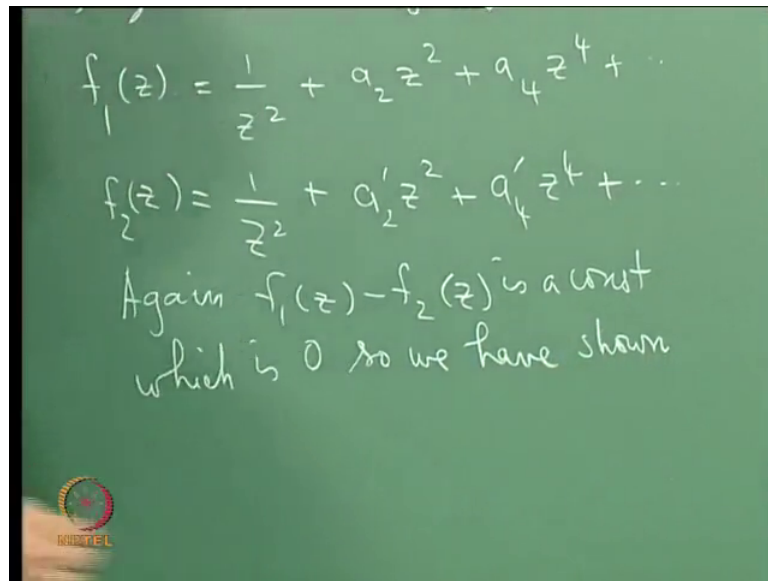

(Refer Slide Time: 28:55)

So, you see what will happen is that f_1 of z will now have this expansion, it will be one by Z squared plus a 2 8 squared plus a 4 Z power 4 and so on mind you, it is an even function. So, you have the expansion has to be like this and f_2 of Z will be again one by Z squared plus a 2 prime Z squared plus a 4 prime Z power 4 and so on. So, this how the Laurent expansions are going to look like now you see again if I subtract the 2 again if I subtract the 2, I will get an entire function which is W periodic and therefore, it will be a constant and therefore, these 2 have to be equal.

So, the upshot of the story is you take a W periodic function you that is an elliptic function with exactly a pole of order 2 at each point of the lattice you put these 2 normalization conditions namely in the Laurent expansion at the origin the singular part is 1 by Z squared and the second condition is that the constant term is 0, then there is only 1 function and the claim is that one function is the Weierstrass ϕ function and the function is given by this formula that is the claim.

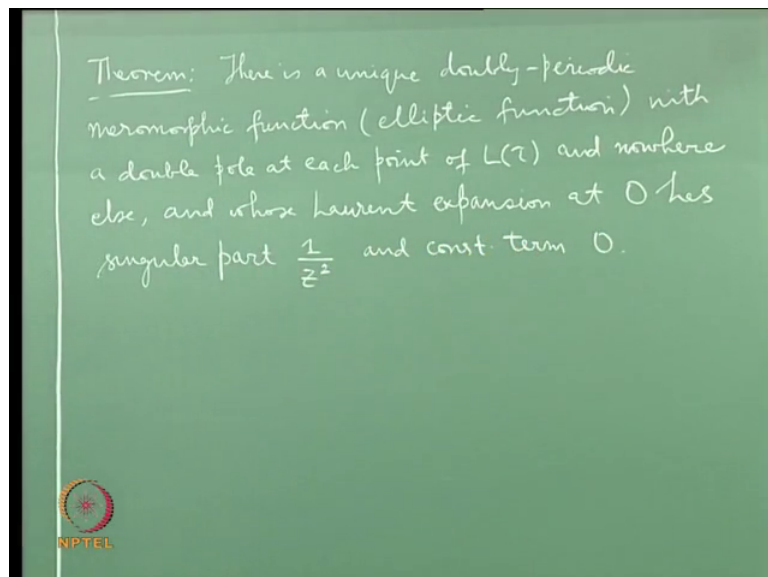

(Refer Slide Time: 30:32)

$$f_1(z) = \frac{1}{z^2} + a_2 z^2 + a_4 z^4 + \dots$$
$$f_2(z) = \frac{1}{z^2} + a'_2 z^2 + a'_4 z^4 + \dots$$

Again $f_1(z) - f_2(z)$ is a const
which is 0 so we have shown

So, let me write that down again, f_1 of Z minus f_2 of Z is a constant which is 0 which is 0. So, so we have we have we have shown. So, what we have shown is the following. So, I can write it here. So, maybe I will draw some lines here. So, that. So, what we have shown is the following theorem.

(Refer Slide Time: 31:15)

Theorem: There is a unique doubly-periodic meromorphic function (elliptic function) with a double pole at each point of $L(\tau)$ and nowhere else, and whose Laurent expansion at 0 has singular part $\frac{1}{z^2}$ and const. term 0.

There is a unique W periodic meromorphic function elliptic function with a double pole at each point of L of τ and nowhere else and whose Laurent expansion at the origin has singular part 1 by Z squared and constant term zero. So, what I proved is that there is

essentially only one I mean I had given these normalization exactly one W periodic meromorphic function with pole of order 2 at each lattice point and with the extra normalization condition that the Laurent expansion at 0 that is at the singular part is one by Z squared and the constant term is 0. So, this is what this is what the discussion shows.

Now, what I am going to do is I am going to show tell you I am going to call that function as the Weierstrass ϕ function that is it that unique function I am going to call it the Weierstrass ϕ function associated with the torus. So, let me write that we call this unique function ϕ of Z and the Weierstrass ϕ function associated to τ or τ or $L\tau$ or 2τ in the upper half plane. So, this is the; we call this unique function as a Weierstrass ϕ function.

So, you must all be wondering that I have written this thing here. So, that is going to be the next thing that we are going to show I am going to show that the right side has all these properties I am going to show that the right side is a meromorphic function it is W periodic of course, the Laurent expansion at the origin the singular part is exactly one by Z squared and that constant term is 0, therefore, this has to be equal to that is what I am going to do next ok.

So, and that will tell you that this is indeed the expression for the Weierstrass ϕ function.

(Refer Slide Time: 34:57)

Handwritten text on a green chalkboard:

We next show that the series

$$S(z) = \frac{1}{z^2} + \sum_{w \in L \setminus \{0\}} \left[\frac{1}{(z-w)^2} - \frac{1}{w^2} \right]$$

is $\phi_T(z)$.

NPTEL logo is visible in the bottom left corner of the chalkboard image.

So, let us do that we next show that the series. So, let me let me give it a name phi of Z let me call it as phi of Z let me call it phi of z, but I do not want you to confuse that phi with phi hat. So, let me call this something let me call it as f of Z. So, suppose I call this or maybe even S of Z if it helps. So, S of Z is that series $1 + \sum_{\omega \in \Lambda} \left(\frac{1}{\omega^2} - \frac{1}{(\omega + \tau)^2} \right)$ in the lattice $\omega \neq 0$ lattice $\omega \neq 0$ of this expression which is $1 + \sum_{\omega \in \Lambda} \left(\frac{1}{\omega^2} - \frac{1}{(\omega + \tau)^2} \right)$ we next how that the series this series has all these properties and. So, has to be equal to the Weierstrass phi function is phi is a Weierstrass phi function we show this ok.

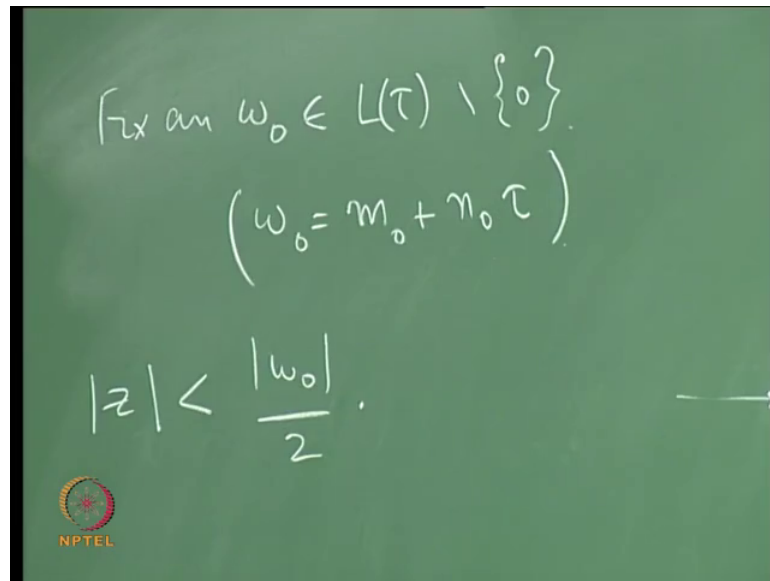

So, let me do that. So, so the first thing that I need to worry about is the convergence the first thing that I need to worry about is the convergence.

(Refer Slide Time: 36:54)

So, you see let me let me draw a diagram. So, picturing the lattice; so, I have. So, this is my tau this is one let me put it here one point. So, this is my. So, and this is one plus tau. So, I have this I have this lattice; this lattice of points repeating themselves.

(Refer Slide Time: 37:34)

$$\text{Fix an } \omega_0 \in L(\tau) \setminus \{0\}$$
$$(\omega_0 = m_0 + n_0 \tau)$$
$$|z| < \frac{|\omega_0|}{2}$$

So, I will have 2 and so on and so forth and so, you see fix and omega not in the lattice you fix and omega are not I the lattice which is not which is non zero. So, you see this omega naught is going to be therefore, of the form m naught plus n naught tau where both m naught and n naught are not simultaneously 0 and let us look at the condition $\text{mod } Z$ lesser than $\text{mod of } \omega_0$ naught by 2 I am going to look at this condition, I am going to look at this open disk.

So, you see well omega naught is for example, some point of the lattice and you know I am, then this is the vector that represents omega naught and the length of this vector is $\text{mod } \omega_0$ naught and I am looking at. So, $\text{mod } \omega_0$ naught by 2 is going to be something here and therefore, I am looking at this disk. So, this is the radius of; this is $\text{mod } \omega_0$ naught by 2 and I am looking at all the all the complex numbers Z here and of course, and I am trying to estimate each term of that series I am. In fact, in particular I would like to estimate the term of this series that corresponds to omega equal to omega naught right. So, let us do that see what is the term inside.

(Refer Slide Time: 39:27)

$$\left| \frac{1}{(z - \omega_0)^2} - \frac{1}{\omega_0^2} \right| = \left| \frac{\omega_0^2 - (z - \omega_0)^2}{\omega_0^2 (z - \omega_0)^2} \right|$$

$$= \left| \frac{(\omega_0 - z + \omega_0)(\omega_0 + z - \omega_0)}{\omega_0^2 (z - \omega_0)^2} \right| = \left| \frac{z(2\omega_0 - z)}{\omega_0^2 (z - \omega_0)^2} \right|$$

$$\leq \frac{|z|(2|\omega_0| + \frac{|\omega_0|}{2})}{|\omega_0|^2 \frac{|\omega_0|^2}{4}} = \frac{10|z|}{|\omega_0|^3}$$

It is $\frac{1}{(z - \omega_0)^2} - \frac{1}{\omega_0^2}$ the whole square minus $\frac{1}{\omega_0^2}$ squared this what I have and if I take the mod of this what do I get I get well it will be ω_0^2 squared minus Z minus ω_0 squared by ω_0^2 squared into Z minus ω_0 squared whole squared mod and this will be 12 this is well two. So, it is $\omega_0 - z + \omega_0$ into $\omega_0 + z - \omega_0$ into this ω_0^2 squared into Z minus ω_0 squared and that turns out to be well I will get Z into $2\omega_0$ minus Z by ω_0^2 squared into Z minus ω_0 squared.

And if I estimate this see I will get this is less than or equal to you see of course, I can replace this Z by mod ω_0 by 2 in the numerator, but I do not do it purposely. So, I will get I will keep this mod Z as it is you will see why I am I why I am not doing it the reason for that. So, I am keeping this mod Z as it is all right and this $2\omega_0$ minus Z mod can be written by triangle inequality to be less than or equal to you know well 2 times mod ω_0 plus mod ω_0 by 2 , I can write this I am just using mod of a plus b is less than or equal to mod a plus mod b and I am using mod Z is less than mod ω_0 by 2 and of course, this ω_0^2 squared in the denominator I am I am not going to worry about it and this one this mod Z minus ω_0 is by triangle inequality it is greater than equal to modulus of mod Z minus mod ω_0 and that will give me. So, the reciprocal of that will be less than or equal

to the reciprocal of modulus of mod Z minus mod ω naught this is what I will get all right.

And yeah; so, I just wanted to say that. So, I just wanted to say that this can be. So, yeah this can be replaced by mod ω naught squared by 4 again by using finding inequality all right. So, yeah; so the upshot of all this is I will get well I will get $5 \cdot 10 \cdot 10$ mod Z by mod ω naught cube. So, I need this you see if I had replaced the mod Z by again by mod ω naught by 2 I will get only a mod ω naught squared and mind you your lattices in 2 dimensions it is not good to have one by mod ω naught mod ω squared and trying to sum it.

So, now what I want you notice is that if mod Z ; see if mod Z if see. So, what I am going to; let me say what I am going to write down if you take any points of the lattice which are outside; I am in which are outside the circle centered at the origin and radius mod ω naught, then it is also true that mod Z is also lesser than mod ω by 2 ok and the all these calculation will all the these estimation will be will hold with ω naught replaced by ω .

The point is it will hold for all ω that is out that are outside this that are outside this circle points of the lattice that are outside this circle and what is left out are only finitely many points which are inside the inside the circle. So, the convergence is essentially a question of whether for all points outside the series converges and what we will show is that the series is numerically dominated by some multiple of $\sum 1/n^2$ which you know it converges. So, and that is where we will use this you will need this ω naught for the cube.

So, let me explain that. So, and of course, in all these calculations; one is of course, assuming that when you sum it up you are assuming that Z is not going to be any one of the; of course, not going to be any one of the lattice points because if Z is any of that ω s in consideration then this term does not make sense because it becomes 0.

(Refer Slide Time: 45:25)

$$\text{For all } w \in L(\tau) \text{ with } |w| \geq |w_0|,$$
$$|z| < \frac{|w_0|}{2} \leq \frac{|w|}{2}, \text{ so}$$
$$\left| \frac{1}{(z-w)^2} - \frac{1}{w^2} \right| \leq \frac{10|z|}{|w|^3}.$$

So, you see for all ω in L off τ with $|\omega| \geq |\omega_0|$ greater than or equal to $|\omega_0|$ is fine.

You will similarly get that $|z|$ is going to be certainly less than $|\omega|$ by 2 this has to happen because $|z|$ is going to be less than or equal to $|\omega|$ by 2 and that is less than or equal to $|\omega|$ by 2. So, the same kind of calculation will tell you that $\left| \frac{1}{(z-w)^2} - \frac{1}{w^2} \right|$ is bounded by $\frac{10|z|}{|w|^3}$ all right. So, therefore, you see if I look at this series.

(Refer Slide Time: 46:20)

$$S_0 \sum_{\substack{\omega \in L(\tau) \\ |\omega| \geq |\omega_0|}} \left| \frac{1}{(z-\omega)^2} - \frac{1}{\omega^2} \right| \leq \sum_{\substack{\omega \in L(\tau) \\ |\omega| \geq |\omega_0|}} \frac{10|z|}{|\omega|^3}$$

Claim: Since τ is non-real, $\exists \lambda > 0$
 such that $|n+m\tau| \geq \lambda(|n|+|m|)$
 \forall pairs of real nos. (n, m)

I mean tail end of the series you take ω in L of τ you take all ω in L of τ with $\text{mod } \omega$ greater than or equal to $\text{mod } \omega_0$, then this series one by Z minus ω the whole squared minus 1 by ω squared if I look at this series this is just the that series except for finitely many terms.

So, that converges if and only if this converges all right. So, and if I look at the absolute series if I look at the absolute series what I will get is I will I will get that this is it is going to be by this estimate ω belonging to L of τ summation over $\text{mod } \omega$ greater than to $\text{mod } \omega_0$ and I will get $10 \text{mod } Z$ by $\text{mod } \omega$ the whole cube this is what I get now what I am going to say is that this is actually going to converge and for that there is there is little bit geometric in insight that is needed.

So, here is a claim since τ is non real, since τ is non real there exists a λ greater than 0 for a real λ greater than 0 such that such that modulus of n plus $m\tau$ is always greater than λ times greater than or equal to λ times $\text{mod } n$ plus $\text{mod } m$. So, you see this is something that you can immediately think of geometrically, but it is an exercise to verify that this holds roughly you know if I draw a diagram at least you should be able to see why this is a result that can be expected because you see and of course, here n and m need not necessarily be integers n and m could be any pairs of real numbers ok.

So, let me write that also for all pairs of real numbers n and m . So, I am saying real numbers. So, in particular, it will also hold for pairs of integers. So, what does this mean see if you if I draw this if I draw this lattice.

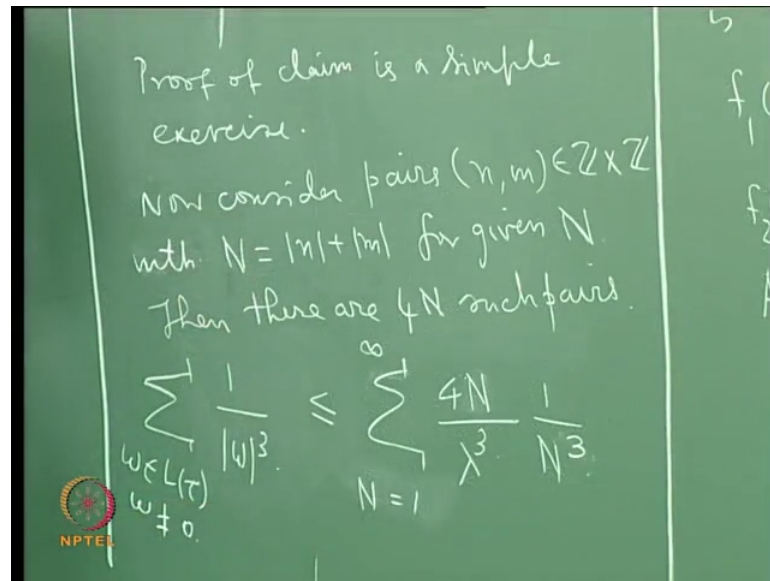

(Refer Slide Time: 49:17)

So if I draw this lattice. So, you see I have see let us assume that say n and m are positive. So, you see. So, this will be this point will be n times one and then I will have if this is a direction of if this is τ then I will have some something like this, this will be n plus $m \tau$ and you know if I and this is one of course, somewhere here I am assuming n is greater than one in this diagram. So, if I join this you see this length is modulus of n plus $m \tau$ and you see if I take modulus of n plus $m \tau$ and if I divide it by $|n| + |m|$ I am actually dividing by you know this length and by the factor of this length by τ and you can see that the ratio; it cannot go to it has to be bounded below $|n| + |m|$ by $|n| + |m|$ that ratio has to be bounded below by something positive it cannot go to 0 all right.

So, it is kind of geometrically very acceptable if you look at this picture, but but one needs to actually show that this is true because τ is i is in the upper half plane. So, it is it is a non real quantity. So, this is the small exercise which I will ask leave to you to do and lets believe this exercise then and then.

(Refer Slide Time: 51:16)

So, proof of claim is a simple exercise which I will ask you to do and, but let us apply it. So, you know if now consider now consider pairs n comma m which are integers and n is mod n plus mod m for given n . So, look at these quantities actually this the this there is a double summation here I mean I mean there are 2 there are 2 freely I mean there are 2 integers here, but I want to group it into one.

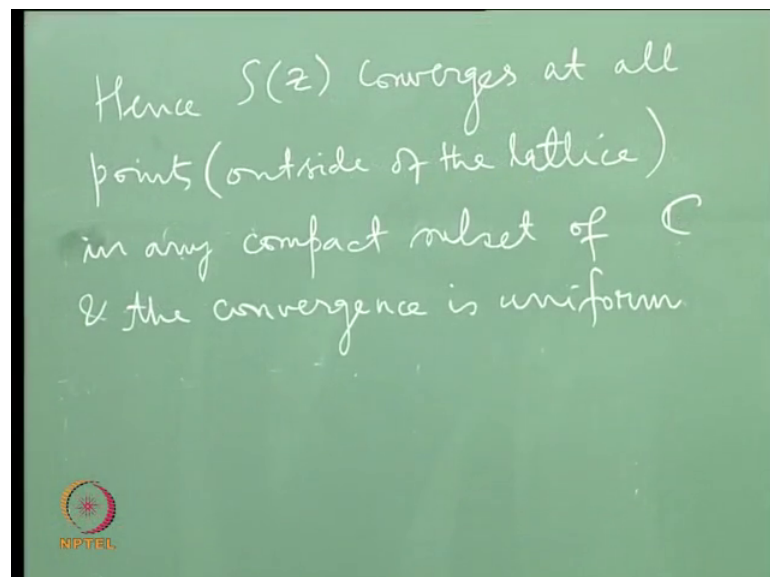

So, what I do is I look at all those pairs n comma m such that mod n plus mod m is accepting capital n then how many do I get I will get 4 capital n such pairs because you know for every pair n comma m the n comma minus m is also another pair and then minus n comma m is also another pair and then minus n comma minus m is another pair. So, you actually get 4 of them and therefore, there are total 4 n such pairs. So, I should say now consider pairs with this, then there are or well 4 n such pairs there are 4 n such pairs and therefore, you see there are 4 n such pairs. So, you see if you if you look at if you try to sum over. So, if you try to sum over one by mod ω cube if you try to you sum over one by mod ω cube were where ω is in there is varying in the lattice ω not equal to 0 then you see this is this is less than or equal to all right 4 4 by. So, so let me let write that down 6 sigma ω in L of τ .

So, now I will change it to a summation n equal to 1 to infinity, all right, I will get 4 n 4 by 4 by λ cube 4 n by λ cube no I will get 4 n 4 by λ cube into one by n cube into one by n square right because. In fact, I will get 4 n by λ cube into one

by n^3 this is what I will get and you see and then of course, this n cancels and. So, essentially what I get is I get I can I can pull the 4 by λ^3 out and I will get $\sum_{n=1}^{\infty} \frac{1}{n^2}$ which you know converges and mind you see, this n above cancels with an n below. So, it should have been n^3 here if it had been n^2 I will get summation $\frac{1}{n}$ and that is going to diverge and why did I get n^3 because if you go back I let this ω I let this Z on top remain as it ok.

If I had replaced this Z by ω , then I would have lost this power of 3 here and I would I got a power 2 and then when I came back here I would have I would have just shown that this is dominated by $\sum \frac{1}{n^2}$ that is not going to be of any use. So, it is very purpose full that this Z was left as it is all right. So, what does this calculation tell you this calculation tells you that the. So, this calculation tells you that the series given by S of Z this calculation tells you that this series given by S of Z converges uniformly and absolutely on all compact sets and of course, at of course, you should not look at it at you are not worry, I mean you are not looking at the points which are poles namely the lattice points outside the lattice points this series converges.

(Refer Slide Time: 57:02)

So, hence S of Z converges at all points outside of the lattice in any compact subset of \mathbb{C} and the convergence is uniform.

Now, because of the uniformness the resulting function is also going to be analytic. So, you do get a function which is analytic accepted points of the lattice. So, then you have to worry about the at the points of the lattice you have to say that each point is a pole of order 2 you have to say that and then you have to say that there is this resulting function here you have to say that it is W periodic then you also have to then it will be more or less clear that because of this theorem because of this theorem it will be more or less clear it will be it will be clear that this is this has to be a Weierstrass phi function.

(Refer Slide Time: 52:42)

Thus $S(z)$ represents a meromorphic function with poles of order 2 exactly at points of $L(\tau)$

$$S'(z) = -\frac{2}{z^3} + \sum_{\substack{w \in L(\tau) \\ w \neq 0}} \frac{-2}{(z-w)^3}$$

$$= -2 \sum_{w \in L(\tau)} \frac{1}{(z-w)^3}$$

So, let us do that thus S of Z represents meromorphic function with poles of order 2 exactly at points of L of τ because you see if you look at points of L of τ see the same calculation will tell you that you know as Z goes close to ω you can see that. So, long a Z is not ω this series of course, converges, but because of this term the limit Z tends to ω will become infinite.

So, it will certainly be a pole and if you if you take limit EZ tends to ω of EZ minus ω the whole squared into S of Z you will see that that will be a non 0 quantity therefore, Z equal to ω each point of the lattice will certainly be your pole of order two. So, so it is certainly a meromorphic function with pole of order 2 at each of those points now the next thing, I want to tell you is that this is in fact, W periodic. So, the trick is as follows see you calculate the derivative of S of Z because of uniform convergence you can do term wise differentiation. So, you do term wise differentiation

and what you get you will get minus 2 by Z cube plus summation over omega in the lattice omega not equal to 0 of, I will if I differentiate this I will get minus 2 by Z minus omega the whole cube and I can write this compactly as minus 2 sigma 1 by Z minus omega the whole cube well with omega in the lattice.

I can also include I can also includes Z equal to 0 there I in the original explanation I had to remove Z equal to 0 term because I had this one by omega squared, but here that is gone. So, what I get is S prime of Z is this and this term is because this is the summation over the whole lattice if you if you translate is it by a lattice element this sum is not going to change therefore, this is certainly W periodic this is certainly W periodic function. So, let me notice that.

(Refer Slide Time: 62:04)

S prime of Z is periodic is W periodic with period 1 and tau, it is certainly W periodic with periods one and tau that is because you take an element of the lattice and if you translate the lattice by an element of the lattice they are going to get back the lattice. So, nothing is going to happen.

So, what is the upshot of this; if I take S of Z plus. So, suppose I take S of Z plus 1 minus S of Z suppose, I consider this difference S of Z plus 1 minus S of Z then and suppose I differentiate it, I will end up getting d by d Z of this will be 0 because I will get S dash of Z plus 1 minus S dash of Z, but S dash is P has period 1 and tau. So, this will be 0. So, what this will tell you is that you know S of Z plus 1 is equal to S of Z I mean minus S of

Z is a constant and that constant has to be 0. Now that constant has to be equal to S of minus half plus 1 minus S of minus half which is S of half minus S of minus half and this has to be 0 because if you look at the expression for S from the expression for S its very clear that S is an even function wherever it is defined.

So, what we have proved is that S of Z has 1 as a period the same kind of argument will show you that S has also τ as a period because d by dZ of S of Z plus τ minus S of Z will be 0 and that will imply that S of Z plus τ minus S of Z is a constant and now I can plug in minus τ by 2 and. So, that constant has to be S of minus τ by 2 plus τ minus S of minus τ by 2 and this is S of τ by 2 minus S of minus τ by 2 and that is again 0 as S is even. So, let me write it here also as S is even S is even because of its definition mind you we have not yet proved that S is W periodic. So, you have to be careful here ok.

So, what we have proved is therefore, S is W periodic and it is a meromorphic function with poles exactly at exactly at the points of the lattice pole of order 2 and if you look at the expression for S its clear that the singular part at the origin is one by Z squared.

(Refer Slide Time: 65:52)

The image shows a green chalkboard with handwritten mathematical derivations. The main derivation starts with the derivative of $S(z+\tau) - S(z)$ with respect to z being zero, which implies that $S(z+\tau) - S(z)$ is a constant. This constant is then evaluated at $z = \tau/2$ and $z = -\tau/2$, showing it is zero because S is an even function. The final result is the series expansion of $S(z)$ as $1/z^2 + \sum_{w \in L(\tau), w \neq 0} [\frac{1}{(z-w)^2} - \frac{1}{w^2}]$, which is identified as $P_\tau(z)$. The derivative $P'_\tau(z)$ is also given as $-2 \sum_{w \in L(\tau)} \frac{1}{(z-w)^3}$. A small NPTEL logo is visible in the bottom left corner of the chalkboard.

So, so let me write that down S of Z dash S of Z is 1 by Z squared plus sigma omega in the lattice omega not equal to 0 one by Z minus omega the whole squared minus 1 by omega squared is . So, let me say it in words it is the; it is W periodic with periods one and τ it has a pole of order 2 at each of the lattice points and if you look at the origin

you can see that this is going to be analytic in a neighborhood of the origin and the singular part is one by Z squared and it is also clear that the constant term in the Laurent development at the origin is 0, therefore, it satisfies all the conditions of the theorem that I stated and therefore, this has to be the Weierstrass ϕ function. So, is it $P(\tau)$ ok.

So, the upshot of all these is that you also have a nice formula for the derivative of the Weierstrass ϕ function which is going to be very important for us in the forthcoming lectures because that is going to tell you why the this why any complex torus is actually algebraic it is going to help us to explain that. So, let me also write that down the derivative is just minus $2\sigma\omega$ belonging to L of τ 1 by Z minus ω whole cube. So, I will stop here.
