The Gram-Schmidt Procedure 2

Ok so this is Gram-Schmidt Procedure the formula that I have written down. The idea is to construct an orthonormal set from a linearly independent set ok, this can also be used this procedure can also be used to determine if the set that we started with is linearly dependent ok this can also be used to determine if this $U_1 U_2$ etc is a linearly dependent set. Let me explain that.

(Refer Slide Time: 00:49)

Suppose this set is linearly dependent ok, then we have learnt that there is atleast one vector which can be written as a linear combination of the preceding vectors ok.

So I will say that there exists ofcourse I am assuming that zero vector does not belong to this, if zero vector is already there you don't have to check linear dependence ok. So I will assume that these are non-zero vectors and I want to see when it follows from the procedure that this set is linearly dependent. So there exists U let us say $m + 1$ such that there is atleast one vector that can be written as a linear combination of the preceding vectors.

(Refer Slide Time: 01:56)

$$u^{m+1} = \gamma_1 u^1 + \gamma_2 u^2 + \dots + \gamma_m u^m$$
$$\in \text{span}(\{u^1, u^2, \dots, u^m\})$$
$$\subseteq \text{span}(\{v^1, v^2, \dots, v^m\})$$
$$\text{So } u^{m+1} = \langle u^{m+1}, v^1 \rangle v^1 + \langle u^{m+1}, v^2 \rangle v^2 + \dots + \langle u^{m+1}, v^m \rangle v^m$$

NPTEL

So u^{m+1} such that u^{m+1} can be written as let us say $\gamma_1 u^1$ plus $\gamma_2 u^2$ etc $\gamma_m u^m$.

Now this belongs to span of u^1, u^2 etc of course which in turn is equal to contained in span of v^1, v^2 etc but what is extra about this v^1, v^2 etc, is that there are orthonormal vectors ok. So when I write u^{m+1} belongs to this span this vectors are orthonormal then we have this yesterday u^{m+1} can be written as scalar times v^1 plus scalar times v^2 etc, what are the scalars? Inner product of u^{m+1} with each of this, so that is $\langle u^{m+1}, v^1 \rangle$ this is $\langle u^{m+1}, v^1 \rangle v^1$ plus etc $\langle u^{m+1}, v^m \rangle v^m$ this is the expression for u^{m+1} in terms of the orthonormal vectors v^1, v^2 etc v^m ok.

(Refer Slide Time: 03:51)

Suppose that $\{u^1, u^2, \dots\}$ is linearly dependent.
 There exists u^{m+1} such that
 set $u^{m+1} = \alpha_1 u^1 + \alpha_2 u^2 + \dots + \alpha_m u^m$
 $\in \text{Span}(\{u^1, u^2, \dots, u^m\})$
 $\subseteq \text{Span}(\{v^1, v^2, \dots, v^m\})$
 So $u^{m+1} = \langle u^{m+1}, v^1 \rangle v^1 + \langle u^{m+1}, v^2 \rangle v^2 + \dots + \langle u^{m+1}, v^m \rangle v^m$
 $= \sum_{j=1}^m \langle u^{m+1}, v^j \rangle v^j$
 So $w^{m+1} = 0$

This is summation j equals 1 to m u^{m+1} is fixed we have v_j times v_j u^{m+1} is equal to this from this can you see that w^{m+1} is 0 the expression for w^{m+1} is here. So what does this convey? It means that any stage if you get the zero vector then you have linear dependence w^{m+1} is the vector that we are determining at the $m+1$ stage, if that turns out to be the zero vector then the vectors that we started with must be linearly dependent.

In fact u^{m+1} is a linear combination of the preceding m vectors. See this whole thing can be traced back, w^{m+1} is 0 if and only if u^{m+1} is equal to this which will tell you that u^{m+1} is a linear combination of the preceding m vectors ok. So one can check linear independence also by using the Gram-Schmidt Procedure, is that clear? Ok let's now look at two examples numerical examples and see how this procedure gives us orthonormal vectors.

(Refer Slide Time: 05:22)

Lets look at the case of \mathbb{R}^3 , V is \mathbb{R}^3 with the usual inner product I take the following vectors U_1 is $1\ 0\ 1$, U_2 is $0\ 1\ 1$ and U_3 is $1\ 1\ 0$ ok then you can verify that these vectors are linearly independent, so they form a basis for \mathbb{R}^3 .

You would like to construct an orthonormal basis for \mathbb{R}^3 starting with this linearly independent set ok. So lets do the computation. The inner product is the usual inner product so the norm is the Euclidian norm. So if you look at norm of U_1 that is root 2 and the formula for V_1 is U_1 by norm U_1 which is 1 by root 2 into $1\ 0\ 1$, this is V_1 and it is clear that norm of V_1 is 1 , that is how it has been constructed.

(Refer Slide Time: 06:40)

$$\begin{aligned}W^2 &= U^2 - \langle U^2, V^1 \rangle V^1 \\&= (0, 1, 1) - \frac{1}{2}(1, 0, 1) = \left(-\frac{1}{2}, 1, \frac{1}{2}\right) \\&= \frac{1}{2}(-1, 2, 1) \\V^2 &= \frac{W^2}{\|W^2\|} = \frac{1}{\sqrt{3}} \left(\frac{1}{2}\right) (-1, 2, 1) = \frac{1}{\sqrt{6}}(-1, 2, 1)\end{aligned}$$

NPTEL

To construct a V_2 we must construct W_2 , W_2 is U_2 minus the inner product of U_2 with V_1 into V_1 from the formula so U_2 is $0 \ 1 \ 1$ minus inner product of U_2 with V_1 this two terms get cancelled you get $1, 1$ by root 2 minus 1 by root 2 into V_1 , V_1 again goes with a 1 by root 2 so I will write 1 by 2, V_1 goes with a 1 by root 2, $1 \ 0 \ 1$ so that is $\text{minus } 1 \text{ by } 2$ and 1 minus 1 by 2 let me write this as 1 by 2 outside minus $1 \ 2 \ 1$ that is W_2 this does not have norm 1 so I must divide define V_2 as W_2 by norm W_2 , norm W_2 is 1 by 4 into 1 plus 4 plus 1 that's 6 by 4 that's 3 by 2, 1 by that plus 2 by 3 into 1 by 2 I think root 2 by 3 into $\text{minus } 1 \ 2 \ 1$.

So let us compute this gets cancelled 1 by root 6 into $\text{minus } 1 \ 2 \ 1$, this is my V_2 , for one thing norm V_2 is $1, 1$ plus 4 plus 1 by 6 the W_2 must be orthogonal to V_1 which is clear this is $\text{minus } 1$ by 2 this a plus 1 by 2 the dot product is zero I am just checking the calculations. So this is V_2 .

(Refer Slide Time: 08:47)

$$\begin{aligned}
 w^3 &= u^3 - \langle u^3, v^1 \rangle v^1 - \langle u^3, v^2 \rangle v^2 \\
 &= (1, 1, 0) - \frac{1}{2}(1, 0, 1) - \frac{1}{6}(-1, 2, 1) \\
 &= \left(\frac{2}{3}, \frac{2}{3}, -\frac{2}{3}\right) = \frac{2}{3}(1, 1, -1) \\
 v^3 &= \frac{w^3}{\|w^3\|} = \frac{\sqrt{3}}{2} \cdot \frac{2}{3}(1, 1, -1) = \frac{1}{\sqrt{3}}(1, 1, -1)
 \end{aligned}$$

 NPTEL

v^3 is constructed using w^3 , w^3 is u^3 minus $u^3 \cdot v^1 \cdot v^1$ minus $u^3 \cdot v^2 \cdot v^2$, u^3 is 1 1 0 minus $u^3 \cdot v^1 \cdot v^1$ see this 1 by root 2 comes twice because v^1 comes twice so you go with 1 by 2. So I will write 1 by 2 first what is $u^3 \cdot v^1$? $u^3 \cdot v^1$ first just 1, so it is just 1 multiply by v^1 . So v^1 is 1 by 2 I have already written this 1 0 1 minus $u^3 \cdot v^2$ with $u^3 \cdot v^2$, v^2 goes with a 1 by root 6 so I get a 1 by 6 outside $u^3 \cdot v^2$ that's just one again.

So 1 by 6 into v^2 without the constant minus 1 2 1, that is 1 minus 1 by 2 plus 1 by 6, what is that? 2 by 3, 1 minus 1 by 3, minus 1 by 2 minus 1 by 6 minus 2 by 3. Please check this calculations so if you look at the dot product of this vector with v^1 and v^2 that is zero this will go with minus 1 minus 1 minus 2 plus 2 zero and w^3 what is the norm of w^3 ? v^3 is w^3 by norm w^3 , norm of w^3 is 4 by 9 into 3 that is 4 by 3 so root 3 by 2 into 2 by 3 into 1, 1, minus 1, so that is 1 by root 3 1, 1, minus 1 that is v^3 . So you can now verify that norm v^3 is 1 and we have already verify that this is orthogonal to the vectors v^1 and v^2 ok. So this gives an orthonormal basis.

(Refer Slide Time: 11:42)

$$= \left(\frac{2}{3}, \frac{2}{3}, -\frac{2}{3}\right) = \frac{2}{3}(1, 1, -1)$$

$$v^3 = \frac{w^3}{\|w^3\|} = \frac{\sqrt{3}}{2} \cdot \frac{2}{3}(1, 1, -1) = \frac{1}{\sqrt{3}}(1, 1, -1)$$

So, $\left\{ \frac{1}{\sqrt{2}}(1, 0, 1), \frac{1}{\sqrt{6}}(-1, 2, 1), \frac{1}{\sqrt{3}}(1, 1, -1) \right\}$ is
an orthonormal basis.

So let me just summarize v_1 is here, $\frac{1}{\sqrt{2}}(1, 0, 1)$ v_2 is here $\frac{1}{\sqrt{6}}(-1, 2, 1)$ and v_3 is here $\frac{1}{\sqrt{3}}(1, 1, -1)$. So this is what we get after applying the GS process which has the required properties that span of v_1 the span of u_1 span of u_1 u_2 span of v_1 v_2 span of v_1 v_2 v_3 span of u_1 u_2 u_3 ok. So this is corresponding to the discrete case that is finite dimensional case. Lets look at a linearly independent set coming from C^0 lets say C minus 1, 1.

(Refer Slide Time: 12:51)

$$2. V = C([-1, 3]) \quad \langle f, g \rangle = \int_{-1}^3 f(t)g(t) dt, \quad f, g \in V$$

So I wanted to do one example coming from C minus 1, 1 with the usual inner product ok.

(Refer Slide Time: 13:22)

$$\begin{aligned}f_0(t) &= 1 \quad \forall t \in [-1, 1] \\f_1(t) &= t \quad \forall t \in [-1, 1] \\f_2(t) &= t^2 \quad \forall t \in [-1, 1].\end{aligned}$$
$$\|f_0\|^2 = \int_{-1}^1 1 \, dt = 2. \quad \|f_0\| = \sqrt{2}$$

So let me start with the usual linearly independent set. So let's say I have f_0 of t is 1, f_1 of t is t , f_2 of t is t^2 , so I just take this set. This vector space has an infinite basis consisting of infinitely many elements. So I am just taking three linearly independent functions. I want to apply the Gram-Schmidt process for this set and obtain an orthonormal set of functions, okay.

This will involve computing integrals, okay. What is the norm of f_0 ? See I will use f_0 and f_1 as the intermediate w 's. I will use f_2 as the next w , okay. What is the norm of f_0 ? Integral from -1 to 1 of f_0^2 dt that is just dt one times dt which is 2. The norm of f_0 squared is 2 and so the norm of f_0 is $\sqrt{2}$. I said I will define g_1 as $f_0 / \sqrt{2}$.

(Refer Slide Time: 14:52)

$$\|f_0\|^2 = \int_{-1}^1 1 \cdot dt = 2 \quad \|f_0\| = \sqrt{2}$$
$$g_0(t) = \frac{1}{\sqrt{2}}$$
$$h_1(t) = f_1 - \langle f_1, g_0 \rangle g_0$$

So G of t I will define that as 1 by $\sqrt{2}$ then this has norm 1 ok, this is the first vector, this is V_1 . Construct the second function which is orthogonal to this function with respect to this inner product. The procedure I will use H from G knot we are trying to construct G_1 so I will use H_1 , H_1 of t is, is that F knot and G knot, see G knot is f knot by norm F knot ok, H_1 of t is so what is the formula? I take the second vector, I must take the second vector so that is F_1 that is what I start with, F_1 of t minus ok let me write without t , F_1 minus F_1 G knot G knot is that ok?

This are my U 's this are my V 's W 's will be my H F knot is a first vector, F_1 is a second vector.

(Refer Slide Time: 16:21)

$$h_1 = f_1 - (f_1, g_0)g_0$$

$$(f_1, g_0) = 0$$

$$\|h_1\|^2 = \int_{-1}^1 t^2 dt = \frac{2}{3}$$

So what is inner product F1 with G knot? Odd function that zero, so it is just F1 is that ok, F1 zero's G0 is 0 which means H1 is just F1 and I have to just divide by norm F1. So what is norm H1? That's norm F1 minus 1 to 1 t square, 1 by 3 and you apply its 2 by 3 or what, yes norm square is 2 by 3 ok.

(Refer Slide Time: 17:17)

$$g_1 = \frac{h_1}{\|h_1\|} = \frac{\sqrt{3}}{2}t$$

$$h_2 = f_2 - (f_2, g_0)g_0 - (f_2, g_1)g_1$$

So what is my G1, G1 is H1 by norm H1 root 3 by 2, H1 is just F1, F1 is t ok this is H1 sorry this is G1.

Finally I need G_2 so I need W_2 which is my H_2 . H_2 is F_2 minus $F_2 G \text{ knot}$ $G \text{ knot}$ minus $F_2 G_1$. $F_2 G \text{ knot}$ F_2 is t^2 $G \text{ knot}$ so this is an odd (dot) even functions that is not zero $F_2 G_1$ F_2 with G_1 that becomes an odd function so that second term is third term is zero.

(Refer Slide Time: 18:24)

$$\langle f_2, g_0 \rangle = \frac{1}{\sqrt{2}} \int_{-1}^1 t^2 dt = \frac{\sqrt{2}}{3}$$

$$h_2 = t^2 - \frac{\sqrt{2}}{3} \cdot \frac{1}{\sqrt{2}} = t^2 - \frac{1}{3}$$

So this is F , ok what is $F_2 G \text{ knot}$? Minus 1 to 1 t^2 and $G \text{ knot}$ is constant, so 1 by root 2 I want F_2 , F_2 is t^2 , so that is 2 by 3 root 2 by 3 just root 2 by 3 is that correct, 1 by 3 and 2 by 3 that gets cancelled root 2 by 3 that is $F_2 G \text{ knot}$ that is this term so H_2 is F_2 , F_2 is t^2 minus $F_2 G \text{ knot}$ is root 2 by 3 into $G \text{ knot}$, $G \text{ knot}$ is just 1 by root 2. This is t^2 minus 1, 1 by 3.

Finally we need to compute the norm of this and then divide H_2 by the norm that's G_2 ok.

(Refer Slide Time: 19:32)

$$\langle f_2, g_0 \rangle = \frac{1}{\sqrt{2}} \int_{-1}^1 t^2 dt = \frac{\sqrt{2}}{3}$$

$$h_2 = t^2 - \frac{\sqrt{2}}{3} \cdot \frac{1}{\sqrt{2}} = t^2 - \frac{1}{3}$$

$$\|h_2\|^2 = \int_{-1}^1 (t^2 - \frac{1}{3})^2 dt = \frac{2}{5} - \frac{4}{9} + \frac{2}{9} = \frac{8}{9}$$

So what is norm of H2? Minus 1 to 1 t square minus 1 by 3 dt that is 2 by 3 minus sorry ok so let do the calculation t square (())(20:05) whole power 2 that is t power 4 can we do mental calculation hopefully not make mistakes that's t power 4, t power 4 is 1 by 5, 2 by 5 minus 2 t square by 3, minus 2 by 3 t square, minus 4 by 9 and plus 1 by 3 into 2 by 3 is this correct, whole square. 2 by 5 minus 2 by 9 so what is the 8 by 9 that is norm square so 45 yes.

(Refer Slide Time: 21:00)

$$g_2 = \frac{h_2}{\|h_2\|} = \frac{3\sqrt{5}}{2\sqrt{2}} (t^2 - \frac{1}{3})$$

$$\left\{ \frac{1}{\sqrt{2}}, \sqrt{\frac{3}{2}} t, \frac{3\sqrt{5}}{2\sqrt{2}} (t^2 - \frac{1}{3}) \right\}$$

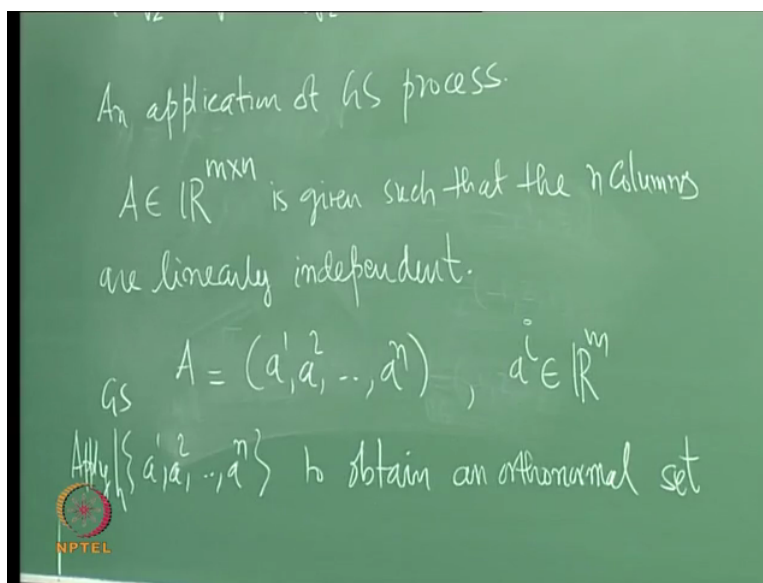

Which means my G2 is H2 by norm H2 that is 45, 9 into 5 that is 3 root 5 by root 8 that is 2 root 2 into H2, H2 is t square minus 1 by 3 is that ok.

Root 45 by root 8, see the computations are $(\frac{1}{2})^{21:36}$ the only thing is this is a little more complicated but what is the moral of the story, let me write down these functions that we have got. G_0 is the constant function 1, G_1 is the function $2t$ and G_2 is the function $3t^2 - 1$ etc. See these functions appear have you seen these functions? Multiple of constant, multiple of t , multiple of $t^2 - 1$ etc.

That is the purpose of giving you this example the functions G_0, G_1, G_2 etc are Legendre polynomials. Legendre polynomials come when you model certain physical problems Legendre differential equations these are the Legendre polynomials ok.

They have some nice properties which you must have studied in your differential equations course, you apply what is called as the power series method to the differential equation and for some values of n you get polynomial solutions, these are those polynomials ok. So just to tell you that these are not different, they are interconnected differential equations linear algebra and many other subjects they are all interconnected only to illustrate that point I wanted to do this example ok. Ok that is GS process and examples I want to discuss one application of the GS process, let's look at the following it might appear to be a completely different situation but you can apply the GS process to infer the following.

(Refer Slide Time: 23:50)

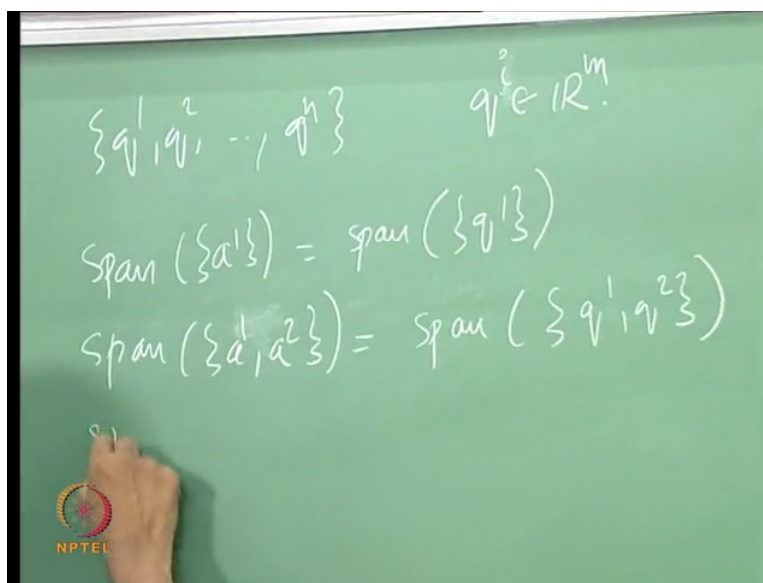

So I want to discuss an application, see what I would like to do let me tell you that beforehand is to derive certain decomposition for matrix with real or complex entries given that the columns are linearly independent ok it is called as a QR decomposition. So what exactly is a problem.

Lets say we are given a matrix A in terms (24:27) so we have a matrix with m rows and n columns, this is given such that the n columns are linearly independent let me denote the n columns by $A_1 A_2$ etc so I am writing A as $a_1 a_2$ etc a n the n columns so each a_i is a column a_i is the i th column of A and lets also remember that a_i belongs to \mathbb{R}^m ok, there are m rows so I am writing A just by using the columns of A . Now this columns are linearly dependent so I consider the set $a_1 a_1$ etc a n this is a linearly independent set of vectors I apply Gram-Schmidt process apply GS to this I get the following set I get an orthonormal set of vectors to obtain an orthonormal set.

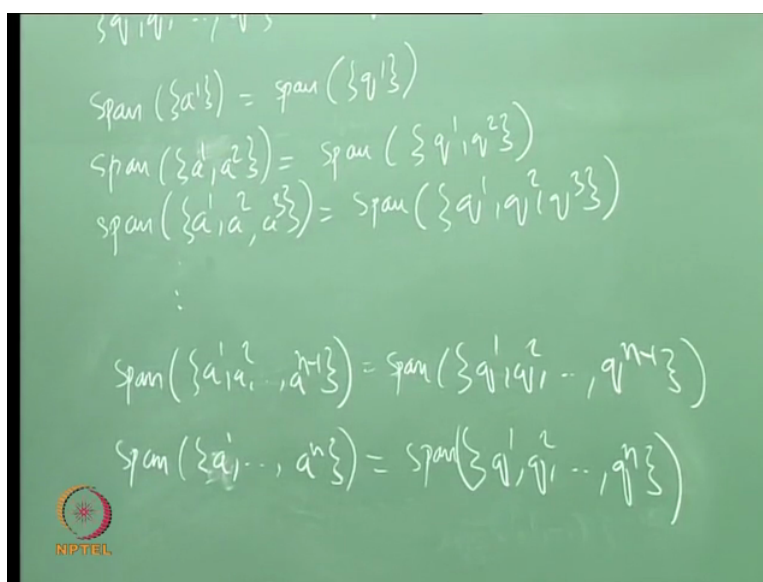

Given a matrix A with linearly independent columns the rectangular matrix with linearly independent columns consider the column vectors are linearly independent vectors apply Gram Schmidt process to get orthonormal vectors n orthonormal vectors in \mathbb{R}^m .

(Refer Slide Time: 26:26)

I will call those vectors q_1, q_2 etc just to emphasize ok that each of these vectors belong to each belongs to \mathbb{R}^m . There are some properties right that these two sets together satisfy let me write down. Span of a_1 is span of q_1 which means q_1 is a multiple of a_1 infact that is how we construct span of a_2 sorry a_1, a_2 this is span of q_1, q_2 .

(Refer Slide Time: 27:17)

I will just write one more and write down the last relation a_1, a_2, a_3 this is span of q_1, q_2, q_3 etc we can proceed in this manner.

The last step is span of a_1, a_2, \dots, a_{n-1} that is equal to span of q_1, q_2, \dots, q_{n-1} and finally span of a_1, a_2, \dots, a_n is span of q_1, q_2, \dots, q_n . So we have these equations between subspaces.

(Refer Slide Time: 28:24)

$$\text{Span}(\{a_1, a_2, \dots, a_{n-1}\}) = \text{Span}(\{q_1, q_2, \dots, q_{n-1}\})$$

$$\text{Span}(\{a_1, a_2, \dots, a_n\}) = \text{Span}(\{q_1, q_2, \dots, q_n\})$$

So,

$$a_1 = r_{11}q_1$$

$$a_2 = r_{12}q_1 + r_{22}q_2$$

$$a_{n-1} = r_{1,n-1}q_1 + r_{2,n-1}q_2 + \dots + r_{n-1,n-1}q_{n-1}$$

$$a_n = r_{1n}q_1 + \dots + r_{nn}q_n$$

Write down the first equation from this a_1 is a multiple of q_1 , q_1 is a multiple of a_1 really but that is a non-zero multiple you can divide. So a_1 is a multiple of q_1 I will call it $r_{11}q_1$. Look at the second look at a_2 , a_2 belongs to span a_1, a_2 and so it belongs to span q_1, q_2 so a_2 is a linear combination of q_1 and q_2 .

I can write a_2 as a linear combination of q_1, q_2 I will write it as $r_{12}q_1$ plus $r_{22}q_2$ the next equation is similar ok I will proceed like this the last one gives me a_{n-1} is $r_{1,n-1}q_1, r_{2,n-1}q_2$ the second the is fixed it is the first one that changes $r_{2,n-1}q_2$ etc plus you go only upto the $n-1$ th term $r_{n-1,n-1}q_{n-1}$ the last one will have all the n terms let me write the last one a_n is $r_{1n}q_1$ etc $r_{nn}q_n$ ok can you see it when I write it here? Ok can r_{11} be zero? Can be zero because I started with a linearly independent set so zero is not present if r_{11} is zero it means a_1 is zero that is not possible, can r_{22} be zero?

Suppose r_{22} is zero then I am writing q_1 in term a_2 in terms of q_1 , q_1 in term can be written in terms of a_1 so I am writing a_2 in terms of a_1 not possible a_1, a_2 are independent etc $r_{n-1,n-1}$ can that be zero for the same reason it cant be zero. If it is zero then I am able to write q_1 etc q_{n-2} I am able to write a_{n-1} in terms of q_1 etc q_{n-2} that is a_1 etc a_{n-2} which means a_1 etc a_{n-2} , a_{n-1} is linearly dependent

that is not possible. So all these last coefficients are non-zero ok. So I form a if I form a matrix with this as diagonal entries let us say a triangular matrix that matrix should be invertible.

(Refer Slide Time: 31:25)

So lets say we call the matrix R as so I have written it in that manner r_{11} r_{12} etc r_{1n} this entry is zero r_{22} etc r_{2n} 00 r_{3n} etc all these entries are zero the last entries are n n , this is no matrix R, there is an upper triangular matrix the lower the entries beyond the below the principle diagonal are zero and the diagonal entries are not zero. Note r_{ii} is not zero for all i and so this is an invertible matrix ok this is an invertible matrix the diagonal entries are not zero this is invertible.

So if you look at QR for instance what is Q? Q is my matrix whose columns are q_1 q_2 etc q_n into r_{11} r_{12} . See if you look at this matrix QR then can you see that this is see you do this multiplication r_{11} into q_1 plus this entry into q_2 etc into q_n which means I have only one term $r_{11} q_1$.

(Refer Slide Time: 32:59)

$$= (r_{11}q^1, r_{12}q^1 + r_{22}q^2, \dots, r_{1n}q^1 + \dots + r_{nn}q^n)$$
$$= (a^1, a^2, \dots, a^n) = A$$

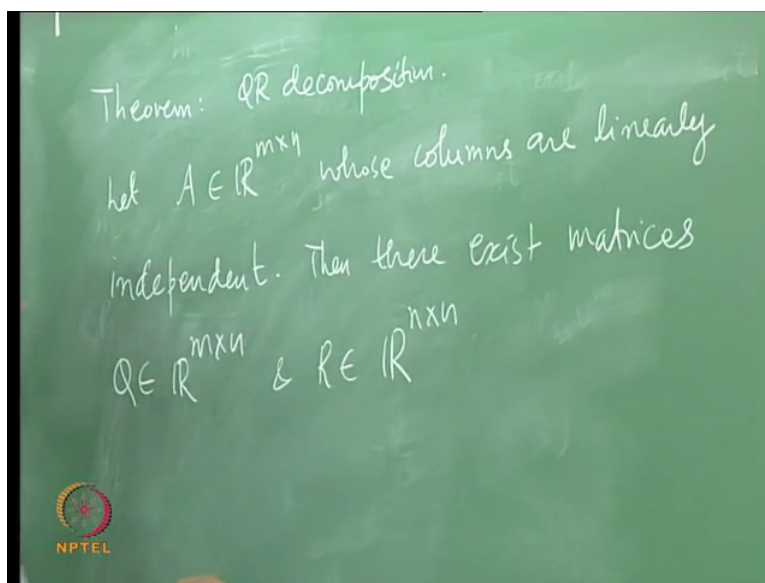

Further $Q^t Q = I_n$

The next one is r_{12} sorry the next one is $r_{12} q_1$ plus $r_{22} q_2$ $r_{12} q_1$ plus $r_{22} q_2$ etc the last one has all these terms, $r_{1n} q_1$ etc $r_{nn} q_n$ ok, but what this is already there this equation is already there. $r_{11} q_1$ is a_1 $r_{12} q_1$ plus $r_{22} q_2$ that is a_2 etc that is a n which is the matrix that we started with. So Q times R is A this is called the QR decomposition of a matrix given that the columns of the matrix are linearly independent.

We have not said anything about we have not made use of the fact that the Q_i 's are orthogonal orthonormal in fact, what happens to this? See remember Q is a rectangular matrix the order of Q is same as order of A so Q is m cross n ok. Q transpose Q is n cross n ok, what can you say about n cross Q transpose Q ? What is Q transpose Q ? Or what do you know about the columns of, can you see its identity? See its identity of order n Q transpose Q the identity of order n but if you look at Q Q transpose you can't expect that to be this because in the first place Q Q transpose is of order m ok. Such a matrix is called an orthogonal matrix.

See this is a matrix with real entries such a matrix is called an orthogonal matrix if you have a matrix with complex entries that satisfies this $Q^* Q = I$ it is called unitary matrix in the rectangular case, in the square case let's remember that in the square if Q transpose Q is identity then Q Q transpose also has to be identity ok. So this matrix Q has this extra property that comes primarily from the fact that the columns are orthonormal vectors ok.

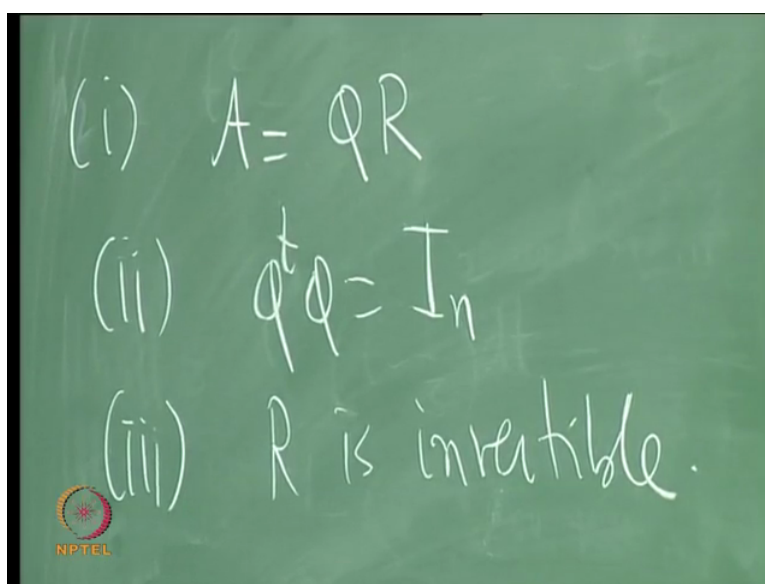

(Refer Slide Time: 35:44)

So what we have proved is the following theorem, Q R decomposition. Let A belong to $\mathbb{R}^{m \times n}$ with whose columns ok, let me write like this whose columns are linearly independent then there exists matrixes Q and R Q has the same order as A.

There exists matrix is Q in $\mathbb{R}^{m \times n}$ and R in $\mathbb{R}^{n \times n}$ R is a square matrix such that the following condition holds.

(Refer Slide Time: 36:54)

The first one is this decomposition A is Q times r second condition Q transpose Q is identity of order n and the third condition third property is that R is invertible ok. The idea behind

studying decompositions of a matrix is that the question about problems involving the matrix A can be reduced to questions about problems involving QR , it gives a kind of a reduction. I will explain that a little later but let's maybe work out an example. Ok so we had this theorem has been proved.

(Refer Slide Time: 38:01)

$$A = \begin{pmatrix} 1 & 0 & 1 \\ 0 & 1 & 1 \\ 1 & 1 & 0 \end{pmatrix}$$

$$a^1 = (1, 0, 1)^t$$

$$a^2 = (0, 1, 1)^t$$

$$a^3 = (1, 1, 0)^t$$

Let's look at an example that we have done before today this Gram Schmidt process for the first example so can you just tell me those vectors, let's say the matrix A the three vectors a_1 , a_2 , a_3 , what is the first one? $1\ 0\ 1$, $1\ 0\ 1$, $0\ 1\ 1$, $1\ 1\ 0$ these are linearly independent vectors. So I have a_1 as $1\ 0\ 1$, a_2 is $0\ 1\ 1$, a_3 is $1\ 1\ 0$ see by the way I am when I write vectors I interchangeably write them as rows and columns from the context it should be clear whether it is a row or a column, it is only for convenience that I write it as a row vector but remember that a_1 , a_2 , a_3 are the column vectors of A ok. So strictly speaking I must write transpose ok but at times I might omit that but just make sure that the compatibility, matrix multiplication etc that is done correctly, that is appropriate.

(Refer Slide Time: 39:07)

$$q^1 = \frac{1}{\sqrt{2}} (1, 0, 1)^t$$
$$q^2 = \frac{1}{\sqrt{6}} (-1, 2, 1)^t$$
$$q^3 = \frac{1}{\sqrt{3}} (-1, 1, -1)^t$$
$$Q = \begin{pmatrix} \frac{1}{\sqrt{2}} & -\frac{1}{\sqrt{6}} & \frac{1}{\sqrt{3}} \\ 0 & \frac{2}{\sqrt{6}} & \frac{1}{\sqrt{3}} \\ \frac{1}{\sqrt{2}} & \frac{1}{\sqrt{6}} & -\frac{1}{\sqrt{3}} \end{pmatrix}$$

So these are the vectors we obtain q_1 q_2 q_3 so q_1 I can write down $1/\sqrt{2}$ into $1/\sqrt{2}$ 0 $1/\sqrt{2}$, q_2 you should tell me, $-1/\sqrt{6}$ $2/\sqrt{6}$ $1/\sqrt{6}$ no, $-1/\sqrt{6}$ $2/\sqrt{6}$ $1/\sqrt{6}$ q_2 ? Is this correct? Ok and q_3 I remember $1/\sqrt{3}$ at must that much $-1/\sqrt{3}$ $1/\sqrt{3}$ ok. So the matrix Q in this problem is ok you have to just write down all this $1/\sqrt{2}$ 0 , $1/\sqrt{2}$, $-1/\sqrt{6}$, $2/\sqrt{6}$, $1/\sqrt{6}$, $1/\sqrt{3}$, $1/\sqrt{3}$, $-1/\sqrt{3}$ this is my Q . See to determine R I need to solve those equation but that is not necessary.

(Refer Slide Time: 40:28)

$$A = QR$$
$$Q^t A = Q^t QR = R$$

So $R = \begin{pmatrix} 1/\sqrt{2} & 0 & 1/\sqrt{2} \\ -1/\sqrt{2} & 2/\sqrt{6} & 1/\sqrt{6} \\ 1/\sqrt{3} & 1/\sqrt{3} & -1/\sqrt{3} \end{pmatrix}$

(Refer Slide Time: 42:05)

$$A = QR$$
$$Q^t A = Q^t QR = R$$

So $R = \begin{pmatrix} 1/\sqrt{2} & 0 & 1/\sqrt{2} \\ -1/\sqrt{2} & 2/\sqrt{6} & 1/\sqrt{6} \\ 1/\sqrt{3} & 1/\sqrt{3} & -1/\sqrt{3} \end{pmatrix} \begin{pmatrix} 1 & 0 & 1 \\ 0 & 1 & 1 \\ 1 & 1 & 0 \end{pmatrix}$

$$= \begin{pmatrix} \sqrt{2} & 1/\sqrt{2} & 1/\sqrt{2} \\ 0 & 3/\sqrt{6} & 1/\sqrt{6} \\ 0 & 0 & 2/\sqrt{3} \end{pmatrix}$$

See A is QR ok I will do that A is QR I can pre-multiply by Q transpose, Q transpose A is Q transpose QR this where we use the second property, this is just R.

So R is Q transpose A, so just do the multiplication matrix multiplication to get R, R must be an upper triangular matrix I am not simplifying just leaving the fractions as they are, ok this is R ok so computationally you don't have to solve those equations so the property that Q transpose Q equal to I saves effort of computing R ok just pre-multiply do one matrix multiplication which is much easier ok. Let me stop here and discuss in other application of

QR with regard to what are called as least square solutions of linear systems ok. So I will stop here.
