Properties of Legendre Polynomials

So in the last video we have derived orthogonal property. We are giving some properties of Legendre polynomials. First property is orthogonal property with most important property and in that we are saying that any two different Legendre polynomials will be orthogonal and we have seen that if you take the same polynomial and you integrate so you will have some value.

So while doing that so in this video so we will derive another expression directly from the recurrence relation of the Legendre equation from which you can directly derive this formula for the Legendre polynomial $P_n(x)$, okay. So before I do that so in the last video we have done this integral value. So we have seen this integral value as this, okay.

So we can see that so 2 times when you do that dx by, so that 2 actually cancels, okay. When you are doing so $2x dx$ equal to dt so when you are replacing with dx which is dt by $2x$ so the 2 2 cancels, 1 by x is actually t power minus half. So you do not have this 2, okay.

(Refer Slide Time: 01:37)

The image shows a whiteboard with handwritten mathematical derivations. On the left side, the main result is written as:

$$\Rightarrow \int_{-1}^1 P_n^2(x) dx = \frac{2}{2n+1}, \quad n \in \mathbb{Z}$$

On the right side, the derivation is shown in several steps:

$$= \frac{(2n+1)!}{(2n+1)!} \int_{-1}^1 (1-x^2)^n dx = 2 \int_0^1 (1-x^2)^n dx$$

Then, a substitution $x^2 = t$ is used, leading to:

$$= \int_0^1 (1-t)^n t^{-1/2} dt$$

This is identified as a beta function:

$$= \beta\left(\frac{1}{2}, n+1\right) = \frac{\Gamma(1/2)\Gamma(n+1)}{\Gamma(n+3/2)}$$

Finally, the relationship $\Gamma(n+1) = n \Gamma(n)$ is noted.

So this value you will see that is actually this one so 2 times finally you will see that this is what you will get, okay. So we will see that how it is done today. So what you need is this

beta function at half n plus 1 which is Gamma half into Gamma n plus 1. So n is an actual number so you can find this n plus 1 plus half, okay.

So this is equal to so Gamma half is root pi and this is n factorial divided by, this you can write using this formula as n plus half Gamma, so Gamma n plus half, okay. So again I can rewrite like n plus half. So that is actually plus half, n plus half I write like minus 1 plus 1 plus half. So it is again like, right? Okay so half plus 1 rather n minus 1 plus half plus 1. So this is actually this, okay. And you actually see n plus half plus 1 is n plus half into Gamma n plus half, 1 goes.

Just add and subtract it 1 so again you can rewrite Gamma root pi into n factorial divided by n plus half times, again n minus 1 plus half that is n minus half. So this is going to be n minus half into Gamma n minus 2 plus half plus 1. So that is what you will see. What is this actually? N minus 1 plus n minus half. So n minus half into Gamma n minus half, okay.

(Refer Slide Time: 03:51)

The image shows a handwritten derivation of the beta function. At the top, it states the integral definition: $\int_{-1}^1 p_n^{1/2}(t) dt = \frac{2}{2n+1}$, where $n \in \mathbb{Z}$. To the right, it shows the transformation of the beta function integral: $\int_0^1 (1-t)^{n-1/2} t^{1/2} dt = \int_0^1 (1-t)^{(n+1)-1} t^{1-1/2} dt = \beta(1/2, n+1) = \frac{\Gamma(1/2)\Gamma(n+1)}{\Gamma(n+3/2)}$. Below this, it shows the relationship $\Gamma(n+1) = n\Gamma(n)$. The main derivation shows:
$$\beta\left(\frac{1}{2}, n+1\right) = \frac{\Gamma\left(\frac{1}{2}\right) \cdot \Gamma(n+1)}{\Gamma\left(n+1+\frac{1}{2}\right)}$$

$$= \frac{\sqrt{\pi} \cdot n!}{\left(n+\frac{1}{2}\right) \Gamma\left(n-1+\frac{1}{2}+1\right)} = \frac{\sqrt{\pi} \cdot n!}{\left(n+\frac{1}{2}\right) \left(n-\frac{1}{2}\right) \Gamma\left(n-2+\frac{1}{2}+1\right)}$$

So like that you go on every time you do this. This is actually n minus half, n minus half I am rewriting n minus 2 plus half plus 1, okay. So next time when you write n minus 3 plus half plus 1 will be this is actually this is this into Gamma of this into n minus whatever is here. So this is going to be n minus 2 plus half. N minus 2 plus half is n minus 3 by 2. So this into this is actually equal to this.

(Refer Slide Time: 04:29)

The image shows a digital notebook with handwritten mathematical derivations. The top section shows the integral of x^n from -1 to 1 is $\frac{2}{2n+1}$ for $n \in \mathbb{Z}$. To the right, the Beta function $\beta(\frac{1}{2}, n+1)$ is defined as $\frac{\Gamma(\frac{1}{2})\Gamma(n+1)}{\Gamma(n+\frac{1}{2})}$. The bottom section shows the derivation of $\Gamma(\frac{1}{2})$ as $\sqrt{\pi}$ by equating the Beta function to $\frac{\sqrt{\pi} \cdot n!}{(n+\frac{1}{2})\Gamma(n-\frac{1}{2})}$ and simplifying.

$$\Rightarrow \int_{-1}^1 x^n dx = \frac{2}{2n+1}, \quad n \in \mathbb{Z}$$

$$\beta\left(\frac{1}{2}, n+1\right) = \frac{\Gamma\left(\frac{1}{2}\right) \cdot \Gamma(n+1)}{\Gamma\left(n+\frac{1}{2}\right)}$$

$$= \frac{\sqrt{\pi} \cdot n!}{\left(n+\frac{1}{2}\right) \Gamma\left(n-\frac{1}{2}\right)} = \frac{\sqrt{\pi} \cdot n!}{\left(n+\frac{1}{2}\right) \left(n-\frac{1}{2}\right) \Gamma\left(n-\frac{3}{2}\right)}$$

So you can replace like this, you can go on writing like this, what you see is you will end up n minus 3 by 2 and so on. Finally you will end up just 5 by 2. So if you keep on adding so n is a fixed number, fixed natural number so we have 3 by 2. So you see that 5 by 2, 3 by 2 and finally we get 1 by 2. So when you get 1 by 2, Gamma will be n equal to 1 in this case for example, okay, n equal to 1 this is going n half plus 1 that is half into Gamma half. The Gamma half is again root pie. So this root pie this root pie goes, okay.

(Refer Slide Time: 05:16)

This image is identical to the previous one but shows a more detailed expansion of the Gamma function in the denominator of the Beta function expression. The final expression is $\frac{\sqrt{\pi} \cdot n!}{\left(n+\frac{1}{2}\right) \left(n-\frac{1}{2}\right) \left(n-\frac{3}{2}\right) \dots \frac{5}{2} \cdot \frac{3}{2} \cdot \frac{1}{2} \sqrt{\pi}}$.

$$\Rightarrow \int_{-1}^1 x^n dx = \frac{2}{2n+1}, \quad n \in \mathbb{Z}$$

$$\beta\left(\frac{1}{2}, n+1\right) = \frac{\Gamma\left(\frac{1}{2}\right) \cdot \Gamma(n+1)}{\Gamma\left(n+\frac{1}{2}\right)}$$

$$= \frac{\sqrt{\pi} \cdot n!}{\left(n+\frac{1}{2}\right) \left(n-\frac{1}{2}\right) \left(n-\frac{3}{2}\right) \dots \frac{5}{2} \cdot \frac{3}{2} \cdot \frac{1}{2} \sqrt{\pi}}$$

So we can easily see that this is going to be n factorial divided by, if you write n plus 1 divided by 2, this is going to be $2n$ minus 1 divided by 2, this is going to be $2n$ minus 3 divided by 2 and so on, 5 by 2, 3 by 2 and 1 by 2. This is what you have. So in between you

add 2, 4, 6, okay, and so on. You have here $2n - 2$. You have $2n$. So what you added 1, 2, 4 actually 2, 4, 6, 8 up to $2n$ that is actually 2^n into $n!$, okay.

And you see this how many are there? I have in the division one, two, three, four, five, up to I have $n + 1$ you have in between, okay. These 2s in the denominator how many are there? If n equal to 2 this is going to be 2 into 2 plus 1, 5 by 2 up to here. So if n equal to I have three 2s. If n equal to 3, 7 by 2 that means I will have 4. So if n equal to 3 I am getting 3. So like that if you have n you will have $n + 1$ 2s, okay. These you can take it up, bring it up.

So what you have is $n + 1$ into 2^n into $n!$ divided by, now this is 1, 2, 3, 4, 5, up to $2n + 1$ factorial, divided by 2^{n+1} that will go here, okay.

(Refer Slide Time: 06:55)

The image shows a handwritten derivation in a software window titled "Differential equations for engineers - Windows Journal". The derivation starts with the integral of $P_n^2(x)$ from -1 to 1 , where $n \in \mathbb{Z}$. It then shows the integral as a beta function $\beta(\frac{1}{2}, n+1) = \frac{\Gamma(\frac{1}{2})\Gamma(n+1)}{\Gamma(n+\frac{1}{2})}$. A note states $\Gamma(k+1) = k\Gamma(k)$. The derivation continues to show $\Gamma(\frac{1}{2}) = \sqrt{\pi}$ and $\Gamma(n+\frac{1}{2}) = \frac{n!}{2^n} \sqrt{\pi}$. The final result is $\int_{-1}^1 P_n^2(x) dx = \frac{2^n n!}{(2n+1)!}$.

So this is equal to $n!$ square 2^n , $n!$ rather we write 2^n , $n!$ factorial whole square into 2 divided by $2n + 1$ factorial. This is exactly what you have here. This is what you get, okay. So let us see how we get a different formula for the P_n of x ? A new formula, okay, new formula for P_n of x . So this is also one kind of property, okay. And so we have seen one property that is the P_n s are orthogonal, okay. So $P_n P_m$ are actually satisfying orthogonal property.

So we have seen this orthogonal property that is as a property 1 and we see that second if you want to write as this property, second property is property 2 you can write, P_n of x , n is from 0 1 2 onwards or n belongs to \mathbb{Z} in fact, any \mathbb{Z} , okay. Any integer n you have is a bounded solution for your Legendre equation. What is that equation? $(1-x^2)y'' - 2xy' + n(n+1)y = 0$. So this is what you have, okay.

(Refer Slide Time: 08:46)

The image shows a whiteboard with handwritten mathematical work. At the top, there is a fraction:

$$\frac{(2n+1)(2n) \dots (n-1)(n-1) \dots (2n-1)}{2 \dots 2} = \frac{(2n+1)!}{2^n n!}$$
 Below this, it is simplified to:

$$= \frac{2(2^n n!)^2}{(2n+1)!}$$
 A property is listed:

Property: $P_n(x)$, $n \in \mathbb{Z}$ is a bounded solution for the Legendre equation $(1-x^2)y'' - 2xy' + n(n+1)y = 0$.

 At the bottom, it says:

New formula for $P_n(x)$:

So you see that how minus 1 and 1 are singular points but this function is defined because these are polynomials, we have a solutions which are as a function they are defined everywhere, but as a solution they are actually valid between minus 1 to 1. Even at those points minus 1 to 1 they are actually bounded. So its value is defined, okay. So you see that this is the bounded solution. So you have a bounded solutions for this equation. So that is I can take it as property.

We will give now a new formula for this. So to give this let us go back to the equation. So what we have done when we started solving this equation, what we derived is you put it as series solutions. When you put the series solution you get a recurrence relation like this. When you equate this x power 0, n equal to 2, n equal to 3, okay. What you have is this and now what you have is this one. So where is the recurrence formula. You have a recurrence formula here. So what you have is this is equal to 0. This formula is called recurrence relation.

(Refer Slide Time: 10:02)

The image shows a digital whiteboard with handwritten mathematical work. At the top, there is a sum of terms: $+ 2C_2 + 6C_3x$. Below this, the equation is written as $\Rightarrow 2C_2 + \alpha(\alpha+1)C_0 + [6C_3 - 2C_1 + \alpha(\alpha+1)C_1]x + \sum_{n=2}^{\infty} (n+1)(n+2)C_{n+2}x^n$. This is followed by $+ \sum_{n=2}^{\infty} [-n^2 - n + \alpha(\alpha+1)]C_n x^n = 0$. A recurrence relation is derived: $(\alpha-n)(\alpha+n+1) = \alpha^2 + \alpha - n^2 - n = \alpha(\alpha+1) - (n+1)n$. The next line shows the combined equation: $\Rightarrow 2C_2 + \alpha(\alpha+1)C_0 + [6C_3 - 2C_1 + \alpha(\alpha+1)C_1]x + \sum_{n=2}^{\infty} [(n+1)(n+2)C_{n+2} + (\alpha-n)(\alpha+n+1)C_n]x^n = 0$. Below this, the coefficients for x^0 and x^1 are determined: $\text{Coeff } x^0: C_2 = -\frac{\alpha(\alpha+1)}{2}C_0$ and $\text{Coeff } x^1: C_3 = \frac{2 - \alpha^2 - \alpha}{3 \cdot 2}C_1 = -\frac{(\alpha+2)(\alpha-1)}{3 \cdot 2}C_1$. At the bottom, the recurrence relation for $n=2$ is given: $n=2: 3 \cdot 4 C_4 + (\alpha-2)(\alpha+3)C_2 = 0$.

If this is equal to 0 when you substitute the power series solution into the equation which is equal to 0 all the powers of x power n coefficient should be 0. So this is a recurrence relation, okay, recurrence relation. So we will pick up this one. So this is the recurrence relation and actually n is from 2 to infinity. So if I put n equal to 1, n equal to 1 is actually 2 into 3 C 3 minus, okay, so that is what you have 6 C 3 and then you have here, so alpha into alpha plus 1 and n equal to 1 alpha into alpha plus 2, okay.

Alpha minus 1 into alpha plus 2 into C 1. So that is exactly you have alpha square plus alpha minus 2, okay. So this is what if you actually sum it together this is what you have, okay, into C 1, right? Alpha square plus alpha minus 2 into C 1. So that is what you have.

(Refer Slide Time: 11:11)

The image shows a digital whiteboard with handwritten mathematical work, continuing from the previous slide. It repeats the same initial steps: $\Rightarrow 2C_2 + \alpha(\alpha+1)C_0 + [6C_3 - 2C_1 + \alpha(\alpha+1)C_1]x + \sum_{n=2}^{\infty} (n+1)(n+2)C_{n+2}x^n + \sum_{n=2}^{\infty} [-n^2 - n + \alpha(\alpha+1)]C_n x^n = 0$. The recurrence relation is $(\alpha-n)(\alpha+n+1) = \alpha(\alpha+1) - (n+1)n$. The combined equation is $\Rightarrow 2C_2 + \alpha(\alpha+1)C_0 + [6C_3 - 2C_1 + \alpha(\alpha+1)C_1]x + \sum_{n=2}^{\infty} [(n+1)(n+2)C_{n+2} + (\alpha-n)(\alpha+n+1)C_n]x^n = 0$. The coefficients for x^0 and x^1 are determined: $\text{Coeff } x^0: C_2 = -\frac{\alpha(\alpha+1)}{2}C_0$ and $\text{Coeff } x^1: C_3 = \frac{2 - \alpha^2 - \alpha}{3 \cdot 2}C_1 = -\frac{(\alpha+2)(\alpha-1)}{3 \cdot 2}C_1$. At the bottom, the recurrence relation for $n=2$ is given: $n=2: 3 \cdot 4 C_4 + (\alpha-2)(\alpha+3)C_2 = 0$. This leads to $\Rightarrow C_4 = -\frac{(\alpha+3)(\alpha-1)}{4 \cdot 3}C_2 = \frac{(\alpha+3)(\alpha+1)\alpha(\alpha-2)}{4!}C_0$. To the right, there are additional terms: $(\alpha-1)(\alpha+2)C_1$ and $(\alpha^2 + \alpha - 2)C_1$.

So this is exactly even when n equal to 1 you get this expression. So n equal to 0 you get this expression. So this recurrence relation is actually valid from n equal to 0 to infinity, okay. So we can put this together inside. By just writing n equal to 0 to infinity this is what we have. So let us use this n plus 1, n plus 2. So we use this recurrence relation. So n plus 1, n plus 2, so let me write into C_{n+2} equal to minus alpha minus n into alpha plus n plus 1 into C_n , okay.

For every n greater than or equal to 0. So this I included both the first two terms. What we derived earlier, okay. So this is true. So this implies what we did is if you fix n as a natural number, okay, if you fix your n and when n is odd or n is even what you see is that n is even. So let us say some $2k$. Even let us say some $2k$. So if it is $2k$, $2k$ you get C_{2k} , okay. So C_0 you are not able to use. So you get C_0, C_2, C_4 , okay. C_2 in terms of C_0 , C_4 in terms of C_0 , like that you go up to C_{2k} in terms of C_0 . That is what we did, alright?

(Refer Slide Time: 13:00)

So you put n equal to 0 I get C_2 in terms of C_0 . Like that C_4 in terms of C_2 which we already know that this is again C_2 . C_2 is also in terms of C_0 so we have C_4 . Like that you can go up to $2k$ is in terms of C_0 . This is what we did. This is what normally we can get and substitute into the equation, right? When n is even, y_1 first solution in terms of C_0 you will have all beyond C_{2k+2} will be 0, okay. So this one is the polynomial that will stay up to $2k$ terms, okay.

So you basically you get a polynomial. If n is odd, okay, this is even. If n is odd say 2 k plus 1. In this case what you have is C 1. You start with C 1 so you take only odd coefficients C 1, C 3, C 5 up to C 2 k plus 1. So in this case here C 0, C 2, C 2 k.

(Refer Slide Time: 14:03)

So when it is even, even case I can write all these things C 2 k up to C 2 in terms of C 0. So you have C 0 coefficient and a polynomial of degree 2 k, some polynomial, okay. Polynomial of degree 2 k. So here in this case here also from the recurrence formula, so if you have n is odd, C 1 you will not be able to evaluate, get it. C 3 you can get in terms of C 1, C 5 in terms of C 1 up to C 2 k plus 1 in terms of 1.

And once you substitute you get C 1 times a polynomial of degree 2 k plus 1. This is what you get. So what do we do is to derive the formula for P n, instead of writing C 2 in terms of C 0 or here C 1 in terms of or C 3 in terms of C 1. We do the reverse way. So we consider C 2 k or C 2 k plus 1. I do not find this one, okay. What we do is I try to keep this as arbitrary constant. C 2 k minus 2 I write in terms of C 2 k.

Similarly going backwards you see that C 2 will be in terms of C 2 k. C 0 will be in terms of C 2 k. So finally instead of C 0 you will get C 2 k. Again we will get a polynomial that is also one way of doing it, okay.

(Refer Slide Time: 15:28)

Property: $P_n(x)$, $n \in \mathbb{Z}$ is a bounded solution for the Legendre equation $(1-x^2)y'' - 2xy' + n(n+1)y = 0$, $-K < x < 1$

New formula for $P_n(x)$:

Recurrence relation: $(n+1)(n+2) c_{n+2} = -(x-n)(x+n+1) c_n$, $n \geq 0$

\Rightarrow $n = \text{even} : 2k$
 $n = \text{odd} : (2k+1)$

$c_{2k} = \binom{n}{2k} c_0$ c_0, c_2, \dots, c_{2k} (polynomial)
 $c_1, c_3, c_5, \dots, c_{2k+1}$ c_1 (polynomial)

We do the same thing. So you write instead of finding this C_{2k+1} from this recurrence relation you try to do it reverse way. You keep this $2k+1$ as it is and then C_{2k-1} you write in terms of C_{2k+1} . C_5 also in terms of this, C_3 will be in terms of $2k+1$.

Similarly C_1 in terms of $2k+1$. Then once you substitute back the polynomial solution will be $2k+1$ into this polynomial degree, something like similar you will get it, okay. Now you fix this constant which depends only on this $2k$ or $2k+1$ which is n , okay.

(Refer Slide Time: 16:13)

Property: $P_n(x)$, $n \in \mathbb{Z}$ is a bounded solution for the Legendre equation $(1-x^2)y'' - 2xy' + n(n+1)y = 0$, $-K < x < 1$

New formula for $P_n(x)$:

Recurrence relation: $(n+1)(n+2) c_{n+2} = -(x-n)(x+n+1) c_n$, $n \geq 0$

\Rightarrow $n = \text{even} : 2k$
 $n = \text{odd} : (2k+1)$

$c_{2k} = \binom{n}{2k} c_0$ c_0, c_2, \dots, c_{2k} (polynomial)
 $c_1, c_3, c_5, \dots, c_{2k+1}$ c_1 (polynomial)

If I can give you this polynomial that is this is the polynomial of degree $2k$ that means equal to n . This is your C_n . If I give my C_n which is the coefficient of x power n in this

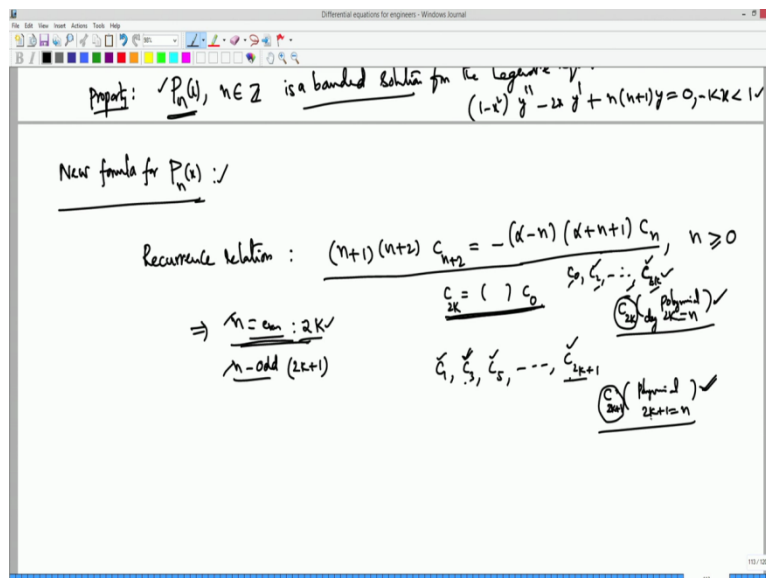

polynomial, okay, so that I hope I have to give you exactly what is P_n . I will tell you because you know that P_n is a polynomial of degree n with some coefficient. Same coefficient if you give here because from the Rodrigues' formula you know what is the P_n of x .

The coefficient of x power n is something which you know from the Rodrigues' formula. The same coefficient you also assign here as a C_n then what you get is a polynomial solution with the same x power n coefficient, okay. Polynomial solution of the Legendre equation with same coefficient as in the P_n . So if you know that P_n is the solution and this new polynomial is also a solution with the same x power n coefficient.

And then if they are the solutions of the Legendre homogeneous equation which is Legendre equation second order homogeneous equation. So their difference if you take these two polynomial differences what happens? With the same x power n coefficient when you take the difference it will become n minus 1th degree polynomial solution, okay, for the same Legendre equation which is having alpha equal to n .

But you know that you do not have n minus 1th degree polynomial solution for Legendre equation alpha equal to n . And then it has to be 0. It has to be series but it is not series here. And because it is a homogeneous equations there is no other solution except the trivial solution, 0 is a solution. That means the P_n and this new polynomial should be same, okay, either this or this. This is n , okay, and n is odd this is this.

(Refer Slide Time: 17:58)

So we will see that will give you a formula for P_n , okay. That is the idea. So let us work out. So you take this one. So instead of writing C_{n+2} so we normally do like this, alpha

minus n , $\alpha + n + 1$ divided by $n + 1$, $n + 2$ C_n . This is what we normally do, okay, n is from 0, 1, 2 up to. This is what we do but instead we reverse this thing. So if you want reverse, this you want C_n . you want this to be rather you write reverse, it is reverse way.

C_n equal to $n + 1$, $n + 2$ divided by, sorry how minus $\alpha - n$, $\alpha + n + 1$ into C_{n+2} , n is from 0, 1, 2 onwards, okay. N is fixed either even or odd so what we see is wherever you start, okay, so you will not be able to get C_0 and C_1 , right? So it should start from either 2, 3 onwards, okay. So that means this I can write n equal to $n - 2$, if you put it, okay, and this will become minus n equal to $n - 2$, okay.

So if I do this, this side will be C_n . Everything in terms of lesser coefficients will be in terms of C_n . So n equal to $n - 2$, so this is going to be $n - 1$, n equal to $n - 2$ n divided by $\alpha - n - 2$ that is plus 2 into $\alpha + n - 1$, $n - 2 + 1$. So this is what you have, into C_n , okay. Into C_n , n is from 0, 1, 2, 3 onwards.

(Refer Slide Time: 19:53)

$$C_{n+2} = -\frac{(x-n)(x+n+1)}{(n+1)(n+2)} C_n, \quad n=0,1,2, \dots$$

$$C_n = -\frac{(n+1)(n+2)}{(x-n)(x+n+1)} C_{n+2}, \quad n=0,1,2, \dots$$

$$C_{n-2} = -\frac{(n-1)n}{(x-n+2)(x+n-1)} C_n, \quad n=0,1,2, \dots$$

So once you fix your n you can write lower coefficients in terms of C_n , fixed n , okay. So we use this C_n . This C_n is the coefficient of, so if you try to get all this C_{n-2} , C_{n-4} and so on, let us see what is my C_{n-4} ? This is going to be minus $n - 2$ here, so $n - 3$, $n - 2$, okay, divided by C_{n-2} . This is going to be $\alpha - n - 2$, okay.

$\alpha - n + 4$ and this is going to be $\alpha + n - 4$, $n - 4$ is $n - 3$. So like this you can go on. You can get C_{n+2} , so you already know C_{n-2} from the

earlier expression that you can put it. So you can get C_{n-4} in terms of C_n , like that you can get, okay.

(Refer Slide Time: 20:58)

$$C_{n+2} = -\frac{(n+1)(n+2)}{(k-n)(k+n+1)} C_n$$

$$C_n = -\frac{(n+1)(n+2)}{(k-n)(k+n+1)} C_{n+2}, \quad n=0,1,2,\dots$$

$$C_{n-2} = -\frac{(n-1)n}{(k-n+2)(k+n-1)} C_n, \quad n=0,1,2,\dots$$

$$C_{n-4} = -\frac{(n-3)(n-2)}{(k-n+4)(k+n-3)} C_{n-2}$$

So once you substitute all these C_0 , if n is even you can get C_0, C_2, C_4 up to C_{n-2} . all these things are in terms of C_n . If C_n is odd you can get C_1, C_3, C_5 up to C_{n-2} , okay. Yes C_{n-2} . So if n is odd you are going up to, so C_1 you are not able to calculate, right, normally. So C_3, C_5 , so n is odd means so minimum n equal to 3 onwards, right, n equal to 3. So all these things you are writing in terms of C_n in the odd case, okay.

So once you substitute back what you get is C_0 in terms of C_n . Some C_n will be common in both the cases on the polynomial of degree n . This is what you have. So this C_n I fix as, now I know why my P_n is, what is my P_n of x from the Rodrigues' formula is 1 by 2 power n into n factorial, n derivatives of x square minus 1 power n , okay. And this one we have already seen that coefficient of x power n is, what is the coefficient of x power n ?

Coefficient of x power you can actually get it as 2^n factorial divided by coefficient of x power n in P_n of x is actually equal to 2^n factorial divided by 2^n into n factorial square. This is not difficult to see. If you actually differentiate x power 2^n so you have x power 2^n as the polynomial that you are differentiating n times, right? So if you differentiate n times this becomes what happens?

So how do you see this? Coefficient as actually coefficient of x power n in P_n is equal to 1 by 2^n into n factorial which I write here. So n derivatives of x power 2^n is $2^n, 2^n$

minus 1 up to 2 n minus, if you do twice you get into n minus 1. So you will get up to n minus 1, right, n plus 1 rather. Up to n plus 1 you will get, right?

(Refer Slide Time: 23:52)

Handwritten notes on a whiteboard:

$$C_{n-2} = \frac{-(n-1)n}{(k-n+2)(k+n-1)} C_n, \quad n=0,1,2,\dots$$

$$C_{n-4} = \frac{-(n-3)(n-2)}{(k-n+4)(k+n-3)} C_{n-2}$$

$$p_n(x) = \frac{1}{2^n n!} \frac{d^n}{dx^n} \left((x-1)^n \right) \quad \frac{d^n}{dx^n} (x^n)$$

Annotations on the right side of the whiteboard:

- C_n (checked)
- $C_0, C_2, C_4, \dots, C_{2n}$ (underlined)
- C_n (underlined)
- $C_1, C_3, C_5, \dots, C_{2n-1}$ (underlined)
- C_n [Polynomial deg n] (in brackets)

$$\text{Coeff of } x^n \text{ in } p_n(x) = \frac{(2n)!}{2^n (n!)^2}$$

$$\text{Coeff of } x^n \text{ in } p_n(x) = \frac{1}{2^n n!} 2n(2n-1)\dots(n+1)$$

If you do x power 2 n, n times, okay, then what you get is x power n coefficient, okay. So that is the x power n coefficient, this terms will be simply this and this is equal to I have 2 n, 2 n minus 1. So if you divide and multiply n factorial so what you are getting is 2 n factorial divided by 2 power n into n factorial square. So like that, you can get this. So you use this as your C n, okay. So let C n be 2 n factorial divided by 2 power n into n factorial square. If I choose this what happens to my C n minus 2, C n minus 4 and so on, okay.

(Refer Slide Time: 24:46)

Handwritten notes on a whiteboard (continued from previous slide):

$$\text{Coeff of } x^n \text{ in } p_n(x) = \frac{(2n)!}{2^n (n!)^2} = \frac{1}{2^n n!} 2n(2n-1)\dots(n+1) = \frac{2n!}{2^n (n!)^2} \checkmark$$

$$\text{Let } C_n = \frac{2n!}{n!}$$

So you can write first what is your C_{n-2} ? C_{n-2} is $n-3$ into $n-2$ into $n-1$ into n divided by, now alpha is actually n , okay. Now you fix your alpha. Alpha is n , n is $n-3$ plus 4. So you have 4 times, okay, not 4 so I think 2, okay. You fix it here so alpha equal to n you have 2 into 2 $n-1$ into alpha into C_n . So what is C_n ? C_n is now I fixed it which is 2^n factorial divided by 2^n into n factorial square.

So this is equal to so you see that 2^n , 2^n minus 1 goes. So you have 2^n , 2^n minus, so you can rewrite minus n into $n-1$, 2^n into 2^n minus 1 and 2^n minus 2 factorial. This I am writing like that and we have 2 into 2 $n-1$ into 2^n into n factorial into n factorial. If you write this is equal to, so n into $n-1$ if you remove denominator this n factorial becomes, if I cancel this here what I am left with is $n-2$ factorial, okay. And we have 2^n minus 1, 2^n minus 1 goes and here n you cancel here one n .

So you get $n-1$ factorial. What you left with is 2^n minus 2 factorial plus, write 2^n minus 2 factorial into 2^n and 2^n goes here. That is what you have, okay. That is your C_{n-2} .

(Refer Slide Time: 26:49)

The image shows a digital whiteboard with the following handwritten mathematical steps:

$$\text{Coeff of } x^n \text{ in } f_n(x) = \frac{1}{2^n n!} \cdot 2^n (2n-1) \cdots (n+1)n! = \frac{2n!}{2^n (n!)^2}$$

$$\text{Let } C_n = \frac{2n!}{2^n (n!)^2}$$

$$C_{n-2} = \frac{(n-1)n \cdot 2n!}{2 \cdot (2n-1) \cdot 2^n (n!)^2} = \frac{\cancel{2n!} \cdot (n-1)n \cdot \cancel{2n!} (2n-2)!}{2 \cdot (2n-1) \cdot 2^n \cdot n! \cdot n!}$$

$$C_{n-2} = \frac{(2n-2)!}{2^n (n-1)! (n-2)!}$$

Now you get your C_{n-4} . C_{n-4} is $n-3$, $n-2$, okay. Minus n minus 3, $n-2$ divided by, alpha is now we fixed here alpha as n , so $n-3$ plus 4, 4 into 2^n minus 3. Now what you get is C_{n-2} . So C_{n-2} we already know what it is, right? C_{n-2} is 2^n minus 2 factorial divided by 2^n , $n-1$ factorial, $n-2$ factorial. If you simply calculate it now, okay.

You already calculated C_{n-2} which you put it here so this will become, so what you do is $n-2$, $n-3$ you cancel here, okay. Of course you have a minus of this, right? So it is a minus minus plus here. So in this case what you have is in the denominator if you cancel here so it will become $n-4$ factorial. So this you can rewrite 2^{n-2} , 2^{n-3} , okay, and then 2^{n-4} factorial you can write.

So 2^{n-3} will go, okay, and here $n-1$. So this 2^{n-1} this 2 you can take it out here, write $n-1$. This you cancel here it still become $n-2$ factorial, 2^n as it is, 2^2 goes, you have 1 into 2. So you have 2 factorial rather, okay, it becomes like that.

(Refer Slide Time: 28:37)

The image shows a software window titled "Differential equations for engineers - Windows Journal" containing handwritten mathematical work. At the top, $2^{(n)!}$ is written. Below it, the derivation for C_{n-2} is shown:

$$C_{n-2} = \frac{(n-1)n}{2 \cdot (2n-1)} \frac{2n!}{2^n (n!)^2} = \frac{\cancel{n(n-1)} \cancel{2} (2n-2)!}{2 \cdot (2n-1) 2^n \cdot \cancel{n} \cdot \cancel{n}}$$

$$C_{n-2} = \frac{(2n-2)!}{2^n (n-1)! (n-2)!}$$

Below this, the derivation for C_{n-4} is shown:

$$C_{n-4} = \frac{+(n-3)(n-4)}{2 \cdot (2n-3)} \frac{(n-1)(2n-2)(2n-4)!}{2^n (n-2)! (n-2)!}$$

$$= \frac{2!}{2! 2^n (n-2)! (n-4)!}$$

Then what is in the numerator? So we simply have 2^{n-4} factorial. This is my C_{n-4} , okay. So like this if you go on by induction you can write C_{n-2k} , how long you can go if n is even? If n is even so let us say $2k$, I can go up to k equal to n by 2, okay. If n is odd I can go only up to C_1 . That means if n is odd you simply calculate n by 2 integral part of it, okay.

If it is n is 5, 5 by 2, so only 2. Integral part is that is 2, okay, like that. So you take like this if you write like this, this is the integral part. Bracket of n by 2. So k will go up to, k is from 0, 1, 2 up to n by 2 as an integral part, okay, (inti) (inti) integer part, okay, integer part is this.

(Refer Slide Time: 29:49)

The image shows a software window titled "Differential equations for engineers - Windows Journal". The handwritten content is as follows:

$$C_{n-4} = \frac{+ (n-3)(n-4) \cancel{2} (n-1)(2n-2)(2n-4)!}{2^4 (2n-3)! 2^n (n-2)! (n-4)!}$$

$$C_{n-4} = \frac{(2n-4)!}{2! 2^n (n-2)! (n-4)!}$$

$C_{n-2k} =$
 $k=0, 1, \dots, \lfloor \frac{n}{2} \rfloor$
integer part $\lfloor \frac{n}{2} \rfloor$

So by induction you can write 2^n minus. So you have a minus so when it is n minus 2 into 2 you have plus, so you have minus 1 power k , 2^{n-2k} factorial divided by, this is going to be k factorial, 2^n , n minus k factorial and n minus $2k$ factorial. This is what you will get, okay. Now simply your solutions because I have already explained if you take C_n which is same as the coefficient of P_n , it has to be a same Legendre polynomial.

So the P_n , okay, so let us say simply if n is even, okay, n is even what happens to your y_1 of x now? y_1 of x is C_0 , C_1 , okay. Everything in terms of C_k , okay. And C_k I fixed now this number, whatever the coefficient of P_n . Then you simply have n is even so n equal to $2k$, okay.

(Refer Slide Time: 31:00)

The image shows a software window titled "Differential equations for engineers - Windows Journal". The handwritten content is as follows:

$$C_{n-4} = \frac{(2n-4)!}{2! 2^n (n-2)! (n-4)!}$$

$$C_{n-2k} = \frac{(-1)^k (2n-2k)!}{k! 2^n (n-k)! (n-2k)!}$$
 $k=0, 1, \dots, \lfloor \frac{n}{2} \rfloor$
integer part $\lfloor \frac{n}{2} \rfloor$

$\Rightarrow \frac{n}{2} \text{ even}$
 $y_1(x) = \sum_{n=0}^{\lfloor \frac{n}{2} \rfloor} C_{n-2k} x^{n-2k}$

So if you do that so k is from 0 to n by 2. If n is even no problem, integer part also is n by 2, minus 1 power k, 2 n minus 2 k factorial divided by k factorial 2 power n, n minus k factorial, n minus 2 k factorial. This is what you will get into x power, if k equal to 0, what is this? If k 0 x power n, n minus every time. So when k equal to 0, x power n coefficient.

If k equal to 1, x power n minus 2 coefficient. So every time you have 2 k. So x power n minus 2 k. So this is your polynomial, okay. The way you fixed it when k equal to 0 this is exactly the coefficient of y 1 of x. Coefficient of x power n in y 1 of x is actually equal to coefficient of P n x power n in P n of x from the Rodrigues' formula, okay.

(Refer Slide Time: 32:11)

The image shows a whiteboard with the following handwritten content:

$$C_{n-k} = \frac{(2n-k)!}{2! \cdot 2^n \cdot (n-k)! \cdot (n-k)!}$$

$$C_{n-2k} = \frac{(-1)^k (2n-2k)!}{k! \cdot 2^n \cdot (n-k)! \cdot (n-2k)!} \quad k=0, 1, 2, \dots, \left\lfloor \frac{n}{2} \right\rfloor$$

integer part $\left\lfloor \frac{n}{2} \right\rfloor$

$$\Rightarrow \text{the even } y_1(x) = \sum_{k=0}^{\left\lfloor \frac{n}{2} \right\rfloor} \frac{(-1)^k (2n-2k)!}{k! \cdot 2^n \cdot (n-k)! \cdot (n-2k)!} \cdot x^{n-2k}$$

$$\text{Coeff of } x^n \text{ in } y_1(x) = \text{Coeff of } x^n \text{ in } P_n(x)$$

Both are solutions. These two are solutions. Y 1, P n x are solutions of Legendre equation. Y 1 x minus P n x is also solution of Legendre equation. What is this from this left hand side is now? If you have the same coefficient and you take the difference this will be n minus 1th degree. Equation with alpha equal to n. Is it possible? N minus 1th degree polynomial solution you will not get for the Legendre equation when alpha equal to n unless it is 0, okay.

That means it has to be 0 because either you have a series solution or a polynomial solution of degree n. Other solution is trivial solution 0, okay. Trivial solution is 0 so this has to be 0, okay. So that implies y 1 of x is nothing but your P n of x. So you have a formula. Now I can replace with y 1 as P n of x, okay. This is what if n is even.

(Refer Slide Time: 33:17)

The image shows a handwritten derivation in a software window titled "Differential equations for engineers - Windows Journal". The derivation is as follows:

$$C_{n-2k} = \frac{(-1)^k (2n-2k)!}{k! 2^n (n-k)! (n-2k)!} \quad k=0, 1, \dots, \lfloor \frac{n}{2} \rfloor$$

$$\Rightarrow \text{if } n \text{ even } \quad P_n(x) = \sum_{k=0}^{\lfloor \frac{n}{2} \rfloor} \frac{(-1)^k (2n-2k)!}{k! 2^n (n-k)! (n-2k)!} x^{n-2k}$$

Coeff of x^n in $y_1(x) =$ coeff of x^n in $P_n(x)$.

$(n-1)$ degree $= y_1(x) - P_n(x)$ is soln of Legendre equation with $\alpha=n$.

$$y_1(x) - P_n(x) = 0 \Rightarrow y_1(x) = P_n(x) \checkmark$$

So if n is odd also it is the same thing. So n is anything. If n is odd it will repeat the same thing, $2k + 1$. What you can do is you can go up to $2k + 1$ minus 2 that is the first coefficient, okay, when you write this. $n - n$ is $2k + 1$, okay. And put k equal to 0, n is odd that is the coefficient. Every time 2 minus so x power $n - 2$, $n - 4$, you come up to x , okay, because this is the coefficient of C_1 when it is odd. And finally so that is why you put this integral part n by 2.

So you do not make if n is odd, n by 2 so that is if it is n is 5, 5 by 2 is simply 2. So you will have two terms $5 - 3$, $3 - 2$, so 1. So you have two more terms. So you go up to C_1 , C_3 , C_5 . C_1 coefficient is x , x cube, x power 5. So that is the polynomial, okay. So in any case this is what is the case, okay. For any natural numbers you have P_n as this. So this is the formula you can also use directly to calculate this Legendre polynomials, okay.

(Refer Slide Time: 34:33)

$$C_{n-k} = \frac{(-1)^k}{k! 2^n (n-k)! (n-k)!}$$

$$C_{n-2k} = \frac{(-1)^k (2n-2k)!}{k! 2^n (n-k)! (n-2k)!} \quad k=0, 1, \dots, \left[\frac{n}{2}\right]$$

integer part $\left[\frac{n}{2}\right]$

$$\Rightarrow \text{For any } n \in \mathbb{N}, P_n(x) = \sum_{k=0}^{\left[\frac{n}{2}\right]} \frac{(-1)^k (2n-2k)!}{k! 2^n (n-k)! (n-2k)!} x^{n-2k} \quad \checkmark$$

Coeff of x^n in $y_1(x) =$ Coeff of x^n in $P_n(x)$.

$(n-1)$ degree $= y_1(x) - P_n(x)$ is soln soln of Legendre equation with $k=n$.

$$y_1(x) - P_n(x) = 0 \Rightarrow y_1(x) = P_n(x) \quad \checkmark$$

And one more property I give you now. It is just you have see that 1 I can write it as P_0 of x , x I can write it as P_1 of x , okay, Legendre polynomial, x square, okay. So n equal to 1 it is true, n equal to 0 it is true, n equal to 1 it is true. This polynomial $1 \times I$ can write in terms of P_1 , okay. What if I write x square? what is x square? So now what happens to x square?

So let us assume that x power n minus 1 is a linear combination of P_0, P_1, \dots, P_{n-1} . So you see that 1 is linear combination of P_0, x power 0, okay. x is linear combination of P_1 that is actually x , right? So it is actually linear combination is 0 into 1 plus 1 into P_1 , right? So that is again actually this is a linear combination of these two.

(Refer Slide Time: 35:48)

$$y_1(x) - P_n(x) = 0 \Rightarrow y_1(x) = P_n(x) \quad \checkmark$$

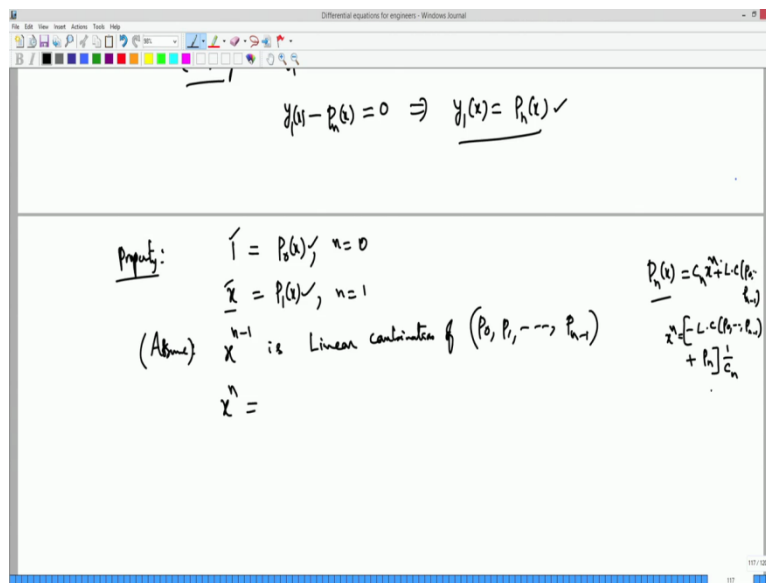

Property:

- $\hat{1} = P_0(x), n=0$
- $\hat{x} = P_1(x), n=1$
- x^{n-1} is Linear combination of $(P_0, P_1, \dots, P_{n-1})$

So this you assume by induction we can assume this. If you assume this we can now say x power n . What is x power n ? How do I calculate this x power n ? So you know that P_n is a polynomial. P_n of x is a polynomial and this is having x power n coefficient.

So coefficient also you know some and remaining x you already assumed that up to x power n are linear combination of P_0, P_1, \dots, P_{n-1} , okay. And so you have x power n is simply linear combination of P_0 minus of linear combination of P_0, P_1, \dots, P_{n-1} , okay, plus P_n . This whole thing divided by 1 by C_n , right?

(Refer Slide Time: 36:35)

So what is this one actually? This is simply linear combination of P_0, P_1, P_n , okay. So you can write like this. So x power n you can say simply P_n by C_n , okay, into C_n by C_n plus I should say minus, minus of 1 by C_n times linear combination of P_0, P_1 up to P_{n-1} . So this is nothing but linear combination of P_0, P_1, P_n because P_{n-1} , okay. So that is it. So this implies x power n is a linear combination of this. This is the proof, okay. It implies this is what you get.

So that means any polynomial of degree n is a linear combination of P_0, P_1 up to P_n of x , okay. And these are all functions of x , these polynomials, okay. So this is the property 3. So I think there are many more properties of this polynomial which are really useful. So most important property is the orthogonal property which I have derived in the last video. So this is enough.

(Refer Slide Time: 38:05)

Properties:
 $\hat{1} = P_0(x), n=0$
 $\hat{x} = P_1(x), n=1$
 (Abuse) x^{n-1} is Linear combination of $(P_0, P_1, \dots, P_{n-1})$
 $x^n = \frac{P_n}{c_n} - \frac{1}{c_n} (\text{L.C. of } P_0, P_1, \dots, P_{n-1})$
 $\Rightarrow x^n = \text{L.C. of } (P_0, P_1, \dots, P_n) \checkmark$
 $\Rightarrow \text{Any polynomial of degree 'n' is a L.C. of } (P_0, P_1, \dots, P_n)$

$P_n(x) = c_n x^n + \text{L.C. of } (P_0, \dots, P_{n-1})$
 $x^n = \frac{P_n}{c_n} - \frac{1}{c_n} (\text{L.C. of } (P_0, \dots, P_{n-1}))$
 $= \text{L.C. of } (P_0, \dots, P_n)$

And move on to solve other equations when 0 is regular singular point, okay. So we have applied the power series method to the Legendre equation when 0 is an ordinary point, okay. So now we can look into some second order linear homogeneous equations where 0 is actually singular point, singular but it is a regular singular point. So in the next video we will do this Frobenius method to solve the second order homogeneous equation with 0 being (re) singular point but a regular one, okay.

So you know the definition of a regular singular point. So we will give the method. So such an equation if you have second order homogeneous equation with 0 being the regular singular point, so either this side or that side, x greater than 0 or x less than 0 we can find solutions. That is the method of Frobenius. So we will give that in the next video.
