Lecture - 24
Tournament Problem

Welcome back. So, we have been looking problems and how to solve them by using graph theory and induction and various other proof techniques that we have learned so far.

(Refer Slide Time: 00:15)

Problem: Handshake problem

Let $n > 1$ be an integer. In a football league there are n teams. Every two teams have played against each other exactly once, and in match no draw is allowed. Prove that it is possible to number the teams in such a way that team i beats $(i + 1)$ for $i = 1, 2, \dots, n - 1$.

Discrete Mathematics Lecture 24: Tournament Problem

So, in this video lecture, we will be looking at this problem that we had discussed couple of videos ago. So, it says that in a football team there are n teams. Every two team has played with each other exactly once and there is no match indefinite draw. So, either of one of the team must have won. Prove that it is possible to number fifteen in such a way that team i with $i + 1$ for i equal to 1 to n minus 1.

(Refer Slide Time: 00:03)

Graphs

- Vertices - set of elements.

$$V = \{v_1, \dots, v_n\}$$

- Edges - set of pairs of vertices.

$$E = \{e_1, \dots, e_m\}$$

$$e_k = (v_i, v_j)$$

- Given the set of vertices and edges we have a graph

$$G = (V, E)$$

Now to solve this problem we would first like to use graph theory to model this problem and that would help us to solve it, visualize the problem. So, quick recap of graph theory. So, we have vertices and we have edges which are pairs of vertices and this constitutes of graph. The graph is give as the set of vertices and set of edges. Now, there are some basic definitions that are there and they are.

(Refer Slide Time: 01:39)

Basic Definitions

- Let $G = (V, E)$ be a graph.
- If $(u, v) \in E$ implies $(v, u) \in E$ then it is called an undirected graph.
- An weight can be assigned to each edge. In that case it is called an weighted graph.

So, if u and v is in the edge implies v as u in the edge in other words that relationship is reflected we call it an undirected graph. Sometimes weights are assigned to the edges and in that case is a weighted graph.

(Refer Slide Time: 02:10)

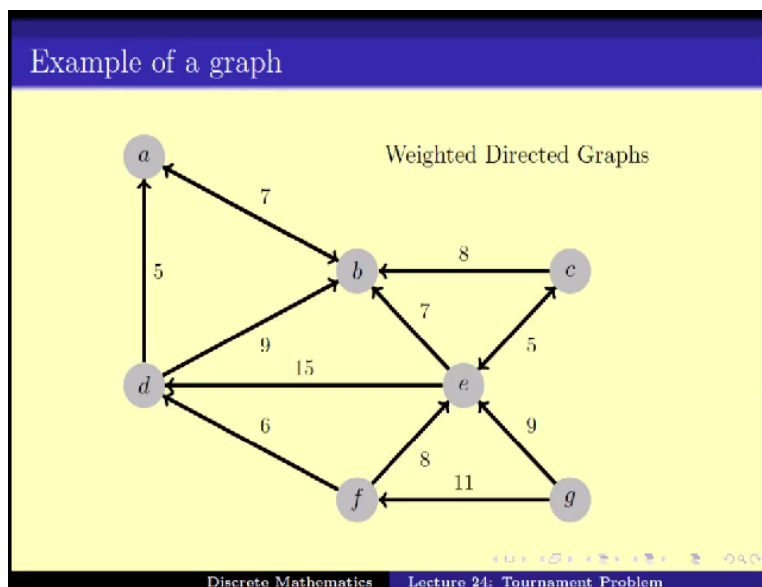

Basic Definitions

- Let $G = (V, E)$ be a graph.
- If there is an edge from vertex u to v we say v is a neighbor of u .
- For an undirected graph the total number of u such that $(u, v) \in E$ is called degree of v .

Discrete Mathematics Lecture 24: Tournament Problem

If there is edge between u to v we say v is neighbor of u and in an undirected graph the degree of v is the total number of edges that is going out of u now v .

(Refer Slide Time: 02:31)

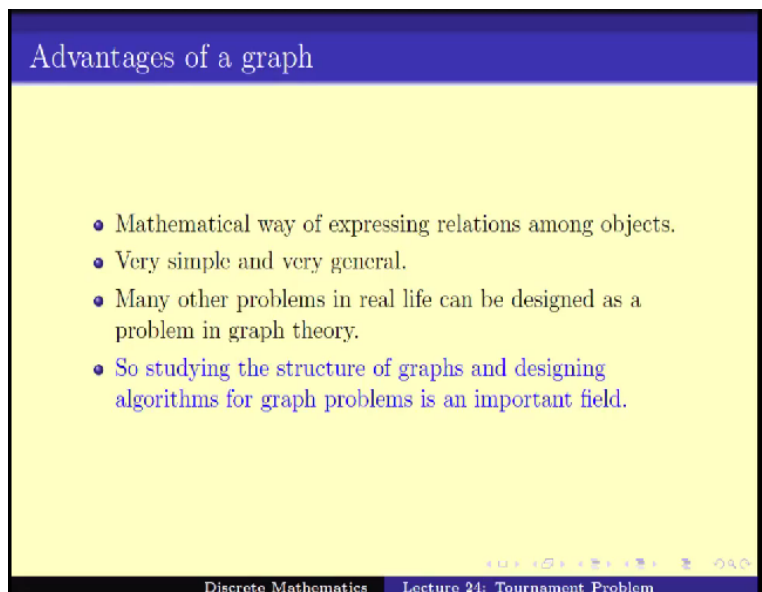

So pictorially we represent the graph as it is blocks so here the vertices are a, b, c, d, e, f and g and we can denote the edges or the relations by lines drawn from one block to the other So here for example this gives us the graph the edges are drawn between a and b , a and p , b and p and so on. There is no edge between a and c which means that a and c are not related. It is binary relation. Now there can be edges away from the edges and in that case, we call it weighted

undirected graph and sometimes edges need not be undirected in the sense that d to a , and a to d might be different.

In that case, we get directed graph and if you notice using this arrow. So the arrow says that there is a graph, there is edge from d to a . This arrow is the arrow in both sides it means that there is edge from a to b and that edge from b to a . So, this helps us to represent graph or binary relations which are not reflexive.

(Refer Slide Time: 04:20)

Now, there are various advantage of using a graph namely the graph are very simple objects and that they are very simple and very general. So, many problems in real life can be designed as problems in graph theory. So, starting the structure of graph and designing the algorithm for graph is an important field and hence studying graph in general with various properties can be a way of coming up with a uniform way of assessing various set of problems.

In this video, we will be looking at some more properties of graph or structure of graph that we will be studying.

(Refer Slide Time: 05:07)

Introduction to Graph Theory

There are a number of properties/structures in graphs that keeps of arising again and again. We we have special names for theses.

Paths: Given a graph $G = (V, E)$ a path from u to v ($u, v \in V$) is a sequence of vertices v_0, v_1, \dots, v_k such that $v_0 = u$, $v_k = v$ and for all $0 \leq i \leq (k - 1)$ the edges (v_i, v_{i+1}) is in E .

Discrete Mathematics Lecture 24: Tournament Problem

So, as an introduction of graph theory there are various properties and structure that keep arising again and again. We have special names for this kind of structure or property and you would like to study them. So here is one of them it is called the path. So, given a graph a path from u to v is a sequence of vertices v_0 to v_k , k can be any number such that first one is u the last one is v and for all edges the edge demark edge from v_i to v_{i+1} or v_i from the v_{i+1} is an edge should be edge second. So this is called a path.

(Refer Slide Time: 06:13)

Paths

Directed Path from g to a

Discrete Mathematics Lecture 24: Tournament Problem

So, let's quickly see some example so if this is a graph and I want to see whether there is a path from g to a . So, this is a path there is path in the sense that I can go from g to f , from f to d and

from d to a. So, in this case the path that we ride is g, f, d, a. So, this is v_0 . This is v_1 . This is v_2 and this is v_3 . As you can see v_0 equal to g, v_3 is a and there is an edge between v_0 and v_1 . There is an edge between v_1 and v_2 which is an f and d and there is an edge between v_2 and v_3 which is d x a.

There can be many paths of g to a. For example, this is a path, where as I can also have this path g to e, e to b and b to a is also a path from g to a. So, g e b a is a path from g to a. Similarly, this is another path from g to a, somewhat more coagulated path g e c b d a. Now, if graph is a under a is directed for example if this is a direct that I have denoted by the arrows then this is not a path from g to a. Why?

Because this a d to b is going to the opposite direction. If I have to go from g to a, then I have to go from g to e, e to c, c to b but I cannot go from b to d with edge is going in other direction. So, one good way of thinking about graph as if these are city and they are road connecting the city and there are roads on one way sometimes or maybe you can think of flight. There are flights from g to e. There is a flight from d to b but there is no flight from b to d.

But when we are asking from path from g to a it is basically saying can I go from if city is g to city a, by using a sequence of flights. But this is not a valid thing valid path from g to a. But I would like you to fly from g to e. I will be able to fly from e to c. I would limit to fly from c to b. But I cannot fly from b to d. This edge is in the opposite direction but we can come up with another path from g to a namely this one. And then we get a path from g to a.

(Refer Slide Time: 09:23)

Connectivity

We say " u is connected to v " if there is a path from u to v .

An undirected graph is called connected if for every vertices u and v there is a path from u to v .

In an undirected graph if there is path from u to v there is a path from v to u .

Discrete Mathematics Lecture 24: Tournament Problem

Now, this also helps us defining the next big concept which is called connectivity, we say u is connected to v if there is a path from u to v if the graph is directed it means the directed from u to v . In an undirected graph since there is no one-way direction you can see for yourself that if there is path from u to v then there is path from v to u and if a graph any two vertices can be reached from one to the another then we call that graph a connected graph.

So, in another words the graph connected if I can go from any vertex to any other vertex may be through some direct complicated $(())$ (10:27). If something like you have a set of cities in India and there are flight networks that goes across the cities. Is it possible to go from any city in India to any other city in India using flights? And if it is so then we call it a connected network or a connected graph.

(Refer Slide Time: 10:54)

Problems on Paths

Given any graph G prove that the relation " u is connected to v " is an equivalent relation.

⏪ ⏩ ⏴ ⏵ 🔍 🔄

Discrete Mathematics Lecture 24: Tournament Problem

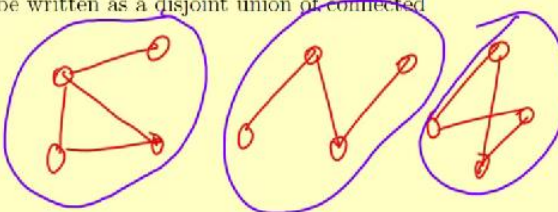

So, one problem that I would like to assign you is that prove that the relation u is connected to v is an equivalent relation. If we have to look at equivalent relation, means our first week and it is relation that means u is related to v if u is connected to v . They prove that it is equivalent relation.

(Refer Slide Time: 11:28)

Connected Components

In an undirected graph the set of vertices connected to a vertex u is called the connected component of u in the graph.

A graph can be written as a disjoint union of connected components.

⏪ ⏩ ⏴ ⏵ 🔍 🔄

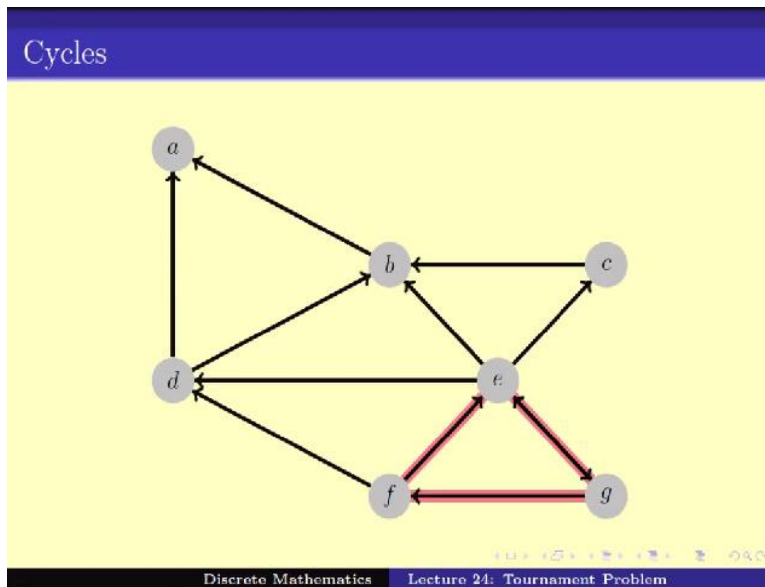

Discrete Mathematics Lecture 24: Tournament Problem

So, moving on once you have equivalent relation it is not hard to prove from the definition or from the properties of equivalent relation that the whole graph will split into equivalent classes we call them the connective components. So, connected components of a graph is the component where any two vertices are connected. The graph can be written as a disjoint union of connected

components. For example, if I have a graph like this note that the connected component if this is the whole graph and the connect components are this is one connect component.

This is the other connect component and this is the other connected component. There are three connected components here.

(Refer Slide Time: 12:53)

Now sometimes we can have paths that end up in itself so then we call it as cycle. For example, this is a cycle. I can start from b I can go to a, d I go to f. I go to c, go to e and come back to d. So, cycle is a collection of edges that bring me back to my starting vertex. So, that is called a cycle. In an undirected graph again, we do not have to vary all direction of the edges but when the graph are directed then we have to worry about it. So this is another cycle that is there a b, d e but once we put the edges there we see that this is not exactly a directed cycle.

Why? Because I can start with e go to b if this is fine, b to a but I cannot go from a to d, neither can I go in the opposite direction. For example, I cannot start e and go into d first. So, irrespective of which way I go, I cannot come back to my place following the set of edges. So, this is not a cycle but this one is a cycle, direct cycle. Why? I can go from g to f, f to e and e to g because a, d to g exists. So this is a directed cycle.

(Refer Slide Time: 14:39)

Trees

- A directed graph that has no cycle is called an **acyclic graph**.
- A connected undirected graph that does not have a cycle is called a **tree**.

Discrete Mathematics Lecture 24: Tournament Problem

So, if a directed graph does not have a cycle because it has acyclic graph and in a connected under acyclic graph that has no cycle we call it a tree. This is a very important concept we will come back to this concept again and again in this next few videos. Trees are very important objects they are undirected acyclic graph or undirected graph that do not have a cycle.

(Refer Slide Time: 15:16)

Trees

- A connected undirected graph that does not have a cycle is called a **tree**.
- A tree that touches every vertex is called a **spanning tree**.

Discrete Mathematics Lecture 24: Tournament Problem

For example, here in this graph this is a tree, set of red edges forms a tree. Note, that by looking at the red edges, red edges were only part of the graph if there was not any cycle. So, red edges do not form a cycle at all. So, this is a tree. We can have many trees. This is another tree. So, I mean that the red edges are the tree edges. So, connected under the graph that does not have a

cycle is called a tree. A tree that touches every vertex is called a spanning tree just like in this case.

If the original graph is this whole graph and its red edges form a tree, note that it touches every vertex in this graph. So, this is a spanning tree. Now, there are few problems that I would like you guys to think about; we will come back next week to solve many of the problems.

(Refer Slide Time: 16:25)

The slide is titled "Problems on Trees" and contains the following content:

- Problem**
How many edges are there in a tree on n vertices.
- Definition**
If $G = (V, E)$ is a graph then $H = (V', E')$ is a subgraph of G if $V' \subset V$ and $E' \subset E$.
- Problem**
Does every graph have a spanning tree as a subgraph. .

At the bottom of the slide, it says "Discrete Mathematics" and "Lecture 24: Tournament Problem".

First of all, how many edges are there in a tree on n vertices? Can you give me a number and secondly just like you have been talking about this spanning tree or the example if G is a graph and H is another graph we call H is a subgraph of G if the vertex set is the subset of the original vertex set and edges set and H is a subset of E set in G . So, in other words if I give you a G and if I remove some of the edges till I get a subgraph of G .

A question is that does every graph have a spanning tree as a subgraph. So, this is a quick introduction to graph theory.

(Refer Slide Time: 17:28)

Modeling the problem

- Let the vertices be the teams. So there are ~~2n~~ⁿ vertices v_1, \dots, v_n
- There is an edge from v_i to v_j if the team v_i defeated v_j .
- So the graph is directed.
- Between any pair of vertices v_i and v_j either there is an edge from v_i to v_j or an edge from v_j to v_i . We call such a graph a **Tournament**.
- Is there a path where every vertex appears exactly once.

And now using this set of graphs that we have learned. A various graph that you have seen can we at least formalize this statement of this problem? So, here again there are n teams. Any two teams play with each other one of them win other one loses, prove that it is possible to number the teams in such a way that the team i repeats team $i + 1$. So, to formalize as a graph theory problem you have to first set up the graph. So, of course let there be n teams.

So, this is not n , this will be just not $2n$ but just n . There are n teams so let the n vertices be v_1 to v_n and we draw edge from v_i to v_j if v_i defeated the team v_j . If v_i defeated v_j it does not implies v_j defeated v_i . So in fact the graph is directed. So, here it is not an undirected graph but we have a directed graph and more over with the any two pair since they have played with each other v_i and v_j there must be an edge and there must be exactly one edge meaning there is edge either to v_i and v_j or edge from v_j to v_i not both.

Such a graph is called a Tournament. A tournament is a graph where between any two vertices there is an edge but edge is oriented or in another words the edge is either in one direction or the other not (()) (19:26). Question is that, is there a path where every vertex appears exactly once. Now, why is it the right question?

(Refer Slide Time: 19:41)

Hamiltonina Path

For any graph $G = (V, E)$ a Hamiltonian Path is a path that touches every vertices exactly once.

Before, I could assign the value to be in path. Let me quickly try to understand is an example of it. So, say I have this team. So, here are four teams A B C D and say A has defeated B, C has defeated A, B has defeated C, D has defeated C. But D has been defeated by A and B has been defeated by D. So, this is arbitrary graph of a tournament. Now, what do I mean by, what do I have to do? I have to order them in such a way that the i team defeats the $i + 1$ team.

So, in this particular graph think of this way that if I numbered D to be equals to 1, B to be number 2, c to be number 3 and A to number 4. What do I have? I get DB CA and note that D repeated B because of the edge, B defeated C because of the edge again and C defeated A. So, I get a path here like this where every edge, every vertex is coming once. So, this is what I have to get. So, I have to get a path like this which touches every vertex, exactly want.

Such kind of an edge or such kind of path is called a Hamiltonian Path.

(Refer Slide Time: 22:01)

Modeling the problem

- Let the vertices be the teams. So there are $2n$ vertices v_1, \dots, v_n .
- There is an edge from v_i to v_j if the team v_i defeated v_j .
- So the graph is directed.
- Between any pair of vertices v_i and v_j either there is an edge from v_i to v_j or an edge from v_j to v_i . We call such a graph a **Tournament**.
- Is there a path where every vertex appears exactly once.

Going back to the problem so our formulation seems to be right in the sense that what we have been asked to do is find a path where every vertex appears to be exactly once.

(Refer Slide Time: 22:13)

Hamiltonina Path

For any graph $G = (V, E)$ a **Hamiltonian Path** is a path that touches every vertices exactly once.

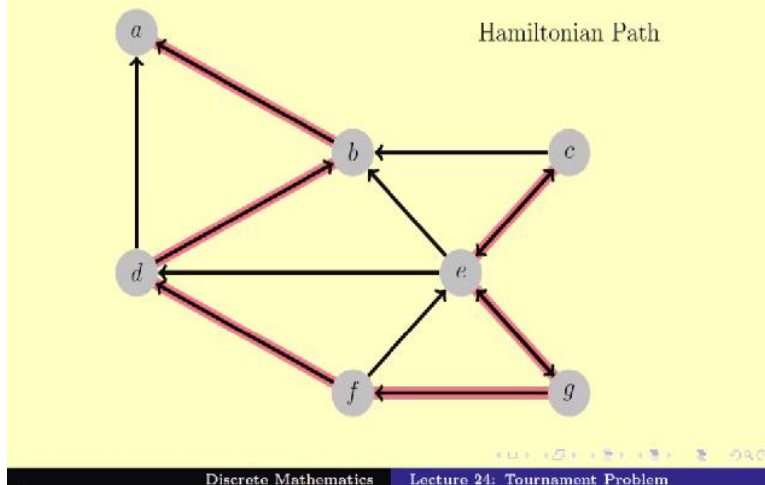

A graph may or may not have a Hamiltonian Path.

If there is cycle that touches every vertices exactly once then it is called a **Hamiltonian Cycle**.

So, such a path is called a Hamiltonian Path. A graph in general may or may not have a Hamiltonian Path. It may or may not have a –and if there is a cycle of that form it touches every vertex exactly you want. We call it as a Hamiltonian Cycle. So, graph may or may not have a Hamiltonian Cycle.

(Refer Slide Time: 22:41)

Hamiltonian Paths

So, let's look at some of the examples. So if this is a graph now let's try to see whether this graph has a Hamiltonian Path. How about this one? Now this is a path it form proper path because I can go from e to g, from g to f, f to d, d to b and b to k. But I cannot extend it to go to c if then you convince yourself that this particular graph does not have a Hamiltonian Path. But if I had to flip this, a into c and made it into a two way path.

Then I could have brought a Hamiltonian Path of this kind. C to e, e to g, g to f, f to d, e to b, b to a. So, this gives us a Hamiltonian Path. Note that this graph does not have a Hamiltonian Cycle. Also note that this graph is not at a tournament because there is no edge between a and c either this way or that way and so on. I do not have an edge between a and d also. So, in a general graph we can have a Hamiltonian Path, need not have a Hamiltonian Path.

(Refer Slide Time: 24:06)

Modelling the problem

- Let G be a tournament.
- Prove that there is a path that passes through every vertex exactly once.
- Such a path is called a Hamiltonian Path.
- So prove that every Tournament has a Hamiltonian Path.

Discrete Mathematics Lecture 24: Tournament Problem

But the problem now says that if G is a tournament that means between any pairs of vertices there is edge going from u to v or v to u proves that there is a Hamiltonian Path. So, you prove that a Tournament has a Hamiltonian Path, and this is the formulation of the problem that we have in terms of graph theory. Now, how to prove it?

(Refer Slide Time: 24:37)

How to prove it?

Hint: Induction.

Discrete Mathematics Lecture 24: Tournament Problem

Again the hint is induction. We will come back next video and prove this problem using induction. We have now converted the problem into a proven in

(Refer Slide Time: 25:24)

Next Class ...

We will use induction to prove that every Tournament has a Hamiltonian Path.

Discrete Mathematics Lecture 24: Tournament Problem

Next class we will use induction to prove that every tournament has a Hamiltonian Path. Thank you.
