Properties of Solutions Of Second-Order Homogeneous ODE's.

So we have seen second-order linear differential equation, ordinary differential equation, we have seen how it can be converted to a system, system of coupled 2 equations, first order linear equations, so we have seen how it is done. We will see, we will study today the properties of the second-order linear ordinary differential equations. So we will start with the equation. So let second-order equation is, second-order linear ODE, linear ODE.

(Refer Slide Time: 0:49)

$$\frac{d}{dx} \begin{pmatrix} y_1 \\ y_2 \end{pmatrix} = \begin{bmatrix} 0 & 1 \\ -\frac{a_2}{a_0} & -\frac{a_1}{a_0} \end{bmatrix} \begin{pmatrix} y_1 \\ y_2 \end{pmatrix} + \begin{pmatrix} 0 \\ \frac{f(x)}{a_0} \end{pmatrix} \Leftrightarrow \vec{X}' = A(x)\vec{X} + \vec{B}(x)$$
 where $\vec{B}(x) = \begin{pmatrix} 0 \\ \frac{f(x)}{a_0} \end{pmatrix}$

$$2^{\text{nd}} \text{ order linear ODE}$$

$$a_0(x)y'' + a_1(x)y' + a_2(x)y = b(x), \quad x \in I \subset \mathbb{R}$$

$$a_0(x) \neq 0 \quad I = (a, b) \text{ or } (a, \infty) \text{ or } (-\infty, a) \text{ or } (-\infty, \infty)$$

$$\Rightarrow y'' + \frac{a_1}{a_0}y' + \frac{a_2}{a_0}y = \frac{b(x)}{a_0}$$

$$\Rightarrow y'' + p(x)y' + q(x)y = r(x), \quad x \in I$$

This is $A_0 x y'' + A_1 x y' + A_2 x y = B x$. So x belongs to the domain, some interval which is in the real line. So I can be, I can be finite interval or semi-infinite interval. So I can be equal to A, B open interval or A to infinity or minus infinity, some A and some minus infinity to infinity, it is a full \mathbb{R} . Okay. So this is how, this is how I can be. Since we have seen that, whenever you have this one, the highest coefficient of the highest derivative should not be zero, so those are the x values when $A_0 \neq 0$ should not be zero.

So you have seen that $A_0 \neq 0$, that means the domain should be having all the values for which A_0 of x is nonzero. Because this is nonzero, I can rewrite, so $A_0 y'' + A_1 y' + A_2 y = B$ by A_0 into $y'' + \frac{A_1}{A_0}y' + \frac{A_2}{A_0}y = \frac{B}{A_0}$. Where $A_0, A_1, A_2, B,$

these are all given functions, so this is equal to say $y'' + p(x)y' + q(x)y = 0$ equal to some you can say $R(x)$ this is $R(x)$. $R(x)$ is B by A_0 . So x belongs to I . So what are the properties we have, properties of the solutions of second-order linear ODE which is homogeneous when R equal to 0.

(Refer Slide Time: 2:50)

The image shows a handwritten derivation in a software window titled "Differential equations for engineers - Windows Journal". The text is as follows:

$\Rightarrow y'' + p(x)y' + q(x)y = r(x), x \in I$

Properties of solutions of $y'' + p(x)y' + q(x)y = 0, x \in I$

(1) If $y_1(x), y_2(x)$ are two solutions, then $\frac{C_1 y_1 + C_2 y_2}{C_1, C_2 \text{ are constants}}$ is also a solution ✓

$y_1'' + p(x)y_1' + q(x)y_1 = 0$ & $y_2'' + p(x)y_2' + q(x)y_2 = 0$

$(C_1 y_1 + C_2 y_2)'' + p(x)(C_1 y_1 + C_2 y_2)' + q(x)(C_1 y_1 + C_2 y_2)$
 $= C_1 y_1'' + C_2 y_2'' + p(x) C_1 y_1' + p(x) C_2 y_2' + C_1 q(x) y_1 + C_2 q(x) y_2$
 $= C_1 (y_1'' + p(x)y_1' + q(x)y_1) + C_2 (y_2'' + p(x)y_2' + q(x)y_2)$
 $= 0$

For the properties, we will, we will find some properties. properties of solutions of homogeneous equations. $y'' + p(x)y' + q(x)y = 0$. So we consider only homogeneous equation, that means the right-hand side, $R(x)$ is zero. So such an equation, so we look at the solution. Suppose I give you, one, property one is, if I give you 2 solutions, y_1, y_2 are 2 solutions of this equation, then its combination, linear combination is also a solution. So let me write what exactly it is.

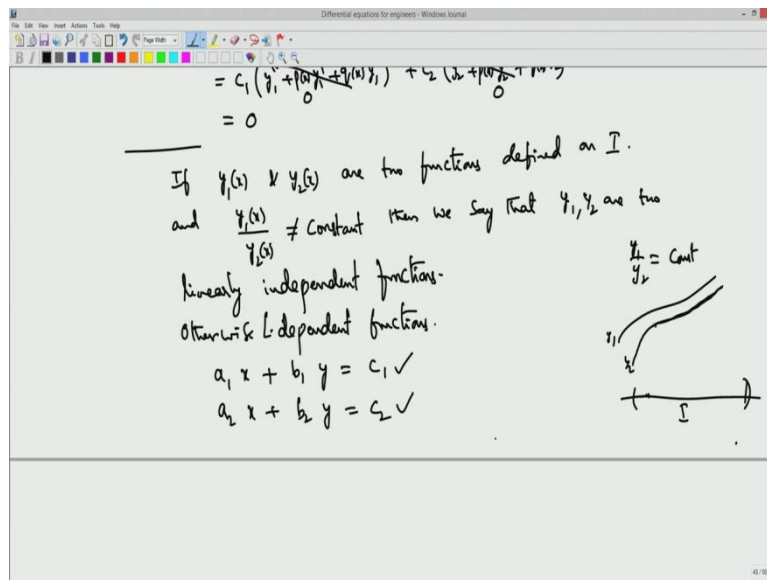

If, if I give you 2 solutions $y_1(x)$ and $y_2(x)$ are 2 solutions, then linear combination $C_1 y_1 + C_2 y_2$ is also solution. Where C_1 and C_2 are constants, C_1, C_2 are constants. So how do we see this? you know that y_1 is a solution. So you are given y_1 and y_2 are 2 solutions, so you substitute, so you see that $y_1'' + p(x)y_1' + q(x)y_1 = 0$ and $y_2'' + p(x)y_2' + q(x)y_2 = 0$. Okay. Now we want to see $C_1 y_1 + C_2 y_2$ double dash, substitute, just simply $C_1 y_1 + C_2 y_2, y_2$ into the equation, just verify whether it is zero or not.

So left-hand side I am the substituting. We have a $p(x), C_1 y_1 + C_2 y_2$ dash plus $q(x) C_1 y_1 + C_2 y_2$ equal to, what is it, this is actually equal to, you can rewrite C_1 because it is a constant, if I differentiate this, this will be $y_1'' + C_2 y_2''$ dash plus $p(x) C_1 y_1' + C_2 y_2'$

$y_1'' + p(x)y_1' + q(x)y_1$ and $y_2'' + p(x)y_2' + q(x)y_2$, this I can write, take the coefficient of C_1 , coefficient of C_2 , what you have exactly is $y_1'' + p(x)y_1' + q(x)y_1$ and here $y_2'' + p(x)y_2' + q(x)y_2$.

And we know that this is zero because these are known equations, these are known solutions. y_1 and y_2 are solutions of the equation, so this has to be zero, this has to be zero, okay. So that makes it completely zero. So that implies this one if I substitute in the place of y , is also satisfying the equation. Okay. So that implies this is also a solution. Okay. So this is how you show that. If I give 2 solutions, linear combination of, this is called the linear combination $C_1 y_1 + C_2 y_2$ is a linear combination, this is a linear combination of solutions y_1 and y_2 . This is also solution.

(Refer Slide Time: 6:41)

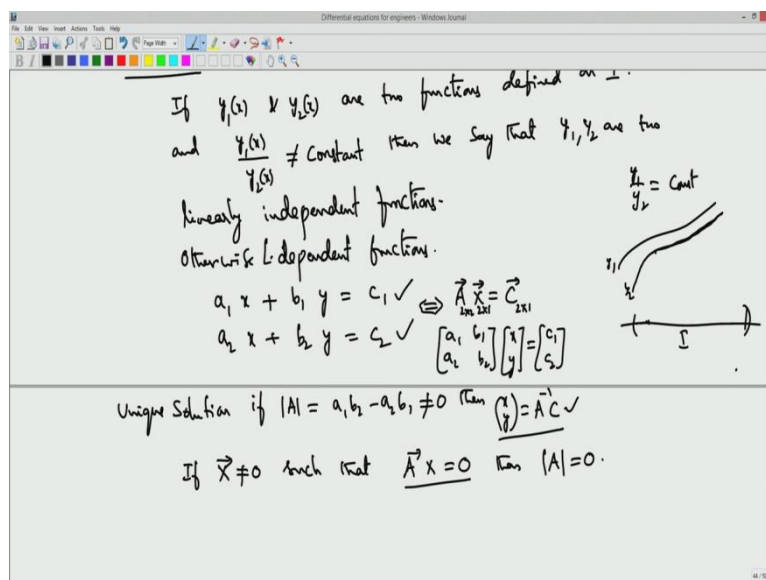

So before I proceed to give you some other properties, I define what is, what is called independence. If I give 2 functions, if $y_1(x)$ and $y_2(x)$, they are not solutions of the equation, $y_1(x)$ and $y_2(x)$ are 2 functions, 2 functions defined, defined on I . That means x belongs to I . I can be any interval, open interval. And they are and, let us say $y_1(x)$ divided by $y_2(x)$, you divide, you divide it 1 over it. If this is equal to, not a constant, if this is not equal to constant, then we say that y_1 and y_2 are 2 linearly independent, 2 linearly independent functions.

So that means 2 functions are linearly dependent if their y_1 by y_2 equal to constant, that means one is constant multiple of other. That means 2 functions like this, y_1 is this, y_2 is this, if there exactly parallel, wherever defined over I , I is from between this and this. If they are parallel, they are linearly dependent. If they are not parallel, say, let us say like this and then

goes parallelly, since they are linearly independent because because y_1 and y_2 is not a constant. It is constant upto here, upto here is constant but here, from here to here it is varying, it is not a function of, it is just, it is just function of x .

At this point, this divided by this is different, okay. So at this point you have this divided by this, this is your y_1 , this is your y_2 , y_1 by y_2 , everytime everytime you pick up the value here, so you have a different value, so it is not a constant. Okay. So we will say otherwise they are dependent, linearly dependent functions, okay. Like this $A_1 x + A_1 x + B_1 y$ equal to C_1 . And then $A_1 x + B_2 y$ equal to C_2 . Suppose you have the system of linear equations. When do you have a solution exists for these linear equations?

(Refer Slide Time: 9:38)

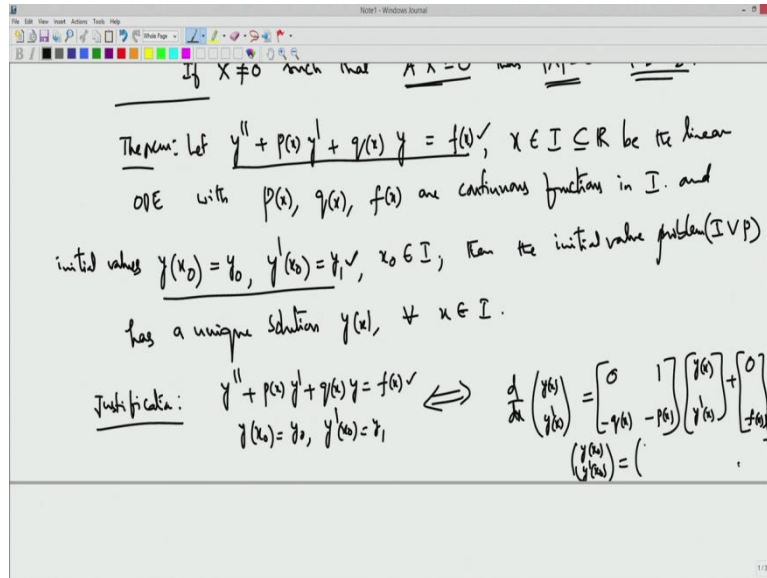

You have solution exists, solution is, unique solution is possible if the determinant, what is the determinant, if I can rewrite equivalent me, the system of equations, you can write AX equal to some C , these are, this is matrix, this is vector, this vector and this matrix, 2 by 2, 2 by 1, finally 2 by 1. So what is A , $A_1 B_1$, $A_2 B_2$, x is x , y , equal to C is C_1 and C_2 . If the determinant is, if the determinant of this matrix not A , okay, so the determinant of A that is $A_1 B_2$ minus $A_2 B_1$, if this is non-zero, I know that I can invert the equation, I can invert this matrix to get the x, y .

X, y anything but A inverse of C , okay, this is how you get. So this is the condition. So and also another way of saying is, suppose if I can find some non-zero, if x nonzero matrix, it is a vector which is nonzero, such that $A x$ equal to 0 , okay, so that means if I choose my C_1 and C_2 zero, $0, 0$, then I have a unique solution, when A is having inverse, that is zero. Okay. If

this is nonzero, so that means if this, if I have a system for which you have a nonzero solution, then I must have determinant of A should be equal to 0. Okay.

(Refer Slide Time: 11:53)

If this is non-zero, suppose this is non-zero, then I can invert it, I will get only x equal to 0 but it is given that it is x, non-zero. Okay. So before I give you property number 2, so I will explain some existence and uniqueness theorem for the linear second-order ODE, so let me write as theorem. So your equation is y double dash plus p x y dash plus q x y, let us take zero, it cannot be zero, you can take any F x, right-hand side, non-homogeneous equation, where x belongs I, I is open interval on full real line.

So let be equation, be the ODE, it is a linear ODE with p x, q x and F x are continuous functions. Suppose p x, q x and F x, differences are given and if they are continuous functions and what you have is, you have a second-order linear non-homogeneous equation and then once you see these coefficients, p x, q x and right-hand side F x, if they are continuous in I, so you have a unique solution. This equation will have a unique solution, okay. Unique solution if you provide initial conditions. So and you provide the initial conditions, that is y at x0, x0 belongs to I.

So x0 is given as y0, y dash at x0 equal to y1. So where x0 belongs I. This will be with initial values, initial values. So function value, unknown function value and its derivative is given at some point x0. Then this, the initial value problem, so that consists of this and these 2. We will have then the initial value problem, I will write this initial value problem, initial value

problem, that means this one and this one together. So IVP, you can call this IVP as a unique solution. Unique solution y x for every x in I . So we can say this one.

So this is actually, it is, so we can somehow, the proof is beyond the scope of this course, what we do is, we will just give the justification why this theorem is true. Okay. So basically proof is by converting this initial value problem this and this, you convert this as a first-order system that as we have done earlier. So if you write, some justification we can give, justification of the proof. So $y'' + p(x)y' + q(x)y = f(x)$ and you have these initial values y_1 . So this is actually, you can put it as equivalent form as $\frac{d}{dx}$ first-order system, system of equations are first-order equation for a vector valued function.

So for a vector y at x , y' at x , so this is your vector. So for this if you take the derivative, what you get is the matrix, $0, 1$ and this will be your, y of x , okay. So this is your y of x and y' of x and then see you have minus $q(x)$ minus $p(x)$. This is the matrix, if you actually do this, y' , first element is derivative. So y' equal to, if you actually take this element, this multiplication, you will that y' . y' equal to y' , so the right-hand side should be 0 .

And what happens here, the 2nd element, y'' , that is coming from this equation. That is $F(x)$, so I should have $F(x)$ here, okay I have $F(x)$ and then minus $p(x)y'$ and minus $q(x)y$, so that is how you get the system. And what is the initial value, y at x_0 , y' at x_0 . So this vector at x_0 is already known. That is given as y_0, y_1 , where y_0, y_1 are the real numbers. So this is how you see, view the second-order system like this.

(Refer Slide Time: 16:58)

has a unique solution $y(x)$.

Justification: $y'' + p(x)y' + q(x)y = f(x)$
 $y(x_0) = y_0, y'(x_0) = y_1$ \iff $\frac{d}{dx} \begin{pmatrix} y(x) \\ y'(x) \end{pmatrix} = \begin{bmatrix} 0 & 1 \\ -q(x) & -p(x) \end{bmatrix} \begin{pmatrix} y(x) \\ y'(x) \end{pmatrix} + \begin{pmatrix} 0 \\ f(x) \end{pmatrix}$
 $\begin{pmatrix} y(x_0) \\ y'(x_0) \end{pmatrix} = \begin{pmatrix} y_0 \\ y_1 \end{pmatrix}$

$X = \begin{pmatrix} y(x) \\ y'(x) \end{pmatrix} \in \mathbb{R}^2$, $F(X) = AX + B$
 $F: \mathbb{R}^2 \rightarrow \mathbb{R}^2$

$\implies \left| \frac{dF}{dX} \right| = |A| < \infty, \forall x \in I$. Then

$\frac{dX(x)}{dx} = F(X)$ has unique solution in I .
 $X(x_0) = \begin{pmatrix} y_0 \\ y_1 \end{pmatrix}$

So if you see this as a vector valued function $y(x)$, $y'(x)$ and $y''(x)$, okay, so this belongs to \mathbb{R}^2 . And what is your right-hand side, so what is your right-hand side, $\frac{d}{dx}$ of this, this is the left-hand side, remaining is the, this is what is the right-hand side, okay. This is your right-hand side, the right-hand side is actually the function of, some function of, function of, let me write this as a function of, this is you call this x , okay. So $F(x)$, it is small x , okay. It is a function of x , so $F(x)$ is $Ax + B$, that is A is, if I call this vector as x , x of x plus B .

This is a vector, this is a vector, this is a matrix, A is the matrix, okay. This is how we have with the initial value, so first of all this is what it is. So this is, this is a function from x is here in \mathbb{R}^2 . So \mathbb{R}^2 to, where it is going, so this is from 2×2 multiplying with 2×1 . So this is going to be 2×1 , okay. So 2×1 vector, 2×1 vectors together is 2×1 vector. So so it is basically again and \mathbb{R}^2 . So what is the derivative F' , okay, if I want $\frac{dF}{dx}$, this is actually, you can, you can view this as a scalar equation as the derivative is actually the matrix itself, it is an operator, okay.

So this if you do not know, this is from \mathbb{R}^2 to \mathbb{R}^2 , any differential, any derivative, derivative of F with respect to the vector is actually, think of this as $Ax + B$, so its derivative is simply A . So you have this is an operator. So this is the derivative, derivative with an operator here because it is from \mathbb{R}^2 to \mathbb{R}^2 , okay. So if this is, if this is known, so that means what is the modulus, what is, where is A , it is an operator, A is 4 elements, it is in \mathbb{R}^4 .

So modulus of that is actually square root of, squares of sum of the squares of all the 4 elements in the matrix. Okay. If that is finite for every x in I , that is true because zero is continuous function, continuous function, q is continuous function, p is continuous function, they are defined on I . Square of this, p square, q square, they all consider functions on I , they are finite, so you can say this is finite. So this is the, this is a sufficient condition. Okay. Because you have chosen them as a continuous function, they are continuous functions and these are all continuous functions, so this condition is satisfied.

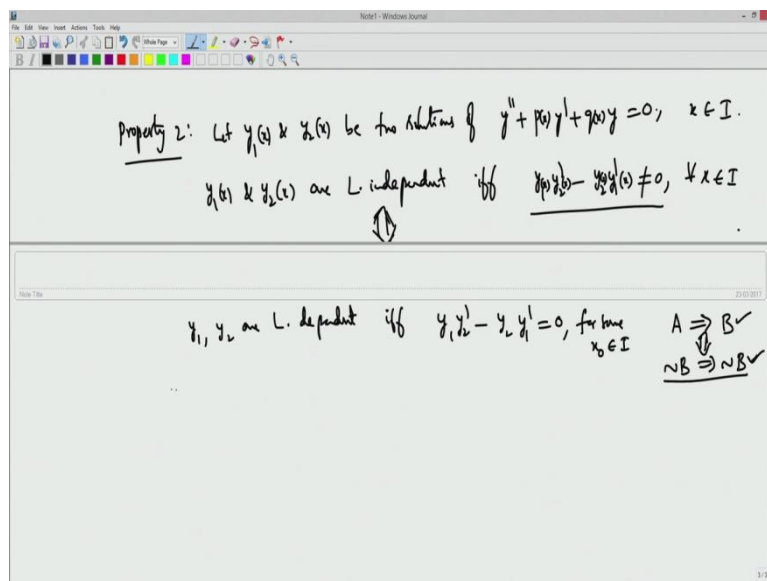

So this is can be, this is satisfied, then you have this system, the system $\frac{dx}{dt}$ by $\frac{dx}{dt}$, okay, x of x equal to F of x as unique solution with, with x at x_0 equal to some y_0, y_1 , so that is what is given. So this has unique solution, unique solution in I , okay. So, so you can also view. So this is actually, this is more general theorem, so if you have a system like this, if this is true, this is bounded in a rectangle like this. So you take this x_0 , so initial value is x_0 and your, this you think of \mathbb{R}^2 . Okay.

This is your x , this is your x , this is your x and this is your capital X . So you are actually in the space. So at this point you will have some rectangle, so if at all the neighbourhood, the neighbourhood of x_0 , so let us say this is your I . x_0 is here. So you will have a box containing x_0 and that y_0, y_1 , middle point is y_0 . So this middle point is actually x_0, y_0, y_1 . Because y_0, y_1 is in x . Okay. So in this neighbourhood, in this box, if these functions are continuous, you will have the unique solution.

So passing through you will have the space curve in the x . That means you have a y_x in the neighbourhood of x_0 , okay. That is what is the existence theorem. But if you see that there is a global existence, if you see that it is actually continuous, if you function is, it is, I remove this, lower, upper rectangle. So if this is full, okay, for every x_0 belong to I , y_0, y_1 , that takes all the values, let us take whatever all the vector is here and there is in this direction, okay. If in that if this is true, that is actually true, because there are only functions which are only depending on this, x variable.

So they are all bounded, so in that case you will have a global solution, not only the neighbourhood, so it will be, you will have full, after here, whenever it is defined in the full I . So that is what is the existence uniqueness theorem, you will have unique solution, you have a solution, it is actually unique. Okay. So you can assume that without proof, kind of justification is this is what you will see in the textbooks. If you are interested you can get into some reference books, you can see that existence theorem, you might see this form, so that this same as this form. Okay.

(Refer Slide Time: 22:39)

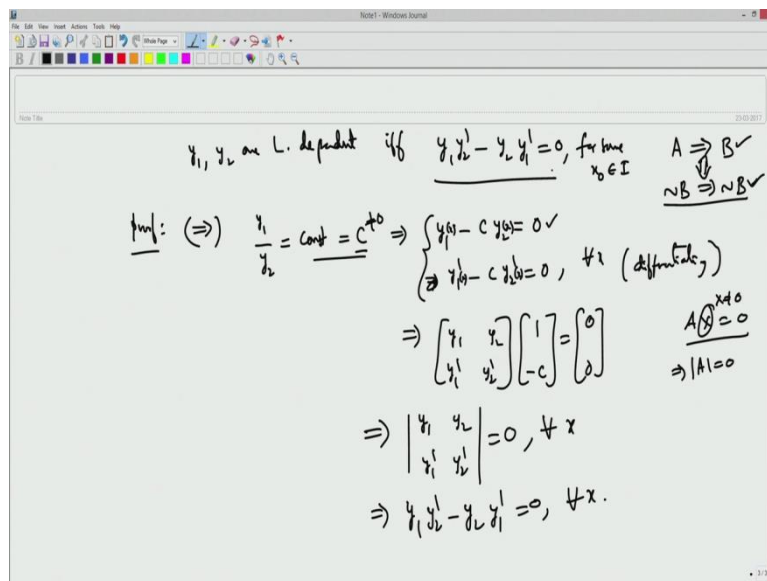

So with this I will give a property number 2, so property 2, property 2 is if you are given the homogeneous second-order linear homogeneous equation, that is let y_1 and y_2 be 2 solutions, 2 solutions of $y'' + p(x)y' + q(x)y = 0$ where x belongs to I . If it is given, when do I know that they are linearly independent? So $y_1(x)$ and $y_2(x)$ are linearly independent if and only if I will have some expressions to be satisfied by these functions y_1 and y_2 , by the solutions y_1 and y_2 . That is $y_1(x)y_2'(x) - y_2(x)y_1'(x)$ which are which are functions of x , which has to be not equal to 0 for every x in I . So this is what is the property number 2. So we can say if you are given 2 solutions which you do not know how to find but if you are, as you are having 2 such solutions, then you can say whether they are linearly independent or not, they are linearly independent if you can check this condition, okay.

So this is equivalent to, this is equivalent to put it in this way. So if you if you know the logic A implies B , counter positive is not B implies not A , so you can put it in that form. So if I write, if I use that logic, if this is, if these are equivalent, these 2 statements are equivalent, keeping this in mind, you can rewrite the property as y_1 and y_2 are linearly, y_1 and y_2 are linearly dependent if and only if $y_1(x)y_2'(x) - y_2(x)y_1'(x) = 0$ for every x in I . Okay.

I can do like this, for some x_0 belongs to I . Right. So if this is not true, that means there is some x_0 , if this is not true, there is, there will be some x_0 that is true implies they are linearly dependent. If they are linearly dependent, so that means you are going from here to there. So if they are linearly independent, the not of this, not of this is there exists some x_0 that belongs to I such that this quantity is zero. So we will prove this statement in a straightforward way.

(Refer Slide Time: 25:26)

If you write, rewrite like this, this we can prove nicely. Okay. So start with they are linearly dependent. So what you mean by, so we will go from this side, okay. So we will prove from this side, assuming that y_1 and y_2 are linearly dependent, then we will show that this point is zero, some point. Okay. So they are linearly dependent means they are actually parallel. That means y_1 by y_2 is a constant, okay. Let us call this some C , that implies y_1 minus $C y_2$ equal to 0. Okay. So you can differentiate this because y_1 and y_1, y_2 are satisfying, second-order equations, if you differentiate y_1 dash minus C , this is a constant, y_2 dash is also zero.

This is true for every x , okay, this is true for every x . So this means, this together means, this is by differentiating, differentiating the first, this equation you can get this equation. So this you can write as a matrix, y_1, y_2, y_1 dash, y_2 dash, matrix and 1, minus C equal to 0, 0. So I know that C is a constant and they are dependent means and once they are linearly dependent, I, you are given that they are nonzero solutions, 2 nonzero solutions, okay, you can take it as 2 nonzero solutions.

If there are 2 nonzero solutions, this constant should be nonzero, okay. So this constant should be nonzero, so you have 1, minus C like that you have nonzero solutions for a system $A x$ equal to 0. So when do you have nonzero solutions for the system, that means the determinant A has to be zero. Okay. And x is non-zero satisfying this, implies non-zero. So that implies modulus of A has to be zero, that means here, what is the modulus of y_1, y_2, y_1 dash, y_2 dash equal to 0 for every x .

That means this is exactly your condition, $y_1 y_2' - y_2 y_1' = 0$ for every x . So we only need at some point, so we can take some x_0 . So that means this is true. So if this is dependent, I prove this one, it is straightforward, okay.

(Refer Slide Time: 27:55)

(\Leftarrow) If $y_1 y_2' - y_2 y_1' = 0$, for some $x_0 \in I$.

$$\begin{bmatrix} y_1(x_0) & y_2(x_0) \\ y_1'(x_0) & y_2'(x_0) \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

 $\Rightarrow \exists \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} \neq \begin{bmatrix} 0 \\ 0 \end{bmatrix}$
 $\phi(x) = c_1 y_1(x) + c_2 y_2(x)$ satisfies $y'' + p(x)y' + q(x)y = 0$
 $\phi(x_0) = c_1 y_1(x_0) + c_2 y_2(x_0) = 0$
 $\phi'(x_0) = c_1 y_1'(x_0) + c_2 y_2'(x_0) = 0$

$AX=0$
 $|A|=0 \Rightarrow$
 $\exists X \neq 0$ such
 that $AX=0$

So let us prove the other way that if I assume the condition is or, okay. If I assume $y_1 y_2' - y_2 y_1' = 0$ for some, okay, for some x_0 belong to I , then I want to show that they are linearly dependent. So what you do is, you consider the same system, so whatever you have y_1 but you consider at those values, okay. y_1 at x_0 , y_2 at x_0 , so the system you consider, okay. So y_1' at x_0 , y_2' at x_0 , this matrix into some C_1 and C_2 , some constants, you take it, you do not know this, okay.

So you consider this system, so you have A , you consider AX equal to 0 where A is given like this with these values where y_1, y_2 have the values, y_1 and y_2 and its derivatives at the point at x_0 , okay, for which this quantity is zero. So you have, you consider the system and you know that this determinant is zero. So you know that this determinant is zero, that is what is given implies if the determinant of A is zero, implies I will have a nonzero solution, okay.

There exists nonzero x_0 , such that Ax equal to 0. So you have nonzero solution for C_1 and C_2 , so that implies there exists C_1, C_2 matrix, vector nonzero, so you will get such a nonzero solution, okay. Now we consider, we consider some $\phi(x)$, which is, you make it C_1 with y_1 x , with these constant, with this constant, so let us assume that both are nonzero, okay. Now you will see that both of them has to be nonzero, one cannot be zero and one. So certainly

this is nonzero means one of them is not zero. You will see that both of them are actually not zero. Okay.

So whether they are zero or not, one of them or both of them, whether you know, was there one of them is zero or not, with these you know that there exists some C_1 and C_2 vector which are nonzero, as a vector it is not zero. That means it can be, one of them can be zero. Such a C_1 and C_2 , you form some function ϕ like this, $C_1 y_1 x$ plus $C_2 y_2 x$ because y_1, y_1 and y_2 are solutions of the homogeneous equation. So what happens, this satisfies, once you form this, this satisfies equation, the equation, the ODE, the ODE is, the equation is $y'' + p(x)y' + q(x)y = 0$.

And what are its value at x_0 , ϕ at x_0 is $C_1 y_1$ at x_0 plus $C_2 y_2$ at x_0 . What is its value, this is simply, you multiply this vector with this. That is $y_1 C_1$ plus $y_2 C_2$ at x_0 that is zero. So that is zero. And similarly ϕ' at x_0 , if you actually from ϕ x is this, ϕ' if you calculate, $C_1 y_1'$ plus $C_2 y_2'$ at x , that is the derivative at x . You put x equal to x_0 , and then this becomes $y_1' C_1$ plus $y_2' C_2$ is also zero. Okay.

(Refer Slide Time: 32:28)

$$\begin{bmatrix} y_1(x) \\ y_2(x) \end{bmatrix} \begin{bmatrix} C_1 \\ C_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\Rightarrow \exists \begin{bmatrix} C_1 \\ C_2 \end{bmatrix} \neq \begin{bmatrix} 0 \\ 0 \end{bmatrix} \checkmark$$

$$\checkmark \phi(x) = C_1 y_1(x) + C_2 y_2(x) \text{ satisfies } y'' + p(x)y' + q(x)y = 0$$

$$\phi(x_0) = C_1 y_1(x_0) + C_2 y_2(x_0) = 0 \checkmark$$

$$\phi'(x_0) = C_1 y_1'(x_0) + C_2 y_2'(x_0) = 0 \checkmark$$

$$\checkmark \phi(x) \equiv 0, \forall x \in I \text{ also satisfies the equation and the initial values } y(x_0) = 0, y'(x_0) = 0$$

$$\Rightarrow \phi(x) = 0 \Rightarrow C_1 y_1(x) + C_2 y_2(x) = 0 \checkmark$$

$$\Rightarrow y_1(x) = -\frac{C_2}{C_1} y_2(x) \Rightarrow \frac{y_1}{y_2} = \left(-\frac{C_2}{C_1} \neq 0\right) \text{ const}$$

Now from the uniqueness because p and q are continuous functions and you do that, if we take this, so with this ϕ satisfying this equation and these are the initial condition ϕ at x_0 and ϕ' at x_0 is zero. So that you have such a solution, $C_1 y_1$ plus $C_2 y_2$, okay. And you know that zero is also satisfying, y of x equal to completely zero for every x in I also satisfies

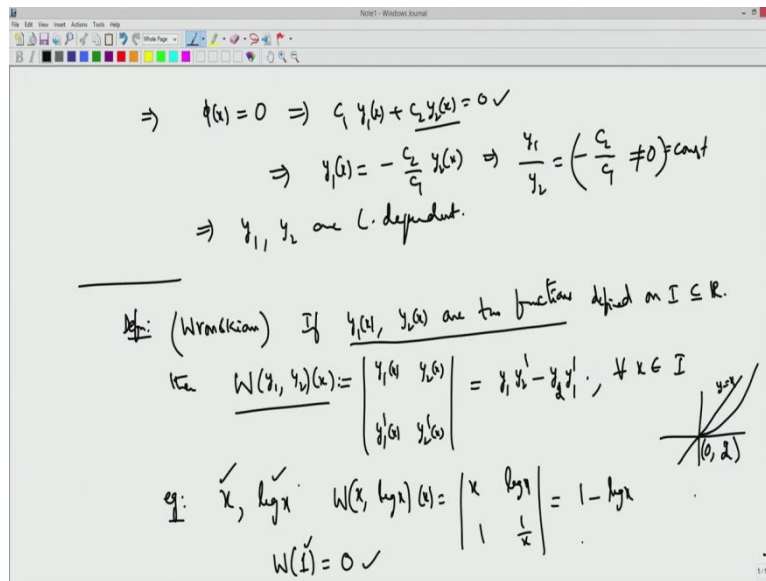

the equation and the initial values, initial values. Y at x_0 is zero, y' at x_0 is also zero. Because you simply differentiate yx equal to 0, you get that. Okay.

So I have 2 such functions, ϕ is also satisfying the initial value problem, zero is also satisfying the initial, by the uniqueness of the solution, for the differential equation with the initial condition, okay. By uniqueness of the initial value problem, this ϕx should be equal to 0. So what is ϕx ? $C_1 y_1$ of x plus $C_2 y_2 x$ should be equal to 0. So that means I can write $y_1 x$ equal to minus C_2 by C_1 , okay into $y_2 x$. That implies y_1 by y_2 minus C_2 by C_1 . So this is not a constant, okay. Assume that C_2 is zero, if C_2 is zero, okay, we feel that this is not zero, this is, as a vector this is not zero.

So if C_2 is zero and C_1 is non-zero, then C_1 into y_1 , because y_1 is a nonzero function, C_1 has to be zero. So both, that is not true. If C_2 is zero, C_1 is also zero why, from this, okay. Assume that you have got some C_1 and C_2 satisfying this, you are working with those C_1 and C_2 . Assume that C_2 is zero, then my C_2 will be zero here, then $C_1 y_1$ will be zero. That means C_1 also will be zero, okay. C_1 is zero because y_1 is nonzero solution. So both, if C_2 is zero, C_1 is also zero.

So that means both C_1 and C_2 should not be zero. If you want this vector C_1 and C_2 , this is nonzero. So that means C_1 , C_2 , both are nonzero that means the ratio is also nonzero. So this is exactly constant, right. This is exactly constant, is a constant, that implies this is exactly the definition of y_1 , y_2 are linearly dependent, they are parallel to each other. Okay. So that is how you show, so if you are given a 2 linearly independent solutions, 2 solutions, 2 nonzero solutions of the homogeneous equation, they are linearly independent if and only if this condition is satisfied, this condition is non-zero for every values of x .

(Refer Slide Time: 35:09)

That is equivalently we are putting in this way and then we shown nicely, very easily just by considering a small system we can show that they are dependent if and only if that quantity is zero at some point x_0 , okay. So this naturally, so we can define naturally, so that is the definition, so there is, whatever you see on the right-hand side, the quantity, we can define as a Wronskian, this is a Wronskian of, Wronskian of 2 functions okay.

Wronskian of, so if y_1, y_2 are 2 functions, 2 functions defined on, defined on I which is in \mathbb{R} . Then Wronskian of y_1, y_2 of x is defined as the determinant, that is $y_1(x), y_2(x), y_1'(x)$, and $y_2'(x)$. So this is your y_2 . This is, this determinant is nothing but your quantity. So $y_1 y_2'$ minus $y_2 y_1'$ or $y_2 y_1'$ dash, so this is exactly, this called Wronskian, this is the definition of Wronskian. So if you are given, these are you see, you can, you can note that these are 2 functions, I define this Wronskian like this for every x in I . Okay.

So these are only 2 functions, they are not solutions of the linear homogeneous equations. If they are linearly, if they are solutions of the linear second-order homogeneous equation, then they are linearly independent if and only if this Wronskian should not be zero at every point, okay. So but this is not true for general functions. You can consider some example like I give you. So $1, \log x$, I consider these 2, okay. So what is the Wronskian, Wronskian of these 2 functions, Wronskian of $1, \log x$ or $x, \log x$.

If you think of $x, \log x$, let me see and we define the domain later, so this is simply $x, \log x, 1, 1$ by x . Okay. So what is the determinant, 1 minus $\log x$. So you can see this, you know that $x, \log x, x, \log x$ is, x is, y equal to x is this, okay. y equal to x, y equal to $\log x$ is some other

things, right, it goes like this. Simply you define only between open into will 0 to 1, 0 to 2 let us say. You see that these functions are clearly linearly independent but they are not the solutions of any differential equation, right.

Because the Wronskian can be zero, Wronskian is this, Wronskian at x equal to 1, okay, Wronskian of x , $\log x$, so function of x at 1, this is zero. Okay. Wronskian is zero, Wronskian is 0 implies, Wronskian at some point, it is 0, right, so at 1, at 1 it is zero, so it implies they have to be linearly dependent. That means they have to be parallel to each other but that is not the case that is true, that means if you want the Wronskian, if you want the Wronskian is 0 at some point, there, then the functions y_1 y_2 are linearly dependent only if they are the solutions of, that is true, only if, that is true only when these are the solutions of second-order linear homogeneous equation, okay, not for other functions, this is the example, okay.

(Refer Slide Time: 39:04)

$$W(y_1, y_2)(x) = \begin{vmatrix} y_1(x) & y_2(x) \\ y_1'(x) & y_2'(x) \end{vmatrix} = y_1 y_2' - y_2 y_1', \quad \forall x \in I$$

eg: $x, \log x$
$$W(x, \log x)(x) = \begin{vmatrix} x & \log x \\ 1 & \frac{1}{x} \end{vmatrix} = 1 - \log x$$

$$W(1) = 0 \checkmark$$

Property 3: If $W(x_0) = 0$ ($\neq 0$) then $W(x) = 0$ ($\neq 0$), $\forall x \in I$.

So this if you consider these 2, though the Wronskian is zero, they are not actually linearly dependent. Okay. So we will have a property 3, property 3 in the next video that tells you that if Wronskian of, Wronskian at some point is zero or non-zero, okay, then Wronskian at x at every point is zero or nonzero every point. So this is done by deriving a formula called Abel's formula. Okay. So next class we will derive Abel's formula and then we will see this property 3. So once the Wronskian is zero and the Wronskian is 0 Everytime.

The Wronskian is nonzero at some point, then the Wronskian should be nonzero at every other point. This is proved by looking at a formula called Abel's formula, we will see in the next video.
