**Lecture 8**  
**Vector Spaces**

So in today's lecture we look at the notion of a vector space. Almost all of us have done vector calculus involving two variables three variables, for example look at vectors in the plane we have done vector addition and then multiplying a vector by a scalar we have for example this is called a linear combination of vectors we have also encountered linear combination of functions especially when we have discussed the notion of solutions of differential equations if  $y_1$  and  $y_2$  are two solutions of a linear differential equation then a linear combination  $\alpha y_1 + \beta y_2$  is also a solution of the differential equation.

The structure that formalizes this notion of linear combination etcetera is called a vector space this is a basic object of linear algebra. So what I will do is today give the definition of a vector space and then give a variety of examples just to tell you that vector spaces abound in the whole of mathematics. So these examples for instance will include the differential calculus example that I mentioned and also other examples, okay.

(Refer Slide Time: 1:49)

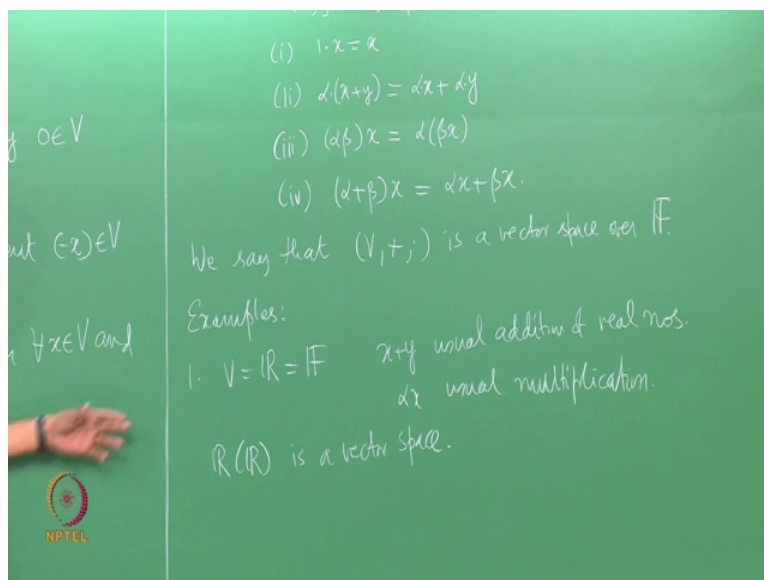

So let us look at first the notion of a vector space, so here is the definition a vector space consist of the following consist of the first object is field so we say vector space over a field the first object is if a field we say that it is a field of scalars in this entire course of linear algebra we will restrict our attention mostly  $\mathbb{R}$  and in some examples we complex a field also, then we have  $V$  a set of elements  $V$  of course is non-empty set of elements these elements are called vectors then third aspect is a rule called vector addition a rule called vector addition this is a binary operation which for  $x, y$  in  $V$  assigns a unique vector which we will denote as  $x$  plus  $y$  this  $x$  plus  $y$  belongs to  $V$ , okay so there is a binary operation on  $V$  it is called the vector addition this binary operation satisfies the following conditions, okay for every  $x, y$  in  $V$  there is a unique  $x$  plus  $y$  which also belongs in  $V$  so it is closed to respect to this operation such that the following conditions are satisfied such that lets write these conditions here, first it is commutative  $x$  plus  $y$  equals  $y$  plus  $x$  second condition its associative  $x$  plus  $y$  plus  $z$  equals  $x$  plus  $y$  plus  $z$  so that is associativity.

Condition 3, for every, I am sorry it is a condition 3, condition 3 there exist an element denoted by  $0$  that is in  $V$  such that so this  $0$  acts like additive identity so we have this condition to be satisfied such that  $x$  plus  $0$  equals  $x$ , okay. See all these are for all  $x, y, z$  in  $V$  so such that this holds for all  $x$  in  $V$  and the last condition the fourth condition is that for every  $x$  in  $V$  there exist an element which we denote as minus  $x$  this minus  $x$  belongs to  $V$  such that this is like the negative additive inverse negative element such that  $x$  plus minus  $x$  equals the additive identity, alright? So these conditions hold for all  $x, y, z$  in  $V$  so this is with respect to the vector addition operation this four conditions must be satisfied.

So we have so a vector space has a field so there is field over which the vector space is defined there is  $V$  a set of vector satisfying these four conditions, now what is the interaction between the field elements and the vector elements that is given by scalar multiplication, so I will say four a rule called scalar multiplication which for every  $x$  in  $V$  and a scalar  $\alpha$  in  $F$  which for every  $x$  in  $V$   $\alpha$  assigns  $\alpha$  in  $F$  assigns a number  $\alpha$  times  $x$  in  $V$ . So for every  $x$  in  $V$   $\alpha$  in  $F$  this product this scalar multiplication  $\alpha$  times  $x$  must be in  $V$  and this scalar multiplication must satisfy the following four conditions so what are those conditions, remember the underlying remember that  $F$  is a field so  $F$  for instance has  $0$  as well as  $1$ ,  $1$  is the multiplicative identity.

(Refer Slide Time: 7:17)

So the first condition relates uses the multiplicative identity so I will again write four conditions for the scalar multiplications  $1 \cdot x$  equals  $x$  so for all  $x, y$  in  $V$  and for all  $\alpha, \beta$  in  $F$  so I have this condition  $1 \cdot x$  equal to  $x$ , condition 2  $\alpha(x+y)$  equals  $\alpha x + \alpha y$  I should actually write a dot here we will follow the convention of not using this dot  $\alpha(x+y)$  is  $\alpha x + \alpha y$ .

Condition 3, is if you look at  $\alpha\beta$  of  $x$  it says you do it repeatedly this is  $\alpha$  into  $\beta x$  and finally condition 4 is you take scalars  $\alpha$  and  $\beta$  look at  $(\alpha+\beta)x$  this must be  $\alpha x + \beta x$ . So the scalar multiplication must satisfy these 4 conditions the vector addition must satisfy these 4 conditions the underlying set  $F$  must be a field then  $V$  is

called a vector space over  $F$ , so in this case we say that  $V$  plus dot is a vector space over  $F$  so this is a formal definition of a vector space, alright?

Let us look at some examples, now before we proceed with the examples let us understand that the two examples that I told you in some sense as motivating examples satisfy these conditions example of two solutions coming from differential equation and the behavior of vectors in the plane for instance, so let us look at some examples I will give an abundance of examples just to illustrate that this is an absolutely fundamental object in mathematics not just in linear algebra.

So let us look at examples let us start with the simplest example you take  $V$  as  $\mathbb{R}$  also the underlying field as  $\mathbb{R}$  then we know that then addition is what  $x$  plus  $y$  is the usual addition usual addition of real numbers scalar multiplication is also the usual multiplication then this is a vector space  $V$  over  $F$  is a vector space that is we say that  $\mathbb{R}$  is a vector space we will follow this notation only for this today's lecture we will simply say  $\mathbb{R}$  is a real vector space,  $\mathbb{C}$  is a complex vector space etcetera.

So  $\mathbb{R}$  over  $\mathbb{R}$  is a vector space as I said we can also say that  $\mathbb{R}$  is a real vector space. So this is the basic example similarly one could define  $\mathbb{C}$  as a vector space over itself. In general any field over itself is a vector space over that field.

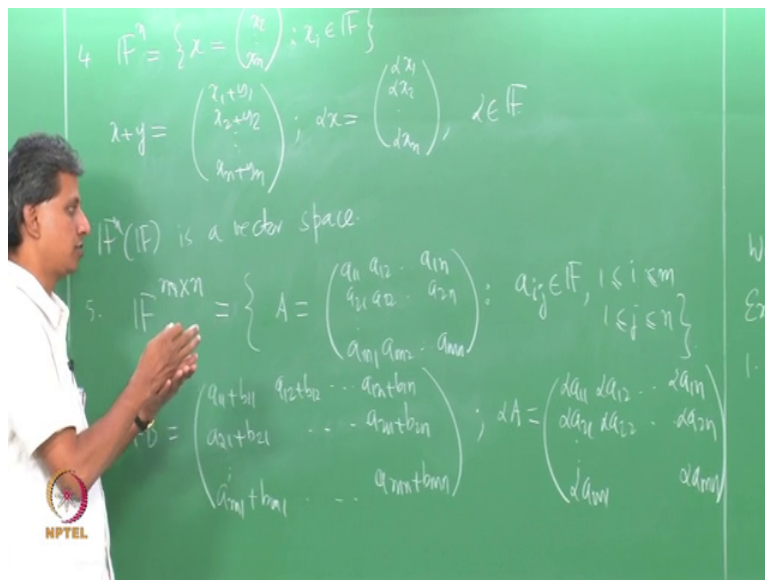

(Refer Slide Time: 11:01)

Second example is also trivial take  $V$  to be single term  $0$  and  $F$  is any field you have to define see you must define vector addition scalar multiplication vector addition is defined like this scalar multiplication  $\alpha \times 0 = 0$  for all  $\alpha$  in  $F$  then this is a vector space  $V$  over  $F$  is a vector space over the field  $F$ , okay these are trivial examples let us look at the first non-trivial example look at  $F^2$ ,  $F^2$  is what?  $F^2$  is the set of all vectors  $x$  written in this manner  $x = (x_1, x_2)$  so I will write it as a column vector set of all  $x_1, x_2$  such that  $x_1$  and  $x_2$  both belong to the underlying field so this is  $F^2$ , okay set of all columns which  $(\ )$  (12:00) which have just two coordinates which have just two components, what is vector addition scalar multiplication once I specify that we can verify whether it is a vector space.

So let us take two elements  $x, y$  in  $F^2$  then  $x$  can be written as  $x_1, x_2$   $y$  can be similarly written  $y_1, y_2$  let us also take  $\alpha$  in the underlying field then  $x + y$  we will define  $x + y$  to be the column vector the natural way to define addition is  $x_1 + y_1$  that is the first coordinate  $x_2 + y_2$  is the second coordinate this is obviously a binary relation scalar multiplication  $\alpha x$  you do it for each coordinate multiply the scalar  $\alpha$  to each coordinate  $\alpha x_1 \alpha x_2$  then it is an easy exercise to verify that  $F^2$  over  $F$  that is  $V = F^2$  so  $V$  over  $F$  is a vector space with respect to this addition operation and this scalar multiplication, okay.

(Refer Slide Time: 13:25)

Now we can do a little more general so let us look at  $F^n$ ,  $F^n$  this times is the set of all  $x$  that can be written as  $x_1, x_2$  etcetera  $x_n$  so there are  $n$  coordinates this times such that each  $x_i$  comes from

the underlying field this simply extends  $F$  that was given in the previous example how do you define addition as before coordinate wise  $x_1$  plus  $y_1$ ,  $x_2$  plus  $y_2$  etcetera  $x_n$  plus  $y_n$ .

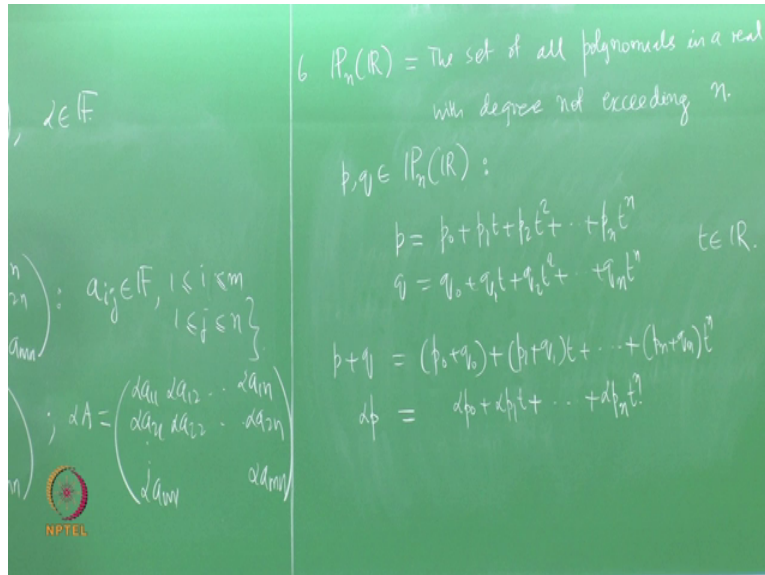

So  $x$  is this  $y$  is  $y_1, y_2$  etcetera  $y_n$  addition is defined in this manner scalar multiplication is similarly for  $\alpha$  in the underlying field then again we can show that  $F^n$  over  $F$  is a vector space with respect to these operations, okay so this is a little extension of the third example we can do a little more general let us look at  $F^{m \times n}$ , now this  $m \times n$  should suggest the objects that we are considering here so what is the definition here this is the set of all  $x$  such that  $x$  has  $m$  into  $n$  coordinates that is one way of looking at it which will give rise to the same vector space as above a slightly different way of looking at  $F^{m \times n}$  which is the set of all  $A$  which can be written as  $A_{11}, A_{12},$  etcetera  $A_{1n}$  so this is set of all  $m \times n$  matrices, matrices with entries coming from the underlying field which matrices which have  $m$  rows and  $n$  columns  $a_{11}$  etcetera  $a_{1n}$   $a_{21}, a_{22}$  etcetera  $a_{2n}$  let me write the last row  $a_{m1}, a_{m2}$  etcetera  $a_{mn}$ .

So these numbers  $a_{ij}$  they all come from  $F$   $1 \leq i \leq m$   $1 \leq j \leq n$  such an object is called a matrix so you collect the set of all matrices with the property that the matrices have  $m$  rows and  $n$  columns the entries of the matrix come from the underlying field  $F$  then again the operations of vector addition and scalar multiplication is natural, by the way here it is addition of matrices but still we refer to it as vector addition that is each element in  $F^{m \times n}$  will be referred to as a vector, okay now this is the terminology that we will adopt. So a vector will not denote any more objects on the plane or objects on the three dimensional space they can now denote matrices we will do a little more general we will use vectors to denote polynomials, we will use vectors to denote solutions of differential equations etcetera, okay.

So let us look at vector addition scalar multiplication so take two matrices  $A$  and  $B$   $A$  written in this manner  $B$  written in a similar manner then  $A$  plus  $B$  is coordinate wise addition, so  $A$  plus  $B$  is  $a_{11}$  plus  $b_{11}$ ,  $a_{12}$  plus  $b_{12}$  etcetera  $a_{1n}$  plus  $b_{1n}$ ,  $a_{21}$  plus  $b_{21}$  etcetera  $a_{2n}$  plus  $b_{2n}$  similarly the last column last row  $a_{m1}$  plus  $b_{m1}$  etcetera  $a_{mn}$  plus  $b_{mn}$ . So this is how vector addition is defined scalar multiplication as before  $\alpha$  times  $A$  will be you multiply each entry by the scalar  $\alpha$   $\alpha a_{11}, \alpha a_{12}$  etcetera  $\alpha a_{1n}$ ,  $\alpha a_{21}$   $\alpha a_{22}$  etcetera  $\alpha a_{2n}$  etcetera  $\alpha a_{m1}$   $\alpha a_{mn}$ , so this is how scalar multiplication is defined again one can verify that  $F^{m \times n}$  over  $F$  is a vector space.

See for instance the 0 element will be the 0 matrix the matrix all of whose entries are 0 the negative element of an element A will be the matrix whose entries are the negatives of the corresponding entries of the matrix A etcetera.

(Refer Slide Time: 18:07)

So this is another vector space example of vector space let us next look at  $P_n$  for instance, what is  $P_n$ ?  $P_n$  equals the set of all polynomials in a real variable  $t$  with degree of the polynomial not exceeding the degree not exceeding the number  $n$  that is used as a subscript here.

So it is set of all polynomials of degree less than or equal to  $n$  polynomial in what polynomial in one single real variable  $t$  that is what is denoted by this  $R$ , okay. Now for example if  $P, q$  belong to  $P_n$  of  $R$  then these are polynomials I can write polynomials in the following manner  $P$  can be written as  $p_0$  plus  $p_1 t$  plus  $p_2 t^2$  etcetera plus  $p_n t^n$  remember some of these constants  $p_0, p_1, p_2$  etcetera  $p_n$  some of these constants could be 0 because it is a set of all polynomials of degree not exceeding  $n$  that degree could be less than  $n$  in which case  $p_n$  is 0 for instance similarly  $q = q_0 + q_1 t + q_2 t^2$  etcetera  $t$  is real variable, so I have two elements two vectors now so vectors we are using the name vector for a polynomial here.

So what is vector addition  $p + q$  that is again the natural addition  $p + q$  is defined as so a definition is  $p_0 + q_0 + p_1 t + q_1 t + \dots + p_n t^n + q_n t^n$ , so this is the definition of addition vector addition scalar multiplication also you would simply bring it to the

coefficients, so  $\alpha$  times  $p$  is  $\alpha p$  not  $\alpha p^1 t$  etcetera plus  $\alpha p^n t^n$  then you can again verify that  $V$  is this  $p^n$  is a real vector space, okay so  $p^n$  is a real vector space vector space over the field of real numbers.

(Refer Slide Time: 21:18)

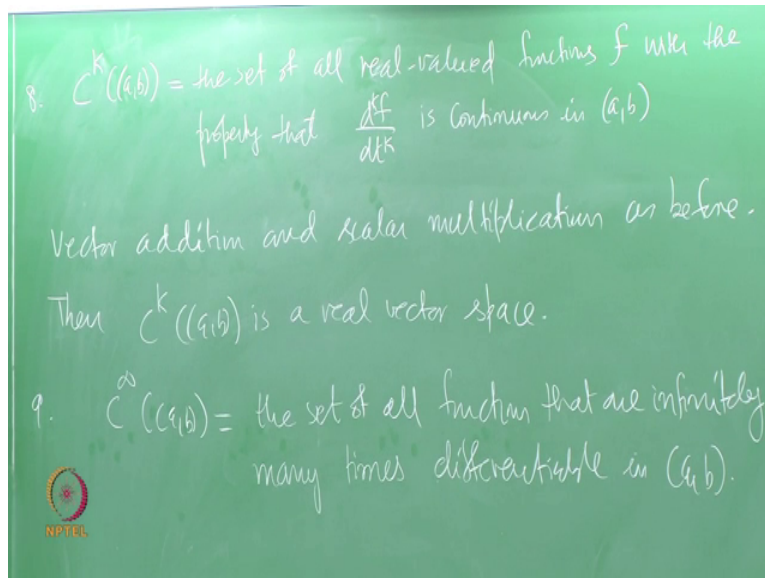

Let us do a little more general let us now look at the space of continuous functions the space of real valued continuous functions on a closed interval  $AB$  the space of real valued continuous functions on the closed interval  $AB$  we should again so I am saying the set of all real valued continuous functions so the underlying field will be  $\mathbb{R}$  we should again define vector addition scalar multiplication you know that is similar to what we have done earlier for the case of polynomials this is so called point wise addition so we will do a similar thing here for  $p, q$  in  $C$  of  $AB$  define  $p$  plus question of  $t$  so  $p$  plus  $q$  is a new function whose definition is  $p$  plus  $q$  at the point  $t$  is  $p$  of  $t$  plus  $q$  of  $t$  and scalar multiplication is defined similarly  $\alpha p$  is a new function it is just  $\alpha$  times  $p$  of  $t$  this is the most natural way of defining it for all  $\alpha$  in  $\mathbb{R}$  for  $p, q$  in  $C$  of  $AB$ .

So it can again be shown that  $C$  of  $AB$  is a real vector space if we replace underlying field by  $\mathbb{C}$  and then consider complex values continuous functions then  $C$  of  $AB$  will be a complex vector space.

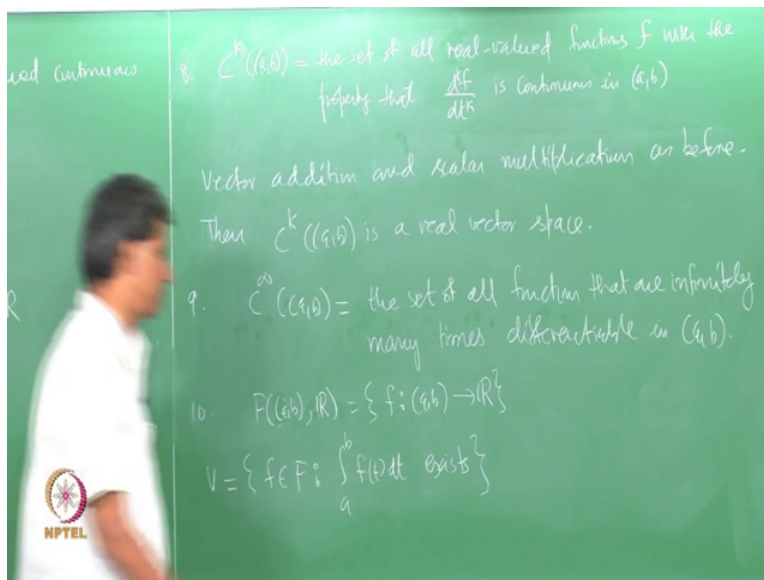

(Refer Slide Time: 23:25)

We can do a little more general let us denote  $C^k$  this time open interval to be the set of all functions real valued functions let me say  $F$  with the property that let us say that I will use the variable  $t$  for any point on the interval  $AB$  so it is  $F$  of  $t$  for instance with the property that  $\frac{d^k f}{dt^k}$  the  $k$ th derivative of  $f$  is continuous the property that  $\frac{d^k f}{dt^k}$  the  $k$ th derivative of  $f$  with respect to of course there is only one variable here the independent variable is  $t$  this is continuous in  $AB$  collect all such functions real valued functions having this property again vector additions scalar multiplication as before vector addition and scalar multiplication as before then this is a vector space is a real vector space we can do a little more general one looks at  $C^\infty$  of  $A$  this is now the set of all functions real valued functions that are infinitely many times differentiable in the interval  $AB$  open interval  $AB$  same operations of vector additions scalar multiplication will tell you that this is a real vector space that is infinity  $AB$ , okay that is infinity  $AB$  let us consider a more let us consider another example I will give it as example 10.

(Refer Slide Time: 26:06)

Let us consider let, okay let me use this notation, okay let me use the notation  $F$  of let me use the notation  $F$  of  $AB$ ,  $AB$  comma  $\mathbb{R}$  to be the set of all functions  $F$  from  $AB$  to  $\mathbb{R}$  set of all real value functions depend on the open interval  $AB$  collect all those functions that is my capital  $F$   $AB$  comma  $\mathbb{R}$ .

Now in this look at  $V$  as the set of all  $F$  and  $F$  such that integral  $A$  to  $B$   $F$  of  $t$   $dt$  exists that is  $f$  is Riemann integrally that is set of all functions that are Riemann integrable then with respect to again usual addition and scalar multiplication we can show that  $V$  is a vector space when  $V$  is a real vector space. Now what is the meaning that this is a vector space if  $F$  Riemann integrable  $G$  is Riemann integrable then  $F$  plus  $G$  is Riemann integrable if  $F$  is Riemann integrable  $\alpha$  is a real number then  $\alpha$  times  $F$  is Riemann integrable, okay.

(Refer Slide Time: 27:31)

Example 11, suppose that we have a matrix  $A$  of order  $m$  by  $n$  so there are  $m$  rows  $n$  columns entries are real numbers defined  $V$  as the set of all vectors  $x$  in  $\mathbb{R}^n$  such that  $Ax = 0$ . Now remember  $A$  is an  $m$  cross  $n$  matrix  $x$  is  $n$  cross  $1$  any vector standing alone is a column vector so when I write a vector as it is it is a column vector, so the product here is  $m$  by  $n$  into  $n$  by  $1$  so it is a usual product of matrices so the resultant is  $m$  cross  $1$  so this  $0$  vector on the right hand side is a  $0$  vector which has  $m$  coordinates.

Now this is a vector space now this is a subset of  $\mathbb{R}^n$ ,  $\mathbb{R}^n$  already has vector addition scalar multiplication defined it can be shown with respect to those operations that  $V$  is a vector space, again close to with respect to addition means what if  $x$  and  $y$  satisfy  $Ax = 0$  and  $Ay = 0$  then  $x + y$  satisfies  $A(x + y) = 0$  because  $A(x + y) = Ax + Ay$ . Similarly, if  $x$  belongs to  $V$  then  $\alpha x$  also belongs to  $V$  because the  $\alpha$  comes out here of this equation  $\alpha$  comes out of this equation.

So this is a vector space we also have another example this the example that I gave as a motivating example let us look at the operator  $L$  defined on a function  $y$  which is at least  $n$  times differentiable  $y$  is a function of the independent variable let us say  $t$  define  $L$  of  $y$  so I am looking at this equation  $L$  of  $y$  equals  $L$  of  $y$  is defined by  $d^n y/dt^n + a_{n-1} d^{n-1} y/dt^{n-1} + \dots + a_1 dy/dt + a_0 y$ , let us so let  $L$  be defined in this manner  $L$  is a differential operator, consider  $V$

as the set of all  $y$  such that set of all  $y$  such that  $L$  of  $y$  equals 0, okay see I must mention here that  $a_1$  etcetera each of these is a function of the independent variable  $t$  each of these is a you can take them as constants in particular but in general they are functions of  $t$ .

Then look at  $V$  as a set of all  $y$  so this you need  $y$  to be at least  $n$  minus you need  $y$  to be  $n$  times differentiable in order for this to be defined, so collect all those functions then that satisfies then collect all those function then such a way such a set is a vector space if you consider  $L$  valued function then it is a real vector space. Let me give you a couple of more examples some intuition coming from geometry, so example 3  $V$  is the set of all  $x$  in  $\mathbb{R}^2$  so this is a subset of  $\mathbb{R}^2$  in fact it is a vector space in its right set of all  $x$  in  $\mathbb{R}^2$  such that  $x_2$  equals alpha times  $x_1$  alpha is a fixed number  $x_2$  is alpha times  $x_1$  alpha is a fixed number, okay.

So which means if you collect the set of all vector which have the property that the second coordinate is alpha times the first coordinate, okay. Now geometrically what does this set represent? This set represents the set of all points passing through the origin this set represents the set of all points lying on a straight line passing through the origin, okay it can be shown again that this is a vector space the set of all points lying on a particular straight line passing through the origin the slope is given by alpha.

(Refer Slide Time: 32:06)

A little more general I will call that as example 14 is the set of all vectors in the three space that satisfy something like  $x_1$  plus  $2a$   $x_2$  plus  $5$   $x_3$  equals 0 geometric interpretation this is the set of

all points lying on a certain plain passing through the origin, okay this can again be shown to be a vector space, okay. So I hope the abundance of this examples illustrate the importance of the notion of a vector space, let me conclude the lecture by giving two by giving at least one example of a subset of  $\mathbb{R}^2$  which is not a vector space.

Example 15, let us look at  $V$  as the set of all  $x$  in  $\mathbb{R}^2$  such that  $x_2$  is  $x_1$  plus 1 the second coordinate is you add 1 to the first coordinate collect all such vectors this is again a straight line the only thing is that this straight line does not pass through the origin you can show that this is not a vector space, okay. Now you must observe that vector space must have  $0, 0$  must belong to the vector space now this one does not have  $0$ , okay so this is not a vector space.

One final example, non-example so this is not a vector space one final example let us say  $V$  equal to the set of all polynomials of degree precisely 2 I do not say degree less than or equal to 2 degree precisely 2, I leave it for you to show that this is not a vector space it is not even close with respect to addition  $V$  is not a vector space, okay. Let me stop here in the next lecture I will discuss the notion of subspaces, examples of subspaces etcetera.
