Lecture - 06
Matrices continued

In the last lecture, we have been reviewing several of the properties of matrices special matrices operations and matrices. We are going to continue the coverage of other properties of matrices that are critical to power analysis.

(Refer Slide Time: 00:37)

EIGENVALUES AND EIGENVECTORS

- Let $A \in \mathbb{R}^{n \times n}$. If there exists $V \in \mathbb{R}^n$ and $\lambda \in \mathbb{R}$ such that $AV = \lambda V$, then λ is the eigenvalue and V is the eigenvector of A
- (λ, V) is the solution of the homogenous system
$$(A - \lambda I)V = 0$$
- For V to be non-trivial vector, $P(\lambda) = \det(A - \lambda I) = 0$ where $P(\lambda)$ is the n^{th} degree polynomial called the characteristic polynomial
- Let $\lambda_1, \lambda_2, \dots, \lambda_n$ be the n -roots of $P(\lambda) = 0$
- λ_i 's are real or complex. Complex roots come in conjugate pairs
- When A is symmetric, λ_i 's are real
- When A is symmetric and positive definite (SPD), λ_i 's are real and positive

The first of the topic in that direction are going to be the notion of Eigenvalues and Eigenvectors of any real matrix let A be a n by n real matrix, if there exists a vector V belonging to \mathbb{R}^n at a constant λ a real \mathbb{R} , a complex constant \mathbb{C} such that $AV = \lambda V$, then λ is called the Eigenvalue and V is called Eigenvector of A .

From the definition, it follows that λV the pair the constant λ and the vector V is a solution of homogeneous system that can be obtained from $AV = \lambda V$ for V to be a non if V is 0. This equation trivially satisfied V is equal to 0 is called the trivial solution, we are seeking non trivial vector; that means, a non-zero vector; for a non-zero vector to solve this equation, it is necessary that the determinant of the matrix A minus λI must be 0. We have earlier seen one of the conditions necessary for the

existence of solution of homogeneous system is the system must be singular, here the system matrix is $A - \lambda I$; the determinant of $A - \lambda I$ must be 0, the determinant of $A - \lambda I$ elements of A are known elements of I are known λ is a variable.

So, it becomes a polynomial of degree n this polynomial $P(\lambda)$ which is the determinant of $A - \lambda I$ is called the characteristic polynomial in n th degree polynomial has the n roots. Let $\lambda_1, \lambda_2, \dots, \lambda_n$ be the n roots of $P(\lambda)$ is equal to 0 from fundamental theorem of arithmetic, we all know that λ s can be either real or complex; complex roots always come in conjugate pairs the reason complex roots come in conjugate pairs is that the elements of the matrix A are real this implies the coefficients of the polynomial $P(\lambda)$ are real and when you are trying to solve a polynomial with real coefficients the roots. If there is complex, it has to be complex conjugate that is for any general matrix for a special class of matrices when symmetric λ s are real.

When A is symmetric and positive definite symmetric and positive matrices are called SPDs for symmetry PD for positive different definiteness λ s are real and positive; this means that for a general matrix the for a general matrix the Eigenvalues lie in a complex plane. This is the real axis this is the imaginary axis. So, for a general matrix the Eigenvalue can be anywhere if it is complex, it might occur in conjugate pairs, it could be real, it could be positive, it could be here.

So, that is a general distribution of Eigenvalue for any general matrix for symmetric matrices; the Eigenvalues are always real the Eigenvalues are real this is for symmetric matrix for a positive definite matrix the Eigenvalues are always real and positive. So, you can see the restriction how it can strange the distribution of Eigenvalues, it could be anywhere in the 2 dimensional complex plane for a general matrix. It is along the real line for symmetric matrices it is in the positive half of the real line for symmetric positive definite matrices, we will have lot more occasions to talk about symmetric positive definite matrices.

So, this Eigen structure of symmetric positive different matrices is an important property that we need to keep in mind.

(Refer Slide Time: 04:46)

EXAMPLE OF EIGENVALUES

$$A = \begin{bmatrix} 5 & -2 \\ -2 & 8 \end{bmatrix} \quad \lambda_1 = 9, \lambda_2 = 4$$

- The eigenvector $V_1 = \frac{1}{\sqrt{5}} \begin{pmatrix} -1 \\ 2 \end{pmatrix}$, $V_2 = \frac{1}{\sqrt{5}} \begin{pmatrix} 2 \\ 1 \end{pmatrix}$
 Clearly, $V_1 \perp V_2$
- Let A be SPD and $(\lambda_i, V_i): AV_i = \lambda_i V_i$
- Then $\{V_1, V_2, \dots, V_n\}$ is an orthonormal system
- Let $V = [V_1, V_2, \dots, V_n] \in \mathbb{R}^{n \times n}$, $V^T = V^{-1}$
- Then $AV = V\Lambda$, $\Lambda = \text{Diag}(\lambda_1, \lambda_2, \dots, \lambda_n)$
 $A = V\Lambda V^T$ – Eigendecomposition of A
 $A = \sum_{i=1}^n \lambda_i V_i V_i^T$
- Spectral radius of A = $\rho(A) = \max_i \{|\lambda_i|\}$

$AV_i = \lambda_i V_i$
 $AV_j = \lambda_j V_j$
 $V_1 \perp V_2$
 $AV = V\Lambda$
 $AVV^T = V\Lambda V^T$
 $A = V\Lambda V^T$

We are going to illustrate the computations of Eigen values and Eigenvectors; let A be a symmetric matrix by the previous claim, the Eigenvalues must be real, yes, 9 and 4; they are real, but by solving by solving the equation $AV = \lambda V$, $AV_1 = \lambda_1 V_1$, $V_1^T AV_2 = \lambda_2 V_2^T V_2$, these are 2 equations corresponding to 2 distinct Eigen values. If you solve these linear equations, it can be found that V_1 is one Eigenvector V_2 is another Eigenvector; the Eigenvector, we are interested only in the direction of the Eigenvectors. So, we normalize it. So, V_1 is a normalized Eigen vector V_2 is a normalized Eigen vector it can be shown V_1 is this is not right, it is a perpendicular sign V_1 and V_2 are orthogonal $V_1^T V_2 = 0$ and $V_2^T V_1 = 0$ orthogonal to V_2 orthogonal to V_1 .

So, I would very much encourage the reader to be able to verify these computations. Now I am going to generalize this let a be a symmetric matrix, let $\lambda_i V_i$ be such that $AV_i = \lambda_i V_i$ for each i running from 1 to n, there are n such equations. So, we have a collection of vectors Eigen vectors without loss of generality as you mentioned Eigenvectors are going to be normalized. So, V_1, V_2, \dots, V_n is a collection of mutually orthogonal and normalized Eigen vectors. So, it constitutes an orthonormal system, we have already seen the notion of orthonormality in the last class.

Now, I am going to construct a matrix V which consists of n columns the first column is the first Eigenvector the second column is second Eigenvector and the column is the n th

Eigen vector; this is a matrix there is a correction here, this is the matrix this n by n , this matrix is orthogonal. So, its transpose is equal to inverse. So, from the basic definition AV is equal to $V\lambda$; this essentially tells you simultaneously all the equations that are summarized one for each i . So, this equation AV is equal to $V\lambda$ where λ is the diagonal matrix. So, you can readily see A is the given matrix V is the matrix of n Eigenvectors λ is a diagonal matrix of n corresponding n Eigenvalues look at the order $\lambda_1, \lambda_2, \dots, \lambda_n$ V_1, V_2, \dots, V_n , they are correspondence with each other since V^T is equal to V^{-1} I can multiply on the right side by V^T .

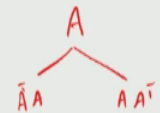

So, $AV = V\lambda$. So, we can multiply $AVV^T = V\lambda V^T$, but VV^T is equal to I identity matrix. So, $A = V\lambda V^T$; this is called the Eigen decomposition of A . This Eigen decomposition of A can be expressed in element form. So, this is simply the sum of the product outer products of V_i and V_i^T . So, $V_i V_i^T$ is a matrix each of these matrices are weighted by λ_i . So, A can be expressed as the weighted sum of rank one matrices each rank one metric corresponds to an Eigen vector the now we come to another important concept associated to this called spectral radius denoted by $\rho(A)$ spectral radius is equal to the maximum of the absolute value of the λ s.

So, if A is a symmetric matrix λ s are real, if A is a symmetric and positive rank λ s are real and positive. So, the spectral radius of a symmetric matrix is given by the maximum of the absolute value of Eigenvalues.

(Refer Slide Time: 09:37)

SINGULAR VALUES OF A

- Let A be non-singular. The Gramians $A^T A$ and $A A^T$ are then symmetric and positive definite.
- Let $(A^T A)V_i = \lambda_i V_i$ with $\lambda_1 \geq \lambda_2 \geq \lambda_3 \dots \geq \lambda_n > 0$
- Verify that $(A A^T)U_i = \lambda_i U_i$ where $U_i = \frac{1}{\sqrt{\lambda_i}} A V_i$
- $A^T A$ and $A A^T$ share the same set of eigenvalues
- Define $\sigma_i = \sqrt{\lambda_i}$ for $1 \leq i \leq n$
- $\{\sigma_i\}$ are the singular values of A

31

Now, we are going to introduce another related concept called singular values of A , let A be a non singular matrix the Gramian A transpose A and AA transpose R , then symmetric positive definite. In fact, there is a result here I would like you to think about the Gramian must be capital G because it is the name of the person capital G .

So, A is non singular A transpose A and AA transpose are symmetric matrix, if A is non singular, it is said to be full rank, if A is non singular and full rank, then AA transpose A transpose A are both symmetric and positive definite this is a very fundamental result with respect to with respect to the symmetric positive definite matrices and its relation to Gramian.

So, if A is non singular A transpose A is symmetric; therefore, I can do a symmetric decomposition Eigenvalue analysis A transpose $A V_i$ is equal to a lambda $I V_i$. This is the same as we have done for A . Now what we did for A , I am redoing for A transpose A here lambda 1, lambda 2, lambda n are the Eigen values because A transpose A is positive that even the least Eigenvalue is positive we are going to order Eigenvalues the largest is called lambda 1. The next largest is called lambda 2 the least largest is called lambda n in the least largest is also positive; that means, everybody else is positive.

Now, I would like to relate the Eigenvalues Eigen vectors of a given a matrix A , there are 2 Gramians A transpose AA ; A transpose both are symmetric and positive definite, I am now going to argue, if you know the Eigenvalues and Eigenvectors of one of the

Gramians; we also can infer the Eigenvalues and Eigen vectors or the other Gramian to that end, I am giving it a homework problem to verify it is very simple $A^T A U_i$ is equal to $\lambda_i U_i$ where U_i is different by $1/\sqrt{\lambda_i}$ from $A V_i$. So, if you, but if I know $A^T A$; if I know $A^T A$ I know λ_i . So, if I know $A^T A$ I know V_i ; I know λ_i . So, using $A V_i$ and λ_i you define a new vector. So, new vector U_i is simply a linear transformation of the vector V_i scaled by $1/\sqrt{\lambda_i}$.

So, this if I define U_i this way, it can be verified that $A^T A U_i$ is equal to $\lambda_i U_i$. So, this essentially tells you λ_i is simultaneously Eigenvalue of $A^T A$ as well as $A A^T$; they both share the same Eigenvalue the Eigenvectors V_i and U_i are related by this. So, here is a summary $A^T A$ and $A A^T$ share the same Eigenvalues and the Eigen vectors are also related you can essentially see U_i is related to the V_i . Now if I define σ_i to be square root of λ_i I know please remember λ_i are Eigenvalues the symmetric positive definite matrix they are all positive. So, square root of that exists and square root of that is real.

So, I am now going to define the positive square root of λ_i equal to σ_i and the σ_i . So, for each λ_i there is a σ_i there are n such σ_i σ_i by definition are called singular values of A . So, the Eigenvalues of $A^T A$ are called the Eigen the square root of the Eigenvalues of $A^T A$ are called the singular values of A . So, singular value decomposition singular values Eigenvalues Eigen decomposition these are all the related concept that we are seeing in this part of the talk.

(Refer Slide Time: 13:49)

MATRIX NORMS

- Let $A \in \mathbb{R}^{n \times n}$. Norm of A is a measure of the size of A
- Frobenius norm of A = $\|A\|_F = \left[\sum_{i,j=1}^n a_{ij}^2 \right]^{1/2}$
- Operator form: (Induced norm)

$$\|A\|_p = \sup_{\|x\|_p \neq 0} \frac{\|Ax\|_p}{\|x\|_p} = \max_{\|x\|_p=1} \|Ax\|_p$$

- Setting $p = 1, 2, \infty$, we get various matrix norms
- Inequalities:
 - $\|Ax\| \leq \|A\| \|x\|$
 - $\|AB\| \leq \|A\| \|B\|$

Now, we move on to another interesting concept relating to matrices just like vectors have a size just like the size of a vector is captured by the notion of a norm of a vector matrix is also an object every object can be endowed with the definition of its size. The size of a vector is measured by the norm of a vector the size of a matrix is also going to be defined by a norm of a matrix. So, I am now going to define the notion of what is called norm of a matrix A, it is the measure of the size of the a just like in the vector case we had various norms 2 norm one norm infinity norm in Kovelsky's norm energy norm; in the case of matrices also we have quite a variety of norms to talk about I am not going to talk about all the possible norms.

I am going to talk about some of the simple norms which are often used in analysis the first of those norms is called the Forbenius norm Forbenius norm of a is simply an extension of the Euclidian norm for the matrix A; the Forbeanius norm is denoted by this symbol the norm sign with a subscript f and what is it you take the sum of the squares of all the elements of the matrix take the square root of it. This is exactly the way we are defined the Euclidean norm. The Euclidean norm of a vector is equal to the square root of the sum of the squares, here it is a square root of the sum other of the squares of all the n square elements in the matrix and that is one measure of the size of the norm there is another norm called induce norm. These induced norm are defined using the notion of an operator.

So, let A be a matrix that corresponds to a linear operator or a linear transformation the p th norm of A is defined by the norm symbol $\|A\|_p$ that is defined by the supremum taken over all x that is not 0 of the ratio $\|Ax\|_p$ divided by $\|x\|_p$. So, you can essentially see the following given a given a pick any arbitrary vector x Ax is a vector computes its p norm x has also its p norm compute this ratio this ratio varies as x varies you vary x ; x belongs to \mathbb{R}^n there are infinitely many x 's as you vary x this ratio varies as this ratio varies, I am interested in the maximum value. So, supremum is like you can think of supreme is a very technical term I do not want to get into the technicality for practical purposes you can assume it is a maximum value of the ratio of the p norm of Ax to the p norm of x .

So, what does this tell to the following a 2 dimensional analogy is like this here the vector x here is the vector fx the fx has. So, the numerator tells you the p th norm of fx the denominator tells you the p th norm of x if this ratio is larger than 1 Ax is larger than x ; that means, there is a magnification if this Ax if the numerator is less than the denominator then there is a shrink.

So, a linear operator can either along need a vector or a shrink vector the maximum of this ratio the magnification factor is called the p th norm of the operator A or a linear transformation A equivalently, we can also compute the p th norm of f where x is constrained by this relation in other words you can consider all those vectors that whose p th norm is 1.

So, you reduce the range of values of n which is which is which is equivalent to this definition. So, this is how you define the p th norm of a matrix by setting p is equal to by setting 1, it should be lower case p by setting p is equal to 1 to infinity, we get various matrix norm, you can get 1 norm 2 norm infinity norm and so on given the matrix. Now that we have a matrix norm, we have a vector norm there are standard inequalities which are of great interest improving several results in analysis. So, then norm of a transformed vector. So, x is a vector Ax is another vector Ax is a transformation of x by A .

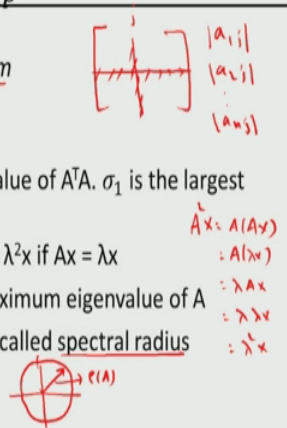

So, what does the left hand sides say in the inequality one the norm of the transformed vector is less than or equal to the product of the norm of the operator A and the norm of the vector x likewise the norm of the product of 2 matrices A and B is less than the product of the norm of the operator A and the operator B these are 2 fundamental

inequalities. Now please realize in this inequality I did not specify the nature of the norm these inequalities true for any and every type of norm you can pick a 2 norm; 1 norm infinity norm or any other norm for all of these norms these inequalities all good these are fundamental inequalities and these inequalities are very similar to several inequalities we have seen for the vectors.

(Refer Slide Time: 19:44)

COMPUTATION OF $\|A\|_p$

- 1) $\|A\|_1 = \max_j \left\{ \sum_{i=1}^n |a_{ij}| \right\}$ - Column norm
- 2) $\|A\|_\infty = \max_i \left\{ \sum_{j=1}^n |a_{ij}| \right\}$ - Row norm
- 3) $\|A\|_2 = \sigma_1$ where σ_1^2 is ^{THE} ~~one~~ max eigenvalue of $A^T A$. σ_1 is the largest singular value of A
- 4) When A is symmetric, $A^T A = A^2$ and $A^2 x = \lambda^2 x$ if $Ax = \lambda x$
 Therefore, $\|A\|_2 = |\lambda_{\max}|$, λ_{\max} = maximum eigenvalue of A
- 5) For A symmetric: $\rho(A) = \|A\|_2 = |\lambda_{\max}|$, called spectral radius

$Ax = A(Ax)$
 $= \lambda(Ax)$
 $= \lambda \lambda x$
 $= \lambda^2 x$

Now, we have defined the norm, but the whole question is how do I compute these p norms how do you compute in other words; how do I compute these various norms for matrices here is an example of the computation if a is matrix the one norm of a it can be proven that is equal to the maximum over j of summation i equals one turn a i j. So, let us talk about this. Now I have a matrix A i have a matrix AA has different columns. So, let us consider the j th column of a the elements of the j th column are going to be a one j a 2 j and a n j.

So, what is that we are now going to be looking for we are going to be looking for the absolute value of each of these and I am going to take this sum of the absolute value this must be absolute value sum of the absolute value of the elements and take the maximum over j. So, one is called the column norm another is called the row norm. So, the maximum is taken over j for the column norm because j is the column index i is the row index. So, now, look at this now. So, for one you sum along the row and for another one you sum along the column.

So, one is called the first one the one norm is called the column norm the infinity norm is called the row norm. It can be shown that one norm can be easily computed by this infinity norm can be easily computed by this these are computational algorithms for quantifying the values of these norms the 2 norm of a matrix is where it can be simply stated as σ_1 where σ_1^2 is the maximum Eigenvalue this must be the maximum Eigenvalue the maximum Eigenvalue of $A^T A$ σ_1 is also called the largest singular value we simply introduce the notion of a singular value in the last couple of slides.

So, given A ; you compute $A^T A$ $A^T A$ is symmetric and positive definite if A is non singular; it is symmetric and positive definite. So, all the Eigenvalues are real and positive the square root of these Eigenvalues are called the singular values, the maximum of those singular values; it is called the 2 norm of A call the 2 norm of A when A is symmetric; it transposes the A .

So, $A^T A$ is a square x is equal to $\lambda^2 x$ of A is equal to λx what is that x is equal to A times A of x this is A times λ of x this is equal to λ times A of x there is equal to λ times λ of x that is equal to λ^2 of x therefore, if λ is an Eigenvalue of A λ^2 is an Eigenvalue of $A^T A$.

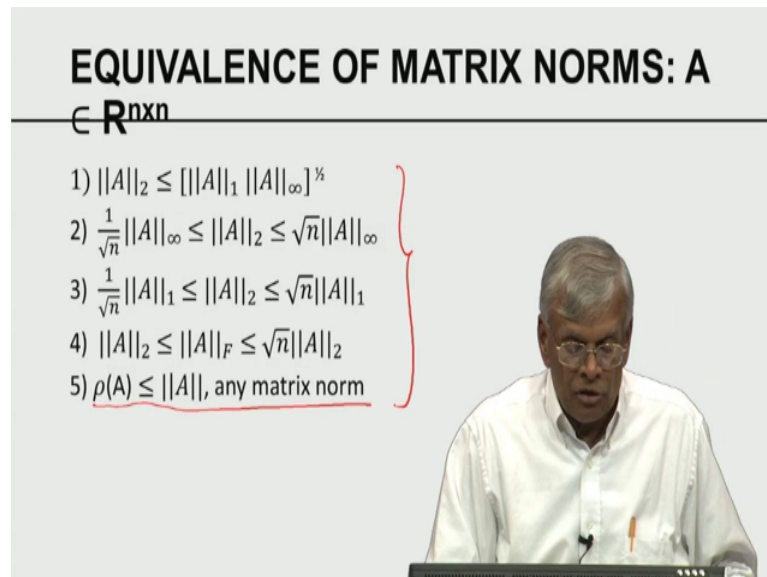

If λ is an Eigenvalue λ^k is Eigenvalue of A to the power k . So, that is how the Eigenvalue square itself when you square the matrices therefore, by combining 3 and 4 we can see the 2 norm of A is simply the maximum of the Eigenvalue I do not have to even put the absolute value sign because $A^T A$ is positive symmetric and positive definite.

So, σ_1 is always positive, but for safety sake one can introduce with our loss of generality and λ is the maximum Eigenvalue and we can also recall that the maximum Eigenvalue is called the spectral radius. Therefore, we can conclude the 2 norm of a symmetric positive definite matrix or asymmetric positive definite matrix is given by the spectral radius.

So, what is it what a spectral radius means if you consider a circle with centre or origin and diameter as I am sorry that the radius as ρ of A all the Eigenvalues of the matrix A lie within that circle.

So, that is the notion of the spectral radius of this matrix A. So, we talked about matrices there are norms; we have studied various properties of norms these are the computational procedures for computing the values of different norms of interest in analysis.

(Refer Slide Time: 24:36)

EQUIVALENCE OF MATRIX NORMS: A
 $\in \mathbb{R}^{n \times n}$

- 1) $\|A\|_2 \leq [\|A\|_1 \|A\|_\infty]^{1/2}$
- 2) $\frac{1}{\sqrt{n}} \|A\|_\infty \leq \|A\|_2 \leq \sqrt{n} \|A\|_\infty$
- 3) $\frac{1}{\sqrt{n}} \|A\|_1 \leq \|A\|_2 \leq \sqrt{n} \|A\|_1$
- 4) $\|A\|_2 \leq \|A\|_F \leq \sqrt{n} \|A\|_2$
- 5) $\rho(A) \leq \|A\|$, any matrix norm

Just like we had talked about equivalence between the one norm 2 norm infinity norm for vectors here also, I have a set of inequalities that relate to the behaviour of various norms. So, you can show given a matrix A the 2 norm is less than or equal to the product of the square root of the product of one norm and infinity norm.

The infinity norm and the 2 norm, I can sandwich the 2 norm using the infinity norm I can sandwich the 2 norm by one norm, I can sandwich the Forbenius norm by 2 norm, we also know that another result which is a fundamental important the spectral radius is less than I am sorry the spectral radius the spectral radius, I want to highlight this the spectral radius of a matrix is less than any matrix norm equality happens when the metric system is a symmetric.

So, these are some of the interrelations between the 2 norm the one norm the infinity norm the Forbenius norm of matrices in the case of matrices. In the case of matrices, the Eigenvalues play definitely role in the definition of norms especially for the 2 norm and this is a very nice summary of the various properties of norms of matrices.

(Refer Slide Time: 26:06)

CONDITION NUMBER OF A MATRIX

- Let $A \in \mathbb{R}^{n \times n}$.
- Condition number $\mathcal{K}_p(A) = \|A\|_p \|A^{-1}\|_p$ and its value is norm dependent
- Since $I = AA^{-1} \Rightarrow 1 = \|I\|_p \leq \|A\|_p \|A^{-1}\|_p = \mathcal{K}(A)$
- Thus, $1 \leq \mathcal{K}(A) \leq \infty$
- Spectral condition number of symmetric matrix A

$$\mathcal{K}_2(A) = \|A\|_2 \|A^{-1}\|_2 = \frac{|\lambda_{\max}|}{|\lambda_{\min}|}$$

$Ax = b$
 \uparrow
 $L = AA^{-1}$
 $1 = \|I\|_2 \leq \|A\|_2 \|A^{-1}\|_2$
 $10^3 < 10^6 < 10^9$
- Spectral condition number of A non-singular

$$\mathcal{K}_2(A) = \|A\|_2 \|A^{-1}\|_2 = \frac{\sigma_1}{\sigma_n} = \frac{\sigma_{\max}}{\sigma_{\min}}$$

$A \quad \lambda$
 $A^{-1} \quad \lambda^{-1}$

σ_i is the i^{th} singular values of A with $\sigma_1 \geq \sigma_2 \geq \dots \geq \sigma_n > 0$

Why do we do norms for 2 reasons one is to be able to measure the size of the norm. Secondly, the notion of 2 norm is very useful in trying to quantify certain properties of matrices we say a matrix is singular we say a matrix is non singular we say a matrix is well conditioned we say a matrix is ill conditioned one of the conditions for the solution of Ax is equal to b , we all know if I want to be able to solve Ax is equal to b , we would like to be able to make sure A is non-singular.

We also know when. So, we have singular and non singular yes or no day and night, but in practice some matrices may be very close to being singular without being singular. So, such matrices are said to be ill conditioned. So, I need to be able to characterize the degree of non singularity how do you measure the degree of non singularity one way to be able to measure the degree of non singularity is through the notion of what is called a condition number of a matrix.

So, let A be n by n matrix this is the definition the condition number of a matrix is denoted by the symbol kappa of A the condition number is dependent on the definition of norm. So, this is the condition number using p norm of a matrix the condition number of A p norm of a matrix is simply the product of the p norm of A times the p norm of A inverse.

Therefore you can see the definition of the condition number is non independent. So, I can have norm one conditioning norm 2 conditioning norm infinity conditioning so on

and so forth; this in general if you cannot solve the equation $Ax = b$, we throw the word or the matrix is ill conditioned. So, if something is ill conditioned then there must be a concept of well conditioned is something is singular non singular very nearly singular, these are all fuzzy characterizations of properties of matrices we would like to be able to quantify this fuzziness using certain measure of the properties of these matrices that is where the condition number comes into play; how the condition number is related to the well conditioning ill condition of the matrices that is what we are going to be talk talking about presently recall the standard identity $I = AA^{-1}$ the p norm of I is one for every p 1 to infinity.

So, by, but we know. So, if I is equal to AA^{-1} ; if I took the norm of I the norm of I , it must be less than or equal to norm of A times norm of A^{-1} this is inequality that we saw in couple of pre slide the 3 slides, but the norm of identity matrix is 1; therefore, I get this inequality one is less than the product of the p norm of A and A^{-1} A^{-1} inverse by this definition the product of A and A^{-1} is the condition number. So, you can readily see the condition number of A is always greater than equal to 1 is always greater than equal to one. So, condition number is greater than equal to one condition and that is a positive number it can be very large. So, the range of the values of the condition number is one to infinity

So, in this scale when the condition number is closer to one we say it is well conditioned when the condition number is very large is ill conditioned again how large is large we will talk about that in a minute; how large is large depends on the computer machine position in a thirty bit the arithmetic well that is only a largest value you can measure therefore, if a condition number κ of a matrix; let us say is 10^{20} or 10^{50} a matrix A 10^{50} is said to be more real conditioned than a matrix is 10^{20} which is more real condition than a matrix with 10^3 .

So, this ranking of the of the condition number helps you to in some sense quantify the degree of ill condition associated with the matrix . So, now, let us; I used the p norm, I am now going to specialize the discussion of the norm for a spectral condition number. So, let A be a symmetric matrix spectral condition number is related to the maximum Eigenvalue we also know the following if λ is an Eigenvalue of A λ^{-1} is the Eigen value of A^{-1} therefore, the 2 norm of A is the maximum Eigenvalue of A

the 2 norm of a inverse is the minimum Eigen value of A. So, condition number for symmetric matrices is simply given by the ratio of the maximum Eigenvalue to the minimum Eigenvalues.

Therefore the spectral condition number so, for a symmetric matrix this for a general non symmetric, but non singular matrices the condition number is simply given by σ_1 by σ_n where σ_1 is the largest I am sorry this must be σ_n sorry this means be σ_n , this is the ratio of the largest to the smallest singular values where σ_i is the i th the singular value and σ the signal values are counted like σ_1 one is greater than equal to σ_2 there than equal to σ_n and σ_n is positive.

Now, for this slide provides you a new a concept of associating a number with the matrix called the condition number the value of the condition number is very indicative of the difficulties that one will have in computational process.

(Refer Slide Time: 32:57)

RELATION BETWEEN CONDITION NUMBERS

1. $\frac{1}{n} \mathcal{K}_2(A) \leq \mathcal{K}_1(A) \leq n \mathcal{K}_2(A)$
2. $\frac{1}{n} \mathcal{K}_\infty(A) \leq \mathcal{K}_2(A) \leq n \mathcal{K}_\infty(A)$
3. $\frac{1}{n^2} \mathcal{K}_1(A) \leq \mathcal{K}_\infty(A) \leq n^2 \mathcal{K}_1(A)$

Note: Since $\|A\|_1$ and $\|A\|_\infty$ norms are easily computed, we can estimate $\mathcal{K}_2(A)$ using the above relations.

Before going further I also want to be able to relate the various properties of condition numbers again matrices are related the Eigenvalues the matrices these singular values are related the norms are related they. So, there is a relation between all the condition numbers themselves because condition numbers are defined in terms of norms.

If norms are related if condition numbers are related to norms condition numbers also must whole certain relations among themselves. So, the 2 condition number one

condition number infinity condition number and 2 condition number infinity condition number and one condition number you can say they are all interposed. So, what does this mean if a matrix is well conditioned in one norm, it is well conditioned in every norm if a matrix is ill conditioned one norm, it is ill condition in every norm. So, what does this tell you can pick any now that suits you computationally and do the analysis without having to worry about the choice of the norms? So, that gives you provides that provides you a lot of freedom.

But among all the norms or the one norm and infinity norm are is very easily computed when is the column norm another the row. Now, therefore, from a computational perspective one may want to be able to use one norm or infinity norm, but in mathematical analysis theoretical analysis, they generally often use the 2 condition number 2 now because 2 condition about 2 norm is intimately associated with the Eigen structure spectral radius and so on that is a very appealing very appealing property.

RELATION BETWEEN $\det(A)$ AND $\mathcal{K}(A)$

- Let $A = \text{Diag}(\frac{1}{2}, \frac{1}{2}, \dots, \frac{1}{2})$

$$\Rightarrow \det(A) = \frac{1}{2^n} \rightarrow 0 \text{ as } n \rightarrow \infty$$

$$\Rightarrow \mathcal{K}_p(A) = 1 \text{ for } p = 1, 2, \infty$$
- Let $B \in \mathbb{R}^{n \times n}$, upper triangular:
$$a_{ij} = \begin{cases} 1 & \text{if } i = j \\ -1 & \text{if } i > j \\ 0 & \text{if } i < j \end{cases}$$
- $\det(B) = 1$ and $\mathcal{K}_\infty(A) = n \rightarrow \infty$ as $n \rightarrow \infty$
- Thus, there is no correlation between $\det(A)$ and $\mathcal{K}(A)$

$Ax = b$
 $|A|$

37

In the first course, in linear algebra, we are generally told the ill condition of the matrix is decided by the value of the determinant, but I am going to give you a counter example to show, it is not the case in other words what we are told in a first course in linear algebra if I have difficulty in solving Ax is equal to b if I am; if I have difficulty in solving Ax is equal to b if the determinant of a is very large or very small then they will simply tell that that you will have numerical difficulty yes you may have numerical

difficulty, but the ill conditioning of a matrix is not determined by the determinant of a matrix as might often be given to understand in the first course.

So, here there are a couple of very good examples let a be a diagonal matrix of all halves the determinant of a is $1/2^n$ you can readily see the determinant of a goes to 0 as n goes to infinity, but the condition number of a is one for all n . So, the determinant and condition number they do not have much of a relationship as another example let b be a n by n matrix consider an upper triangular matrix given by this we can readily see the determinant of b is one, but the condition number of b is n and goes to infinity as n goes to infinity.

So, what does it mean I can have matrices where the determinant goes to 0, but the condition number remains constant I can have matrices where the determinant remains constant, but the condition number can go to infinity.

So, this essentially tells you there is no intrinsic correlation between determinants and condition number even though we simply say a matrix must be non-singular; that means, the determinant should not vanish for being able to solve $Ax = b$ is equal to b the appropriate way to describe the properties of solution one obtains from solving a linear equation one has to relate it to the condition number of A . So, κ is much more important than the determinant why κ is more important.

SENSITIVITY OF SOLUTION OF LINEAR SYSTEM

- Let $Ax = b$ be the given system.
- Let $(A + \epsilon B)y = (b + \epsilon f)$ be the perturbed system
- ϵB and ϵf are the perturbation and the vector respectively, and $\epsilon > 0$ but small
- The relative error in the solution is given

$$\frac{\|y - x\|}{\|x\|} \leq \kappa(A) \left[\epsilon \frac{\|B\|}{\|A\|} + \epsilon \frac{\|f\|}{\|b\|} \right]$$
 $\kappa = 10^6$
- Since $\kappa(A) \geq 1$, the errors in A and b are amplified in the solution
- Larger $\kappa(A)$ is, more sensitive the system is to round-off error in A and b

Now, I am going to give you another result that will force the importance of kappa the condition number within the context of solving linear systems; let us suppose I want to solve $Ax = b$.

Now, let us think of the possible way suppose you want to enter the number $1/3$ and you press the key $1/3$. So, $1/3$ is supposed to be stored in your machine, but $1/3$ can never be stored correctly its point 333 ; what is the problem $1/3$ does not have a terminating decimal expansion only numbers that have terminating decimal expansion will be able to one can hope to be able to represent them correctly.

So, $1/3$, $1/7$; these numbers once you store them to start with there is an error only rational numbers have terminating fraction a rational a general real numbers may not have terminating fraction when you do arithmetic you cannot confine yourself simply to rational arithmetic we are supposed to have real arithmetic. So, when you try to store a real number in a finite precision machine there is always error in representation; that means, you start with your left foot.

So, when you think you have solving $Ax = b$ you are not actually solving $Ax = b$ you are solving $Ax = b + \epsilon$. So, what does it mean the ϵ in the matrix A is the error in A the ϵ in b is the error in b there are 2 kinds of errors A may be obtained from experimental that that could be an inherent error in the experimental measurements A the number is told them storage error. So, ϵ in this case I am simply I am not worrying about other errors that arise out of finite precision arithmetic.

So, ϵ in A ; A is the matrix the ϵ is a small number. So, if I am thinking I am storing A ; you are not storing A you actually are storing $A + \epsilon$, you do not know what ϵ is, but you know that there is an error ϵ is likewise an error. So, why is the system; you are solved; why is the solution system you are solving and you are pretending why is x this is the game we all play, that is nature of business. So, ϵ in A and ϵ in b are the perturbations of the matrix and the vectors respectively.

But we are ϵ is greater than 0, but small. So, if y is not equal to x there is an error I am not going to consider the relative error in y . So, y is a vector x is the true solution $y - x$ is the error vector in the solution I am going to take the norm of the error divided by the norm of the true solution. So, what is that call the left hand side is called

they are real I am sorry relative error in the computed solution I am not going to show the derivation the derivation I generally do it in my class, but it you take us too much into the outside of this scope of these lectures it can be shown that this relative error is bounded about by the product of condition number times the epsilon divided f times b by a plus epsilon times f by b.

Now, let us talk about b what is b? B is the error matrix that corrupts AA is the real matrix. So, this is the relative error in a; this is the relative error in b epsilons are the are the multiplying factors the same epsilon in here. So, the right hand side is the constant multiple of epsilon times the sum of the relative errors in the matrix and on the right hand side now the computer precision decides what b is the computer precision decide what f is epsilon is decided by the smallest value of the computer can store.

So, all these factors are decided by the computer architecture who depends. So, what else. So, your relative error is bounded by can be magnified by the product kappa a times the some other relative errors. So, if kappa is large your solution could be much more erroneous your know kappa by a small your solution could be much more precise therefore, this is the reason why we call kappa the condition number it is a conditioning the matrix that relates to the quality of the solution obtained by any method that you use to solve $Ax = b$ now what is any method I saw what are the methods we know how to solve $Ax = b$ being a ton of methods no matter whatever than a third you use this you are you are bound by the inequality.

So, if kappa is. So, if kappa is 10 to the power of twenty means why you a relative error can go up to 10 to the power of twenty if the relative error can go up by twenty power of twenty what does it mean you have spent the money, but the result is not what the paper written it. So, that is the importance of the notion of condition number why is this important people in meteorology will say I am using a 3 D-VAR I am using a 4 D-VAR, I am using this I am using that yes all those algorithms are very well understood very well known, but you need to be cognizant to the fact that the solution that these algorithm output the quality of it is decided by the nature and properties of the matrix that go into the computational process. So, since kappa is greater than one errors in a and b are amplified.

So, this is the keyword amplified the larger kappa more sensitive the system to the round of errors round of errors comes because of finite precision arithmetic. So, how. So, here is a beautiful idea. Now I have a problem to solve, I have an algorithm to solve the problem I have a computer architecture on which the algorithm is implemented here we talk about the effect of computer architecture the finite precision arithmetic could have on the quality of the solution that you are going to put. So, it is a beautiful combination of algorithms and architecture how they are melded together to give a solution whose quality can be quantified like this.

Exercise

- 3.1) Give an examples of A and B where $AB \neq BA$ and $AB = BA$
- 3.2) Verify $(AB)^T = B^T A^T$
- 3.3) Verify $\text{tr}(AB) = \text{tr}(BA)$
- 3.4) Prove $\det(A^{-1}) = \frac{1}{\det(A)}$ (Hint: $AA^{-1} = I$)
- 3.5) Verify $A = \begin{bmatrix} \cos\theta & \sin\theta \\ -\sin\theta & \cos\theta \end{bmatrix}$ is an orthogonal matrix
Plot $y = Ax$ when $x = (1, 1)$ for $\theta = 30^\circ, 60^\circ, 90^\circ, 120^\circ, 150^\circ$
- 3.6) Verify $(AB)^{-1} = B^{-1}A^{-1}$
- 3.7) Verify $A^+ = (A^T A)^{-1} A^T$ and $A^+ = A^T (AA^T)^{-1}$ satisfy the definition of the generalized/ Moore – Penrose inverse

39

With that we end the coverage of review of matrices I am going to suggest several exercises and they are given in these problems.

(Refer Slide Time: 44:01)

Exercise

3.8) Find the range and kernel of

$$A = \begin{bmatrix} 1 & 3 \\ 2 & 2 \\ 3 & 1 \end{bmatrix}$$

3.9) Verify $(AB)^* = B^*A^*$ and $(A^{-1})^* = (A^*)^{-1}$ where recall that A^* is the adjoint of A

3.10) If $AV = \lambda V$, then $A^2V = \lambda^2V$ and $A^kV = \lambda^kV$

3.11) If A is non singular, then A^TA and AA^T are SPD

3.12) If $(A^TA)V_i = \lambda_i V_i$ and $u_i = \frac{1}{\sqrt{\lambda_i}} AV_i$, verify that $(AA^T)u_i = \lambda_i u_i$

40

There are about twelve problems in here and I will strongly encourage students to use pencil paper work do not go; do not write a program you should know it first to be able to do with hand before you do with computers. So, all these problems are very simple and fundamental to understanding many of the concept will be cover.

If you want proves of many of the things that we have done in this lecture you can refer to the 3 times standard textbooks these are my favourite one Golub and Van Loan Meyer Horn and Johnson. So, with this we conclude our coverage of overview of many results

from matrices you can see we have reviewed a ton of results you may wonder do we need all of them you will soon see, we will use almost all of them in our analysis of algorithms expressions.

Thank you.
