Frobenius Method of Solutions (Continued)

We were looking at case of solving a differential equation of second order with variable coefficients by Frobenius method. So we have already seen we were doing one example where the indicial equation has two roots, first root will give you one solution. Second root when you look at the difference between these two roots k_1 and k_2 and their difference will be integer which is non zero (dif) integer.

So we have given first solution, in this video we will give you a second solution. How to get the second solution? There we have already seen what kind of form it takes for the second solution. So we will proceed how to get that second solution. So this is your second solution and the solution is of this form y_2 is A or some arbitrary constant times $y_1 \log x$ and x power this k_2 , so k_2 is this. So finally you get this form.

(Refer Slide Time: 01:18)

The image shows a whiteboard with handwritten text and a mathematical equation. The text reads: "Let $k = k_2 = -2$, the second solution is of the form". Below this, the equation is written as:
$$y_2(x) = A y_1(x) \log x + x^{k_2} \sum_{n=0}^{\infty} d_n x^n = A y_1(x) \log x + x^{-2} \sum_{n=0}^{\infty} d_n x^n$$
 A horizontal line is drawn under the equation. To the right of the line, it says: "A, d_n are constants to be found."

So y_2 is A times some arbitrary constant y_1 which. You already wrote it for k equal to k_1 which is $1 \log x$ plus x power, k_2 is minus 2 and we have a power series representation $d_n x^n$ and d_n s are arbitrary constants along with A . So these are constants we have to find out by simply substituting into the equation. So the equation is given here so that is $x^2 y''$. So this is your equation. So we will just substitute into this equation for y_2 .

So for y you replace this y^2 so calculate y^2 of x . So I will use black. So y^2 is A times y^2 dash, y^2 dash you calculate so you get $y^1 x$ by x . So that I am differentiated $\log x$, okay, and then plus $A \log x y^1$ dash of x plus here. So you simply differentiate once that is n is from 0 to infinity $d_n x$ power n minus 2, okay. So if you differentiate this is going to be n minus 2 times x power n minus 1. This is what you will get because k^2 is integer.

(Refer Slide Time: 02:53)

Let $k = k_2 = -1$

$$y(x) = A y(x) \log x + x^k \sum_{n=0}^{\infty} d_n x^n = A y(x) \log x + x^{-1} \sum_{n=0}^{\infty} d_n x^n$$

A, d_n are constants to be found.

$$y'(x) = \frac{A}{x} y(x) + A \log x y'(x) + \sum_{n=0}^{\infty} d_n x^{n-1} (n-2)$$

So once you differentiate you will see that n equal to 0. So I think you cannot do this. So let us differentiate. So if you look at this series that is $d_0 x$ power minus 2 plus $d_1 x$ power minus 1 plus $d_2 x$ power 0 plus $d_3 x$ and so on. So $d_4 x$ square and so on, okay. So or you can differentiate as a two functions, okay.

As if this is one function and the series is another function so differentiate this once so you have x power minus 2, this will give me n is from 1 to infinity, n into $n d_n x$ power n minus 1, okay. Then plus keep the series as it is then differentiate the other part that is x power minus 2. What is the derivative of 1 by x square? 1 by x square derivative is minus 2 by x cube, okay, minus 2 by x cube.

(Refer Slide Time: 04:16)

Let $k = k_1 = -2$, we have

$$y(x) = A y(x) \log x + x^{-2} \sum_{n=0}^{\infty} d_n x^n = A y(x) \log x + x^{-2} \sum_{n=0}^{\infty} d_n x^n$$

A, d_n are constants to be found.

$$y_1'(x) = \frac{A}{x} y(x) + A \log x y_1'(x) + x^{-2} \sum_{n=1}^{\infty} n d_n x^{n-1} + \sum_{n=0}^{\infty} d_n x^{-3}$$

$\frac{1}{x}$
 $-\frac{2}{3} x^{-3}$

So you have minus 2 by x cube. So this is what is your y 2 dash. And you need y 2 double dash. So second derivative will be A by x square y 1 x plus A by x y 1 dash of x, so I differentiated this term one more time and it will be the second term you have A by x y 1 dash of x plus A log x y 1 double dash of x plus again this will give you so one more derivative here.

So if you do that x minus 2 and this is from n is from 2 to infinity, n into n minus 1 d n x power n minus 2. So I differentiated the series first. I had to differentiate x power minus of that will give me minus 2 by x cube where this n is from 1 to infinity, n d n x power n minus 1, okay.

(Refer Slide Time: 05:31)

Let $k = k_1 = -2$, we have

$$y(x) = A y(x) \log x + x^{-2} \sum_{n=0}^{\infty} d_n x^n = A y(x) \log x + x^{-2} \sum_{n=0}^{\infty} d_n x^n$$

A, d_n are constants to be found.

$$y_1'(x) = \frac{A}{x} y(x) + A \log x y_1'(x) + x^{-2} \sum_{n=1}^{\infty} n d_n x^{n-1} - \frac{2}{x^3} \sum_{n=0}^{\infty} d_n x^n$$

$$y_2''(x) = -\frac{A}{x^2} y(x) + \frac{A}{x} y_1'(x) + \frac{A}{x} y_1'(x) + A \log x y_2''(x) + x^{-2} \sum_{n=2}^{\infty} n(n-1) d_n x^{n-2} - \frac{2}{x^3} \sum_{n=0}^{\infty} n d_n x^{n-1}$$

And then now you differentiate the last term so that will give you minus 2 by x cube. If you differentiate this series n is from 1 to infinity, n d n x power n minus 1. And then you differentiate 2 by x cube that will give me, so derivative of 1 by x cube, 1 by x cube derivative is actually x power 5, right? So you have 3 x power 4 I guess. You get x power 4, right? So you have this is x power 6, x is minus so we have 3 x square.

So minus 3 by x power 4, okay. That is how minus 3 into 2, so we have 6 by x power 4. So we have minus minus plus, so it is going to be plus and we have this n is from 0 to infinity, d n x power n. So this is what is your y double dash.

(Refer Slide Time: 06:46)

Let $k = k_1 = -2$

$$y(x) = A y(x) \log x + x^k \sum_{n=0}^{\infty} d_n x^n = A y(x) \log x + x^{-2} \sum_{n=0}^{\infty} d_n x^n$$

A, d_n are constants to be found.

$$y'(x) = \frac{A}{x} y(x) + A \log x y'(x) + x^{-2} \sum_{n=1}^{\infty} n d_n x^{n-1} - \frac{2}{x^3} \sum_{n=0}^{\infty} d_n x^n \quad \frac{A}{x} \left(\frac{1}{x}\right) = \frac{-2}{x^2}$$

$$y''(x) = -\frac{A}{x^2} y(x) + \frac{A}{x} y'(x) + \frac{A}{x} y'(x) + A \log x y''(x) + x^{-2} \sum_{n=2}^{\infty} n(n-1) d_n x^{n-2} - \frac{2}{x^3} \sum_{n=0}^{\infty} n d_n x^{n-1} - \frac{2}{x^3} \sum_{n=1}^{\infty} n d_n x^{n-1} + \frac{6}{x^4} \sum_{n=0}^{\infty} d_n x^n$$

Now substitute this y 2 here, y 2 dash and y 2 double dash substitute into the equation. Given equation is if you substitute so you have x square into y double dash first of all. First term is x square into y double dash. So if you multiply you need this x square. So I multiply here itself x square y double dash will be you remove x square here and you have x here, x goes and you have x here, A by x, so x into A and you have x square and this goes and here you have simply x, okay. And then here again x and here x square.

(Refer Slide Time: 07:43)

The whiteboard shows the following equations:

$$y_2'(x) = \frac{A y_1(x) + A \log x y_1'(x) + x^{-2} \sum_{n=1}^{\infty} n d_n x^{n-1} - \frac{2}{x^2} \sum_{n=0}^{\infty} d_n x^n}{x} \quad \frac{1}{x^2} = \frac{-1}{x^2}$$

$$x^2 y_2''(x) = -A y_1(x) + x^2 A y_1'(x) + 2x A y_1'(x) + x^2 A \log x y_1''(x) + \sum_{n=2}^{\infty} n(n-1) d_n x^{n-2} - \frac{2}{x} \sum_{n=0}^{\infty} n d_n x^{n-1}$$

$$- \frac{2}{x} \sum_{n=1}^{\infty} n d_n x^{n-1} + \frac{6}{2} \sum_{n=0}^{\infty} d_n x^n \quad \checkmark$$

This is how you will get x square y double dash. So second term is 2 x plus x square y dash. So that is my second term of the given differential equation. So this if you do so for this you need x y dash, x y 2 dash and x square y 2 dash. So so let me rewrite again.

So you have x y 2 dash of x is, from y 2 dash you can get it as A y 1 A x log x y 1 dash of x plus x power minus 1, sigma n is from 1 to infinity, n d n x power n minus 1, minus 2 by x square, sigma n is from 0 to infinity, d n x power n. And this is by x y 2 y dash. So you need 2 x y dash, so multiply 2 so it will be 4. So this is what you have. So what you need is x square y 2 dash.

(Refer Slide Time: 09:04)

The whiteboard shows the following equations:

$$y_2'(x) = \frac{A y_1(x) + A \log x y_1'(x) + x \sum_{n=1}^{\infty} n d_n x^{n-1} - \frac{2}{x^2} \sum_{n=0}^{\infty} d_n x^n}{x} \quad \frac{1}{x^2} = \frac{-1}{x^2}$$

$$x^2 y_2''(x) = -A y_1(x) + x^2 A y_1'(x) + 2x A y_1'(x) + x^2 A \log x y_1''(x) + \sum_{n=2}^{\infty} n(n-1) d_n x^{n-2} - \frac{2}{x} \sum_{n=0}^{\infty} n d_n x^{n-1}$$

$$- \frac{2}{x} \sum_{n=1}^{\infty} n d_n x^{n-1} + \frac{6}{2} \sum_{n=0}^{\infty} d_n x^n \quad \checkmark$$

$$2x y_2'(x) = 2A y_1(x) + 2A x \log x y_1'(x) + 2x \sum_{n=1}^{\infty} n d_n x^{n-1} - \frac{4}{x} \sum_{n=0}^{\infty} d_n x^n$$

$$x^2 y_2''(x) =$$

Now you multiply x square to this y 2 dash. So that will give you A x y 1 x plus A x square log x y 1 dash x plus you get simply the series n d n x power n minus 1 minus 2 by x, sigma n is from 0 to infinity, d n x power n. So these are the three things you have to substitute. So these three and then for y into the equation. So given equation is x square y double dash plus x.

(Refer Slide Time: 09:52)

The image shows a digital whiteboard with the following handwritten mathematical work:

$$y_2'(x) = \frac{A y_1(x)}{x} + A \log x y_1'(x) + x^{-2} \sum_{n=1}^{\infty} n d_n x^{n-1} - \frac{2}{x^3} \sum_{n=0}^{\infty} d_n x^n \quad \checkmark \quad \frac{1}{x} \left(\frac{-3}{x} \right)$$

$$x^2 y_2''(x) = -A y_1(x) + x^2 A y_1'(x) + x A y_1'(x) + x^2 A \log x y_1''(x) + \sum_{n=2}^{\infty} n(n-1) d_n x^{n-2} - \frac{2}{x} \sum_{n=0}^{\infty} n d_n x^{n-1}$$

$$- \frac{2}{x} \sum_{n=1}^{\infty} n d_n x^{n-1} + \frac{6}{2} \sum_{n=0}^{\infty} d_n x^n \quad \checkmark$$

$$2 x y_2'(x) = 2 A y_1(x) + 2 A x \log x y_1'(x) + 2 x \sum_{n=1}^{\infty} n d_n x^{n-1} - \frac{4}{x} \sum_{n=0}^{\infty} d_n x^n \quad \checkmark$$

$$x^2 y_2''(x) = A x y_1(x) + A x^2 \log x y_1'(x) + \sum_{n=1}^{\infty} n d_n x^{n-1} - \frac{2}{x} \sum_{n=0}^{\infty} d_n x^n \quad \checkmark$$

$$x^2 y_2'' + x$$

So if you want solution y 2 so x 2 y double dash, x into 2 plus x square is 2 x plus x square into y 2 dash minus 2 times y 2 has to be 0. So this is the given equation, okay. The given equation is substitute y 2 dash and y 2 double dash and y 2, okay, from all this. So x square y double dash if you see you can take this one and bring it here. So you substitute here the whole thing if you replace so what you get? So you get minus A (())(10:29) so y 1 x plus x here y 1 dash.

So you have 2 x A y 1 dash of x. So second and third term together is that plus A x square log x, okay. So A x square log x y 1 double dash of x plus this is as it is, you have n is from 0 to infinity, n into n minus 1 d n x power n minus 2 minus 2 by x, n is from 1 to infinity, n d n x power n minus 1. So this is my x square y 2 double dash.

(Refer Slide Time: 11:14)

$$x^2 y''(x) = -A y(x) + 2A y'(x) + 2Ax y'(x) + 2x^2 \log x y''(x) + \sum_{n=2}^{\infty} n(n-1) d_n x^{n-2} - \frac{2}{x} \sum_{n=1}^{\infty} n d_n x^{n-1}$$

$$- \frac{2}{x} \sum_{n=1}^{\infty} n d_n x^{n-1} + \frac{6}{x} \sum_{n=0}^{\infty} d_n x^n \checkmark$$

$$2x y'(x) = 2A y(x) + 2Ax \log x y'(x) + 2x \sum_{n=1}^{\infty} n d_n x^{n-1} - \frac{4}{x} \sum_{n=0}^{\infty} d_n x^n \checkmark$$

$$x^2 y''(x) = Ax y(x) + Ax^2 \log x y'(x) + \sum_{n=1}^{\infty} n d_n x^{n-1} - \frac{2}{x} \sum_{n=0}^{\infty} d_n x^n \checkmark$$

Given eqn: $x^2 y'' + x(2+x)y' - 2y = 0$

$$-A y(x) + 2Ax y'(x) + Ax^2 \log x y''(x) + \sum_{n=2}^{\infty} n(n-1) d_n x^{n-2} - \frac{2}{x} \sum_{n=1}^{\infty} n d_n x^{n-1}$$

Now you add these two. So this $2x y''$ that also if you add so basically I am adding these two. So $2x y''$ plus x^2 if you add it so you can see that $2Ax \log x$ if there are some common terms you can add it, okay. So if it is not, maybe you have to rewrite everything as it is. So let me write. So you have $2Ay + 2Ax \log x y'$ dash x, y' is the first series solution which we already obtained, okay, $2 \times x^{-1}$, n is 1 to infinity, $n d_n x^{n-1}$ minus $2 \times x^{-2}$, n is from 0 to infinity, $d_n x^n$.

That is my $2Ax y''$ plus $x^2 y''$ that also you add. $Ax y'$, $Ax^2 \log x y'$ dash x plus $\sum_{n=1}^{\infty} n d_n x^{n-1}$ minus $2 \times x^{-2}$ by x , n is from 0 to infinity, $d_n x^n$. And then minus $2y$. So what is your y'' ? y'' is the form which you chosen, $Ay + 2Ax \log x y'$ minus $2x^{-2}$ sigma, n is from 0 to infinity, $d_n x^n$. That is what is the form, okay, this one. So n is from 0 to infinity. So d_n this is equal to minus 2 times of that is 0.

(Refer Slide Time: 13:25)

given eqn: $x^2 y'' + x(2+x)y' - 2y = 0$

$$\begin{aligned}
 & -A y(x) + 2Ax y'(x) + Ax^2 \log x y''(x) + \sum_{n=2}^{\infty} n(n-1) d_n x^{n-2} - \frac{2}{x} \sum_{n=1}^{\infty} n d_n x^{n-1} \\
 & + 2A y(x) + 2Ax \log x y'(x) + 2x^{-1} \sum_{n=1}^{\infty} n d_n x^{n-1} - \frac{4}{x^2} \sum_{n=0}^{\infty} d_n x^n \\
 & + Ax y'(x) + Ax^2 \log x y''(x) + \sum_{n=1}^{\infty} n d_n x^{n-1} - \frac{2}{x} \sum_{n=0}^{\infty} d_n x^n \\
 & - 2A y(x) \log x - 2x^{-1} \sum_{n=0}^{\infty} d_n x^n = 0
 \end{aligned}$$

So this is what is the reaction. Once you substitute y_2 , y_2 dash, y_2 double dash into this into this given equation this is what you got. You can observe the coefficient of $\log x$. What is the coefficient of $\log x$? If you see the coefficient of $\log x$, $A \log x$ for example. $A \log x$ is the coefficient, you take $A \log x$ out, you see the coefficient what you have. So $x^2 y_2$ double dash of x , okay. So this term take n . Where else you have? So you have here.

So and this will give me $2x y_2$ dash of x and then here this will give me plus $x^2 y_2$ dash dash of x . $(())(14:11)$ So this is going to be minus $2 y_2$ dash of x . But now that this is 0 so this is actually the exact equation. This together if you see this together, this is the actual equation. So original equation is this is actually given equation satisfied by y_1 . So we know that this is actually equal to 0, okay. So because of that these three terms will be 0, these four terms, okay. That is what we have done now.

(Refer Slide Time: 14:46)

$$\begin{aligned}
 & -A y_1(x) + 2xA y_1'(x) + \cancel{Ax^2 y_1''(x)} + \sum_{n=L}^{\infty} n(n-1) d_n x^{n-2} - \frac{2}{x} \sum_{n=1}^{\infty} n d_n x^{n-1} \\
 & + 2A y_1(x) + \cancel{2Ax^2 y_1''(x)} + 2x^{-1} \sum_{n=1}^{\infty} n d_n x^{n-1} - \frac{4}{x^2} \sum_{n=0}^{\infty} d_n x^n \\
 & + Ax y_1(x) + \cancel{Ax^2 y_1''(x)} + \sum_{n=1}^{\infty} n d_n x^{n-1} - \frac{2}{x} \sum_{n=0}^{\infty} d_n x^n \\
 & - \cancel{2A y_1(x)} - 2x^{-L} \sum_{n=0}^{\infty} d_n x^n = 0 \\
 & A y_1 \left[\cancel{x^2 y_1''(x)} + \cancel{x(2+x) y_1'(x)} - 2 y_1(x) \right]
 \end{aligned}$$

Now what else is left? what is left here is minus A y 1, okay, minus A y 1 so you can write minus A y 1 of x, then 2 x A y 1 dash. Is there any other thing? There is nothing so you have to write it. So 2 x A y 1 dash of x and then 2 A y 1, 2 A y 1 and minus A y 1, so that is going to be plus, okay. So this is together will give me only A y 1. So that is why I have written here and you have written this part here.

(Refer Slide Time: 15:39)

$$\begin{aligned}
 & -A y_1(x) + 2xA y_1'(x) + \cancel{Ax^2 y_1''(x)} + \sum_{n=L}^{\infty} n(n-1) d_n x^{n-2} - \frac{2}{x} \sum_{n=1}^{\infty} n d_n x^{n-1} \\
 & + 2A y_1(x) + \cancel{2Ax^2 y_1''(x)} + 2x^{-1} \sum_{n=1}^{\infty} n d_n x^{n-1} - \frac{4}{x^2} \sum_{n=0}^{\infty} d_n x^n \\
 & + Ax y_1(x) + \cancel{Ax^2 y_1''(x)} + \sum_{n=1}^{\infty} n d_n x^{n-1} - \frac{2}{x} \sum_{n=0}^{\infty} d_n x^n \\
 & - \cancel{2A y_1(x)} - 2x^{-L} \sum_{n=0}^{\infty} d_n x^n = 0 \\
 & A y_1 \left[\cancel{x^2 y_1''(x)} + \cancel{x(2+x) y_1'(x)} - 2 y_1(x) \right] + A y_1(x) + 2xA y_1'(x)
 \end{aligned}$$

Now what is left is A x y 1 so that this together A x y 1 so you have A x y 1 of x, okay. In this one now you write all the remaining series, okay. So what is the remaining series? So take all this 6 terms, okay, 7 terms. So if you write this n is from 2 to infinity, n into n minus 1 d n x power n minus 2 minus 2 by x, n is from 1 to infinity, n d n x power n minus 1 plus 2 by x, n

is from 1 to infinity, $n d n x$ power n minus 1. So this is actually this is also cancelled, okay. So 2 by $x n d n x$ power n minus 1, n is from 1 to infinity so this and this will go.

(Refer Slide Time: 16:47)

Handwritten mathematical derivation on a whiteboard showing the simplification of a differential equation using power series. The derivation starts with a given equation and proceeds through several steps of differentiation and summation, eventually leading to a simplified equation where terms cancel out, resulting in zero.

$$\begin{aligned}
 & \text{Given eqn: } x^2 y'' + x(2+x)y' - 2y = 0 \\
 & -A y''(x) + 2xA y'(x) + A x^2 y''(x) + \sum_{n=2}^{\infty} n(n-1) d_n x^{n-2} - \frac{2}{x} \sum_{n=1}^{\infty} n d_n x^{n-1} \\
 & + 2A y'(x) + 2Ax \log x y'(x) + 2x^{-1} \sum_{n=1}^{\infty} n d_n x^{n-1} - \frac{4}{x^2} \sum_{n=0}^{\infty} d_n x^n \\
 & + Ax y'(x) + Ax \log x y'(x) + \sum_{n=1}^{\infty} n d_n x^{n-1} - \frac{2}{x} \sum_{n=0}^{\infty} d_n x^n \\
 & - 2A \log x - 2x^{-1} \sum_{n=0}^{\infty} d_n x^n = 0 \\
 & A \log x \left[\cancel{x^2 y''(x)} + \cancel{x(2+x)y'(x)} - 2y(x) \right] + A y''(x) + 2xA y'(x) + Ax y'(x) \\
 & \sum_{n=2}^{\infty} n(n-1) d_n x^{n-2} - \frac{2}{x} \sum_{n=1}^{\infty} n d_n x^{n-1} + \frac{2}{x} \sum_{n=1}^{\infty} n d_n x^{n-1} = 0
 \end{aligned}$$

So I do not have to write, okay. So this I have written these two gone now these two. So if you look at this you have minus 4 by x square sigma, n is from 0 to infinity, $d n x$ power n plus sigma, n is from 1 to infinity, $n d n x$ power n minus 1 minus 2 by x , n is from 0 to infinity, $n d n x$ power n . And then here 2 by x square $d n x$ power n , so minus 2 by x square minus that is going to be 6. So these two together. So this one and this one you put it together that is going to be minus 6 I have written here and these two as it is here. So that is equal to 0.

(Refer Slide Time: 17:46)

Handwritten mathematical derivation on a whiteboard, similar to the previous one, but with a different final result. The derivation follows the same steps but ends with a different simplified equation involving a sum of terms equal to zero.

$$\begin{aligned}
 & \text{Given eqn: } x^2 y'' + x(2+x)y' - 2y = 0 \\
 & -A y''(x) + 2xA y'(x) + A x^2 y''(x) + \sum_{n=2}^{\infty} n(n-1) d_n x^{n-2} - \frac{2}{x} \sum_{n=1}^{\infty} n d_n x^{n-1} \\
 & + 2A y'(x) + 2Ax \log x y'(x) + 2x^{-1} \sum_{n=1}^{\infty} n d_n x^{n-1} - \frac{4}{x^2} \sum_{n=0}^{\infty} d_n x^n \\
 & + Ax y'(x) + Ax \log x y'(x) + \sum_{n=1}^{\infty} n d_n x^{n-1} - \frac{2}{x} \sum_{n=0}^{\infty} d_n x^n \\
 & - 2A \log x - 2x^{-1} \sum_{n=0}^{\infty} d_n x^n = 0 \\
 & A \log x \left[\cancel{x^2 y''(x)} + \cancel{x(2+x)y'(x)} - 2y(x) \right] + A y''(x) + 2xA y'(x) + Ax y'(x) \\
 & \sum_{n=2}^{\infty} n(n-1) d_n x^{n-2} - \frac{6}{x^2} \sum_{n=0}^{\infty} d_n x^n + \sum_{n=1}^{\infty} n d_n x^{n-1} - \frac{2}{x} \sum_{n=0}^{\infty} d_n x^n = 0
 \end{aligned}$$

So this is what we have. So anyways this is gone so what is left is only this part. So this is the equation. Now we know what is y_1 . So y_1 is a series we know, y_1 dash. So you can rewrite and substitute your y_1 here as a series so remaining parts are all series. You substitute here and you will be able to find, once you get a series you replace y_1 as a series. You will see the once y_1 you replace with the series which you know as a first solution and you will get all the terms one, two, three, four, five, six, seven terms.

Among the seven terms in the equations you have last four terms or series. First three terms if you replace y_1 as series, y_1 is a series solutions. So you calculate y_1 dash, substitute in the first three terms you will see that seven series together equal to 0. So now that you expand and make the coefficients of each of this coefficients of x power n 0 that will determine all the unknown coefficients so which are A and d_n s, okay.

So we can see that. So what is your y_1 ? For that you need y_1 . So what is the y_1 you got? so this is what is your y_1 . So y_1 is x minus x power x square by 4. So y_1 is x minus x square by 4, x cube by 4 5, like that, okay. So we will see exactly. So we will calculate that y_1 . So what is your y_1 ? y_1 is $y_1 x$ since $y_1 x$ is given as x minus x square by 4 plus x cube by 4 5 minus x power 4 by 4 5 6 and then plus x power 5 by 4 5 6 7 and so on, it will go on like this. This is your series solution which you got from the first solution, okay.

(Refer Slide Time: 19:41)

The image shows a digital whiteboard with handwritten mathematical work. At the top, there are some scribbles and the equation $\sum_{n=1}^{\infty} n^n x^n - \sum_{n=2}^{\infty} d_n x^n = 0$. Below that, the equation $-2A \frac{d}{dx} y_1 - 2x^{-1} \sum_{n=2}^{\infty} d_n x^n = 0$ is written. The next line shows the substitution of $y_1 = x - \frac{x^2}{4} + \frac{x^3}{4 \cdot 5} - \frac{x^4}{4 \cdot 5 \cdot 6} + \frac{x^5}{4 \cdot 5 \cdot 6 \cdot 7} - \dots$ into the equation, resulting in $A \log x \left[x^2 y_1''(x) + x(x+1) y_1'(x) - 2y_1(x) \right] + A y_1'(x) + 2x A y_1'(x) + A x y_1''(x)$. This is followed by the coefficient equation $\sum_{n=2}^{\infty} n(n-1) d_n x^{n-2} - \frac{6}{x} \sum_{n=2}^{\infty} d_n x^n + \sum_{n=1}^{\infty} n d_n x^{n-1} - \frac{2}{x} \sum_{n=2}^{\infty} d_n x^n = 0$. At the bottom, the series solution is written as $\text{Since } y_1(x) = x - \frac{x^2}{4} + \frac{x^3}{4 \cdot 5} - \frac{x^4}{4 \cdot 5 \cdot 6} + \frac{x^5}{4 \cdot 5 \cdot 6 \cdot 7} - \dots$.

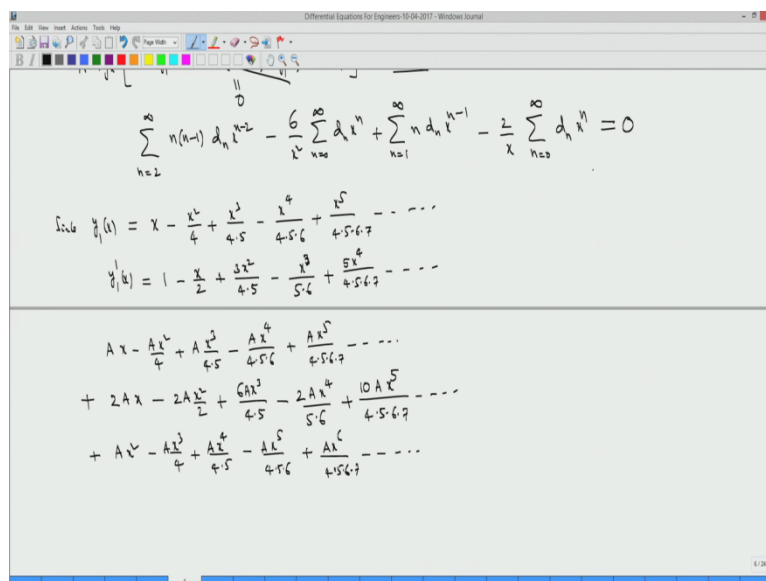

So this is this one. So once you get this y_1 so you need to substitute here. So for that you need y_1 dash so you calculate y_1 dash of x . So that will give me 1 minus x by 2 minus $3x$ square by $4 \cdot 5$ minus $4x$ cube by $5 \cdot 6$, 4 goes and then plus $5x$ power 4 , $4 \cdot 5 \cdot 6 \cdot 7$ and so on,

okay. these two if you try to substitute that into equation. So if you substitute A times A x minus A x square by 4, A x cube by 4 5 minus A x power by 4 5 6 plus A x power 5 by 4 5 6 7 and so on, okay. So this is my first term A into y 1 x.

This is your A into y 1 x that I substituted now. Now plus 2 A x into y dash. So 2 A x into y 1 dash is 2 A x. So just multiplying 2 A x to your y 1 dash. 2 A x minus 2 A x square by 2 minus 6 A x cube by 4 5, okay. 2 A x is going to be x cube so minus so this is plus, right, this is plus. It should differentiate so one plus minus plus minus.

So you have this as plus and now minus 2 A x power 4 by 5 6 plus 2 is 10, so 10 A x power 5 2 A x divided by 4 5 6 7 and so on. So that is your second term. Third term is A x y 1 dash x. So you multiplying A x 2 y 1. So that will give me A x square minus A x cube by 4 plus A x power 4 by 4 5, A x power 5 by 4 5 6 plus A x power 6 by 4 5 6 7 and so on, okay. So these are the three terms. Now I wrote it as series.

(Refer Slide Time: 22:48)

$$\sum_{n=2}^{\infty} n(n-1) d_n x^{n-2} - 6 \sum_{n=0}^{\infty} d_n x^n + \sum_{n=1}^{\infty} n d_n x^{n-1} - x \sum_{n=0}^{\infty} d_n x^n = 0$$

Solve $y_1(x) = x - \frac{x^2}{4} + \frac{x^3}{4.5} - \frac{x^4}{4.5.6} + \frac{x^5}{4.5.6.7} - \dots$

$y_2(x) = 1 - \frac{x}{2} + \frac{dx^2}{4.5} - \frac{x^3}{5.6} + \frac{5x^4}{4.5.6.7} - \dots$

$$Ax - \frac{Ax^2}{4} + \frac{Ax^3}{4.5} - \frac{Ax^4}{4.5.6} + \frac{Ax^5}{4.5.6.7} - \dots$$

$$+ 2Ax - 2A\frac{x^2}{2} + \frac{6Ax^3}{4.5} - \frac{2Ax^4}{5.6} + \frac{10Ax^5}{4.5.6.7} - \dots$$

$$+ Ax^2 - \frac{Ax^3}{4} + \frac{Ax^4}{4.5} - \frac{Ax^5}{4.5.6} + \frac{Ax^6}{4.5.6.7} - \dots$$

This also I can expand. So even this series terms also you can now expand and write it as a full series. So if you write that so you will get this series if you write n equal to 2 so you will get 2 times, n equal to 2 if you put 2 d 2 that is 0 plus n equal to 3, 6 d 3 x plus n equal to 4, 12 d 4 x square. So I will write four terms, okay. 5 n equal to 5 that will give me 20 d 5 x cube and so on.

If required you can add it later here, okay. So that is my this series. So next one is minus 6 by x square, n equal so d is d 0, n equal to 0, okay, and then minus 6 by x square, n equal to 1 will give me d 1 that is going to be x. So that x this x goes so 6 by x. Again minus 6 by x

square. So we have d^2 . This x^2 and $d^2 x^2$ will go so will give me $-6 d^2$. And then $-6 x d^3 - 6 x^2 d^4$ and so on like that you get the second one.

Third term you can see that n equal to 1 so d^1 plus n equal to 2, $2 d^2 x$ plus $3 d^3 x^2$ plus $4 d^4 x^3$ and so on. Finally the last term -2 by $x d^0 - 2$ by $x d^1 x$. So that x goes, okay, so you have $-2 d^1$. So -2 by $x d^2 x^2$.

So that is going to be $x - 2 x^2$ so $-2 d^3 x^2 - 2 d^4 x^3$ and so on, okay. All will be minus. And n equal to 4 you have -2 by $x d^4 x^4$, so $x x$ goes x^3 and so on. So this is what I replaced all the series I expanded them. This is actually equal to 0.

(Refer Slide Time: 26:00)

So since y_1 and y_2 are solutions, y_1 is a solution and you already know that y_2 is also going to be solution. These are absolutely and uniformly continuous in the domain where it is defined, okay. So this I have given without proof is our uniformly convergent. So that you can add term by term and so you can put it together, okay. So that is why I am able to add all these series together. Now simply get the coefficient of lowest terms, okay.

So what is the lowest coefficient here? So first series I think only starts from x , second series also starts from x , third is also like that. The fourth one is also like that. So fifth one is -6 by x^2 . So you have x power minus 2 coefficient, pickup the coefficient, okay. So coefficient of x make it 0. What is the reason? So I have coefficient of x power so $C - 2x - 2$, $C - 2$ or rather $C - 2$ I put it here, okay, $x - 1$ and so on.

So $C_0 x$ plus $C_1 x$ plus $C_2 x^2$ square, like that I am going to put equal to 0. So these are C_1 , C_0 , C_1 , C_2 , these are all the coefficients of x power minus 2 x power minus 1 so on.

(Refer Slide Time: 27:30)

$$y(x) = 1 - \frac{x}{2} + \frac{x^2}{4 \cdot 5} - \frac{x^3}{5 \cdot 6} + \frac{x^4}{4 \cdot 5 \cdot 6} - \dots$$

$$y'(x) = Ax - \frac{Ax^2}{4} + \frac{Ax^3}{4 \cdot 5} - \frac{Ax^4}{4 \cdot 5 \cdot 6} + \frac{Ax^5}{4 \cdot 5 \cdot 6 \cdot 7} - \dots$$

$$+ 2Ax - 2Ax^2 + \frac{6Ax^3}{4 \cdot 5} - \frac{2Ax^4}{5 \cdot 6} + \frac{10Ax^5}{4 \cdot 5 \cdot 6 \cdot 7} - \dots$$

$$+ Ax^2 - \frac{Ax^3}{4} + \frac{Ax^4}{4 \cdot 5} - \frac{Ax^5}{4 \cdot 5 \cdot 6} + \frac{Ax^6}{4 \cdot 5 \cdot 6 \cdot 7} - \dots$$

$$+ 2d_2 + 6d_3x + 12d_4x^2 + 20d_5x^3 + \dots$$

$$- \frac{6}{x}d_0 - \frac{6}{x}d_1 - 6d_2 - 6 \cdot 2d_3 - 6 \cdot 3d_4 - \dots$$

$$+ \frac{1}{x}d_1 + 2d_2x + 3d_3x^2 + 4d_4x^3 + \dots$$

$$- \frac{2}{x}d_0 - 2d_1 - 2d_2x - 2d_3x^2 - 2d_4x^3 - \dots = 0$$

Coeff $x^{-2} = 0$:

So like this if you have a series equal to 0, each of these coefficients have to be 0. That is why I am making it equal to 0. Coefficient of x^2 that is here $C_{\text{minus } 2}$ which is 0 which I am calling simply whatever, okay. I am saying what this $C_{\text{minus } 2}$ is. That I have only minus 6 d_0 , okay, is equal to 0. So there is no such thing that is the coefficient of x power minus 2 that has to be 0. So it immediately gives me d_0 is 0, okay.

And similarly coefficient of x power minus 1 make it 0. So this will give me what is that you have so 1 by x minus 6 d_1 . What is other one? So minus 2 d_0 equal to 0. This will give me I already know that d_0 is 0 that will give me d_1 is also 0, okay. And then make the coefficient of 0 is 0. Coefficient of x power 0 is 0. That will what will give? So what you get constant term.

There is the constant term in each of the series. In all these seven series terms. So you have 2 d_2 minus 6 d_2 , okay. So I have here 6 d_2 , 2 d_2 , 6 d_2 , okay. So I may not write anything here so plus d_1 . So d_1 which is already 0 equal to 0. So d_1 is already 0 so d_2 is again minus 4 d_2 is 0. That will also going to make it d_2 0.

(Refer Slide Time: 29:15)

The image shows a whiteboard with handwritten mathematical work. The top part shows the expansion of a differential equation with terms involving x^4 , x^3 , x^2 , x , and constant terms. The terms are grouped and simplified. The bottom part shows three equations derived from setting the coefficients of x^2 , x^1 , and x^0 to zero, leading to $d_0 = 0$, $d_1 = 0$, and $d_2 = 0$.

$$\begin{aligned}
 &+ 2Ax - 2A\frac{x^2}{2} + \frac{6Ax^3}{4 \cdot 5} - \frac{2Ax^4}{5 \cdot 6} + \frac{10Ax^5}{4 \cdot 5 \cdot 6 \cdot 7} \dots \\
 &+ Ax^2 - \frac{Ax^3}{4} + \frac{Ax^4}{4 \cdot 5} - \frac{Ax^5}{4 \cdot 5 \cdot 6} + \frac{Ax^6}{4 \cdot 5 \cdot 6 \cdot 7} \dots \\
 &+ 2d_2 + 6d_3x + 12d_4x^2 + 20d_5x^3 + \dots \\
 &- \frac{6}{x^2}d_0 - \frac{6}{x}d_1 - 6d_2 - 6 \cdot 2d_3 - 6 \cdot x d_4 \dots \\
 &+ d_1 + 2d_2x + 3d_3x^2 + 4d_4x^3 + \dots \\
 &- \frac{2}{x}d_0 - 2d_1 - 2d_2x - 2d_3x^2 - 2d_4x^3 \dots = 0
 \end{aligned}$$

Coefficients:

$$\begin{aligned}
 \frac{x^2}{x^2} = 0 &: -6d_0 = 0 \Rightarrow d_0 = 0 \\
 \frac{x^1}{x^1} = 0 &: -6d_1 - 2d_0 = 0 \Rightarrow d_1 = 0 \\
 \frac{x^0}{x^0} = 0 &: 2d_2 - 6d_1 + d_1 = 0 \Rightarrow d_2 = 0
 \end{aligned}$$

So now look at the coefficient of x^1 equal to 0. This will give me, what is the coefficient of 1 that is A , A plus $2A$ so that is going to be $3A$. $3A$ and then you have $6d_3$ minus $6d_3$. So it is going to be 0. So that is why I do not have anything and here plus $2d_2$ that is also 0. So that will give me A equal to 0. So we are seeing all these 0 solution something is wrong. So y_2 is satisfying this so when we substitute this y_2 double dash and y_2 dash and y_2 into this equation what we had missed is these two terms.

So when you have this x^2 y_2 double dash I added only this part so this remaining you can add here now. So you have minus 2 by x , n is from 1 to infinity, $n d_n x^{n-1}$ plus 6 by x^2 , n is from 0 to infinity, $d_n x^n$. So this is my x^2 y_2 double dash and then $2x$ y_2 dash is this four terms and then x^2 y_2 dash is this four terms. And then minus 2 y_2 is these two terms is 0.

(Refer Slide Time: 30:35)

$$-\frac{2}{x} \sum_{n=1}^{\infty} n d_n x^{n-1} + \frac{6}{x^2} \sum_{n=0}^{\infty} d_n x^n \checkmark$$

$$\checkmark 2x y_1'(x) = 2A y_1(x) + 2Ax \log x y_1'(x) + 2x \sum_{n=1}^{\infty} n d_n x^{n-1} - \frac{4}{x^2} \sum_{n=0}^{\infty} d_n x^n \checkmark$$

$$\checkmark x^2 y_2''(x) = Ax y_2(x) + Ax \log x y_2'(x) + \sum_{n=1}^{\infty} n d_n x^{n-1} - \frac{2}{x} \sum_{n=0}^{\infty} d_n x^n \checkmark$$

given eqn: $x^2 y'' + x(2+x)y' - 2y = 0 \checkmark$

$$-A y_1(x) + 2xA y_1'(x) + \cancel{Ax^2 \log x y_1''(x)} + \sum_{n=2}^{\infty} n(n-1) d_n x^{n-2} - \frac{2}{x} \sum_{n=1}^{\infty} n d_n x^{n-1} - \frac{2}{x} \sum_{n=1}^{\infty} n d_n x^{n-1} + \frac{6}{x^2} \sum_{n=0}^{\infty} d_n x^n$$

$$+ 2A y_1(x) + 2Ax \log x y_1'(x) + 2x \sum_{n=1}^{\infty} n d_n x^{n-1} - \frac{4}{x^2} \sum_{n=0}^{\infty} d_n x^n$$

$$+ Ax y_2(x) + Ax \log x y_2'(x) + \sum_{n=1}^{\infty} n d_n x^{n-1} - \frac{2}{x} \sum_{n=0}^{\infty} d_n x^n$$

$$- 2A \log x - 2x \sum_{n=0}^{\infty} d_n x^n = 0$$

So as usual so you can remove this since y_1 is satisfying these four terms whatever I cancelled is actually giving me because satisfying the this is the say first solution satisfies the given equation. So that will make it 0. So what you have is this and I have two more. So these two terms are required. So (ex) these are extra. So it is not just this. So I have to add minus 2 by x, n is from 1 to infinity, $n d_n x^{n-1}$ plus 6 by x square, n is from 0 to infinity, $d_n x^n$ which is equal to 0. So now this is what is equal to 0.

(Refer Slide Time: 31:19)

$$A \log x [x^2 y_1''(x) + x(2+x)y_1'(x) - 2y_1(x)] + A y_1(x) + 2xA y_1'(x) + Ax y_2(x)$$

$$\sum_{n=2}^{\infty} n(n-1) d_n x^{n-2} - \frac{6}{x^2} \sum_{n=0}^{\infty} d_n x^n + \sum_{n=1}^{\infty} n d_n x^{n-1} - \frac{2}{x} \sum_{n=0}^{\infty} d_n x^n - \frac{2}{x} \sum_{n=1}^{\infty} n d_n x^{n-1} + \frac{6}{x^2} \sum_{n=0}^{\infty} d_n x^n = 0$$

$$\text{So } y_1(x) = x - \frac{x^2}{4} + \frac{x^3}{4 \cdot 5} - \frac{x^4}{4 \cdot 5 \cdot 6} + \frac{x^5}{4 \cdot 5 \cdot 6 \cdot 7} - \dots$$

So when you are adding this equal to 0 so let me add these two terms which I missed earlier. So this is one so the first term so what you have is so the last time which we missed this if you write it also you have minus 2 by x. So let me see if they are common to anywhere. So

we have they are not common. So we have 6 d n square d n. So this will go, these two terms will go.

So I do not have to write the second term, okay. So you have one, two, three, four, fifth, fifth series you do not have to write. So one, two, three, four, five so this part is actually not required because they get cancelled with the last one, okay.

(Refer Slide Time: 32:21)

The image shows a whiteboard with handwritten mathematical work. At the top, there are several summation formulas involving $n(n-1)d_n x^{n-2}$, $\sum \frac{d_n x^n}{x}$, and $\sum \frac{d_n x^n}{x}$. Below these, the series for $y_1(x)$ and $y_2(x)$ are written out as $x - \frac{x^2}{4} + \frac{x^3}{4 \cdot 5} - \frac{x^4}{4 \cdot 5 \cdot 6} + \frac{x^5}{4 \cdot 5 \cdot 6 \cdot 7} - \dots$ and $1 - \frac{x}{2} + \frac{2x^2}{4 \cdot 5} - \frac{x^3}{5 \cdot 6} + \frac{2x^4}{4 \cdot 5 \cdot 6 \cdot 7} - \dots$. The main part of the whiteboard shows a series of terms being added together, such as $Ax - \frac{Ax^2}{4} + \frac{Ax^3}{4 \cdot 5} - \frac{Ax^4}{4 \cdot 5 \cdot 6} + \frac{Ax^5}{4 \cdot 5 \cdot 6 \cdot 7} - \dots$, followed by $+ 2Ax - 2A\frac{x^2}{2} + \frac{6Ax^3}{4 \cdot 5} - \frac{2Ax^4}{5 \cdot 6} + \frac{10Ax^5}{4 \cdot 5 \cdot 6 \cdot 7} - \dots$, and then $+ Ax^2 - \frac{Ax^3}{4} + \frac{Ax^4}{4 \cdot 5} - \frac{Ax^5}{4 \cdot 5 \cdot 6} + \frac{Ax^6}{4 \cdot 5 \cdot 6 \cdot 7} - \dots$. The final result is shown as $\frac{c_2}{x^2} + \frac{c_1}{x} + c_0 + c_1x + c_2x^2 + \dots = 0$.

So this series is getting cancelled with the last one so only you have to add this term so which I missed, minus 2 by x n d n. So minus 2 by x, okay, so you have minus 2 by x, n equal to 1 that will give me d 1. So 2 by x d 1 minus 2 by x and then you have n equal to 2, you get 2 d 2 x minus 2 by x 3 d 3 x square minus 2 by x 4 d 4 x cube and so on. So that is what is equal to 0. So I have a now one, two, three, four, five, six, seven, seven series which are 0. So you have three terms here four, five, six, seven, okay. These two series gets cancelled.

(Refer Slide Time: 33:25)

The image shows a handwritten derivation in a software window titled "Differential Equations for Engineers-10-04-2017 - Windows Journal". The derivation starts with the equation:

$$-2Ax - 2x \sum_{n=2}^{\infty} d_n x^n = 0$$

Then it shows the expansion of $A \log x$ as a power series:

$$A \log x = A \left[x^{-1} + \frac{1}{2} x^{-2} + \frac{1}{3} x^{-3} + \dots \right]$$

The next step involves substituting this into the differential equation and simplifying the resulting series. The final result is a series of terms that must equal zero:

$$Ax - \frac{Ax^2}{4} + \frac{Ax^3}{4.5} - \frac{Ax^4}{4.5.6} + \frac{Ax^5}{4.5.6.7} - \dots$$

$$+ 2Ax - 2A \frac{x^2}{2} + \frac{6Ax^3}{4.5} - 2A \frac{x^4}{5.6} + \frac{10Ax^5}{4.5.6.7} - \dots$$

$$+ Ax^2 - \frac{Ax^3}{4} + \frac{Ax^4}{4.5} - \frac{Ax^5}{4.5.6} + \frac{Ax^6}{4.5.6.7} - \dots$$

The final equation is:

$$c_2 x^{-2} + c_1 x^{-1} + c_0 + c_1 x + c_2 x^2 + \dots = 0$$

So now make the coefficients of x power minus 2 0 so what you will get coefficient of x power minus 2 is 0 will give me d 0 is 0, okay. Let me see what you have x power plus what you will get, this gets cancelled so you have x power A y 1. So y 1 2 x, x power this so you have there is no x power minus 2 term, right? So everything is powers of maximum x power minus 1. So this here x x goes, okay. Minus 2 by x so this is going to be 4 d 2.

(Refer Slide Time: 34:25)

The image shows a handwritten derivation in a software window titled "Differential Equations for Engineers-10-04-2017 - Windows Journal". The derivation starts with the equation:

$$Ax - \frac{Ax^2}{4} + \frac{Ax^3}{4.5} - \frac{Ax^4}{4.5.6} + \frac{Ax^5}{4.5.6.7} - \dots$$

Then it shows the expansion of $2Ax$ as a power series:

$$2Ax = 2Ax - 2A \frac{x^2}{2} + \frac{6Ax^3}{4.5} - 2A \frac{x^4}{5.6} + \frac{10Ax^5}{4.5.6.7} - \dots$$

The next step involves substituting this into the differential equation and simplifying the resulting series. The final result is a series of terms that must equal zero:

$$Ax^2 - \frac{Ax^3}{4} + \frac{Ax^4}{4.5} - \frac{Ax^5}{4.5.6} + \frac{Ax^6}{4.5.6.7} - \dots$$

$$+ 2d_2 + 6d_3 x + 12d_4 x^2 + 20d_5 x^3 + \dots$$

$$+ d_1 + 2d_2 x + 3d_3 x^2 + 4d_4 x^3 + \dots$$

$$- \frac{2}{x} d_0 - 2d_1 - 2d_2 x - 2d_3 x^2 - 2d_4 x^3 - \dots$$

$$- \frac{2}{x} d_1 - 4d_2 - \frac{2}{x} 3d_3 x^2 - \frac{2}{x} 4d_4 x^3 - \dots = 0$$

The final equation is:

$$c_2 x^{-2} + c_1 x^{-1} + c_0 + c_1 x + c_2 x^2 + \dots = 0$$

Similarly here if you remove this x this is going to be x. If you remove this, this is going to be x square and so on. So you have 1 y x terms. So you have maximum lowest term is x power C minus 1. So this term is not there. So this is how the series is going to be. So all these seven series if you add up it is going to be starting from x power minus 1 that is the first time and

then so on x power 0, next term and so on. So you have x power minus 1 coefficient 0 then what you get is, so what is the coefficient of this?

You get minus d 0 minus d 1 which has to be 0. So that will give me d 0 equal to minus d 1, okay. So d 0 equal to minus d 1 and then coefficient of x is 0. So this will give me 2 d 2. So constant that is 2 d 2 plus d 1 and then minus 2 d 1 minus 4 d 2 which is equal to 0. So this will give me if you add it, it is going to be minus 2 d 2 minus d 1 which is equal to 0 so you can write d 2 as minus 1 by 2 d 1, okay.

(Refer Slide Time: 36:04)

The image shows a digital whiteboard with the following handwritten content:

$$\begin{aligned}
 & + A x^{-1} - \frac{A x^{-1}}{4} + \frac{A x^{-1}}{4 \cdot 5} - \frac{A x^{-1}}{4 \cdot 5 \cdot 6} + \frac{A x^{-1}}{4 \cdot 5 \cdot 6 \cdot 7} - \dots \\
 & + 2 d_2 + 6 d_3 x + 12 d_4 x^2 + 20 d_5 x^3 + \dots \\
 & + d_1 + 2 d_2 x + 3 d_3 x^2 + 4 d_4 x^3 + \dots \\
 & - \frac{2}{x} d_0 - 2 d_1 - 2 d_2 x - 2 d_3 x^2 - 2 d_4 x^3 - \dots \\
 & - \frac{2}{x} d_1 - 4 d_2 - 2 \cdot 3 d_3 x - 2 \cdot 4 d_4 x^2 - \dots = 0
 \end{aligned}$$

Below the expansion, the coefficients are determined:

$$\begin{aligned}
 \text{Coeff } x^{-1} = 0 &: -d_0 - d_1 = 0 \Rightarrow d_0 = -d_1 \\
 \text{Coeff } x = 0 &: 2 d_2 + d_1 - 2 d_1 - 4 d_2 = 0 \Rightarrow -2 d_2 - d_1 = 0 \Rightarrow d_2 = -\frac{1}{2} d_1
 \end{aligned}$$

And now make the coefficient of x power 0 here so coefficient of x power 1 that is coefficient of x is 0. That is going to be, what is the coefficient of x? A plus 2 A, so first two will give me A plus 2 is 3 A, okay. So these are the two terms and then here you get 6 d 3, 2 d 2 and then minus 2 d 2 and then here again minus 6 d 3 equal to 0. So that will give me 6 d 3 6 d 3 goes, 2 d 2 2 d 2 goes, 3 A equal to 0 that will give me A equal to 0.

So immediately once A is 0 the coefficient of log x for your second solution A is 0. So you will not have log term, okay. So only x power minus 2, d 0 onwards it will be there, okay. So d 0 is arbitrary, okay, so d 0 is 0. Not able to get it, right? So d 0 is given in terms of d 2 so that you can put it like d 1 equal to so this is actually like d 1 is minus d 0.

So that will give me what is d 1? D 1 is minus d 0 means this is you can write in terms of, so it is going to be half d 2, okay. So d 2 is minus half d 1, d 1 is minus d 0. So I will make it this one.

(Refer Slide Time: 37:57)

$$+ d_1 + 2d_2x + 3d_3x^2 + 4d_4x^3 + \dots$$

$$- \frac{2}{x} d_0 - 2d_1 - 2d_2x - 2d_3x^2 - 2d_4x^3 - \dots$$

$$- \frac{2}{x} d_1 - 4d_2 - 2 \cdot 3d_3x - 2 \cdot 4d_4x^2 - \dots = 0$$

coeff $x^{-1} = 0$: $-d_0 - d_1 = 0 \Rightarrow d_0 = -d_1 \Rightarrow d_1 = -d_0$ ✓
 coeff $x^0 = 0$: $2d_2 + d_1 - 2d_1 - 4d_2 = 0 \Rightarrow -2d_1 - d_1 = 0 \Rightarrow d_2 = -\frac{1}{2}d_1 = \frac{1}{2}d_0$ ✓
 coeff $x^1 = 0$: $3A + 6d_3 + 2d_2 - 2d_2 - 6d_3 = 0 \Rightarrow 3A = 0 \Rightarrow A = 0$ ✓

So you could get d_1 d_2 in terms of d_0 , d_0 is arbitrary. So like that you can go on. I can calculate one more and make it equal to 0. So coefficient of x square if you make it equal to 0 if you do it meticulously (don't) it should not go wrong. You will get everything properly so you get minus A by 4. A is anyway found coefficient of, so I do not have to whenever A is there now I found A is 0 I can simply remove this and I need not construct because A is 0, okay. So A is 0 I need not worry now anymore here, okay.

(Refer Slide Time: 38:30)

~~$$Ax - \frac{Ax^2}{4} + \frac{Ax^3}{45} - \frac{Ax^4}{456} + \frac{Ax^5}{4567} - \dots$$

$$+ 2Ax - 2A\frac{x^2}{2} + \frac{6Ax^3}{45} - \frac{2Ax^4}{56} + \frac{10Ax^5}{4567} - \dots$$

$$+ Ax^2 - \frac{Ax^3}{4} + \frac{Ax^4}{45} - \frac{Ax^5}{456} + \frac{Ax^6}{4567} - \dots$$~~

$$+ 2d_2 + 6d_3x + 12d_4x^2 + 20d_5x^3 + \dots$$

$$+ d_1 + 2d_2x + 3d_3x^2 + 4d_4x^3 + \dots$$

$$- \frac{2}{x} d_0 - 2d_1 - 2d_2x - 2d_3x^2 - 2d_4x^3 - \dots$$

$$- \frac{2}{x} d_1 - 4d_2 - 2 \cdot 3d_3x - 2 \cdot 4d_4x^2 - \dots = 0$$

coeff $x^{-1} = 0$: $-d_0 - d_1 = 0 \Rightarrow d_0 = -d_1 \Rightarrow d_1 = -d_0$ ✓
 coeff $x^0 = 0$: $2d_2 + d_1 - 2d_1 - 4d_2 = 0 \Rightarrow -2d_1 - d_1 = 0 \Rightarrow d_2 = -\frac{1}{2}d_1 = \frac{1}{2}d_0$ ✓
 coeff $x^1 = 0$: $3A + 6d_3 + 2d_2 - 2d_2 - 6d_3 = 0 \Rightarrow 3A = 0 \Rightarrow A = 0$ ✓

So I have to take coefficient of x square. Coefficient of x square is $12d_4$ and then plus $3d_3$ minus $2d_3$ from here on here minus $8d_4$ equal to 0. So that will give me 12 minus 8 , $4d_4$ and plus d_3 equal to 0. So that will give me d_4 equal to minus d_3 by 4, okay. So what is d

3? d_3 is arbitrary now, okay, d_3 and d_0 both are arbitrary. That is what you are seeing, okay. I could not get d_3 . So let me calculate one more term so coefficient of x^3 equal to 0 if you make it what happens?

So sometimes you will get all the coefficients except one or if you look at this form of the second solution, okay, where is your second solution? So this is in this form. Either I may get all these constants A and d_n s so that you know exactly what is your y^2 or rather A and d_n s, you will be able to find all these constants in terms of one constant, okay. So that means you calculate all of them except one.

But you write everything else in terms of one constant that means so that the constant comes out and some power series, okay. That way you will get it so once you take whatever the arbitrary constant you take it as one. So once you take that as arbitrary constant one that will be a solution. That way you can get or if you sometimes you may end up getting some solutions in terms of one arbitrary constant, some solution in terms of some other arbitrary constant.

For example in this case when A is 0 that is what I am getting, okay. So if you see this A got 0 and d_1 d_2 are given in terms of d_0 , d_4 in terms of d_3 because d_3 I could not find that means d_3 is arbitrary. Now if you make it coefficient of x^3 is 0 from these three. So if you look at this $20d_5$, okay, so then what you have?

So it is going to be x^3 is $4d_4$ and then 4 is minus $2d_4$ and what I get here so this is going to be coefficient of, so what you get is one more term is actually here minus 2 by $x^5 d_5$ x^3 , okay, $5d_5 x^4$. So that is going to be x^3 with removing this.

(Refer Slide Time: 41:36)

$$+ 2d_2 + 6d_3x + 12d_4x^2 + 20d_5x + \dots$$

$$+ d_1 + 2d_2x + 3d_3x^2 + 4d_4x^3 + \dots$$

$$- \frac{2}{x}d_0 - 2d_1 - 2d_2x - 2d_3x^2 - 2d_4x^3 - \dots$$

$$- \frac{2}{x}d_1 - 4d_2 - 2 \cdot 3d_3x - 2 \cdot 4d_4x^2 - 2 \cdot 5d_5x^3 = 0$$

Coeff $x^{-1} = 0$: $-d_0 - d_1 = 0 \Rightarrow d_0 = -d_1 \Rightarrow d_1 = -d_0$ ✓
 Coeff $x^0 = 0$: $2d_2 + d_1 - 2d_1 - 4d_2 = 0 \Rightarrow -2d_1 - d_1 = 0 \Rightarrow d_2 = -\frac{1}{2}d_1 = \frac{1}{2}d_0$ ✓
 Coeff $x^1 = 0$: $3A + 6d_3 + 2d_2 - 2d_2 - 6d_3 = 0 \Rightarrow 3A = 0 \Rightarrow A = 0$ ✓
 Coeff $x^2 = 0$: $12d_4 + 3d_3 - 2d_3 - 8d_4 = 0 \Rightarrow 4d_4 + d_3 = 0 \Rightarrow d_4 = -\frac{d_3}{4}$
 Coeff $x^3 = 0$: $20d_5 + 4d_4 - 2d_4$

So you have 2 5 and so on. So you have minus 10 d 5, okay, that is what you get, equal to 0. So this will give me 10 d 5 plus 2 d 4 equal to 0. So this will give me d 5 as 1 by 5 minus 1 by 5 d 4. And d 4 is given in terms of minus d 3. So it is going to be plus d 3. So you have d 3 by 4 5, okay, and so on you will get it. So like this you are getting. So what you are getting finally is y 2 of x which is given as A into log x. A y 1 into log x, A is 0, A I found to be 0.

So that is going to be that term will not be there and you have x power minus 2. So d 0 is I did not find. So d 0 I did not find. So d 0 plus d 1, d 1 is minus d 0 x, okay. What is d 2? Plus half d 0 that is my d 2 x square, okay. These are all given in terms of d 0, plus remaining are d 3, I could not find d 3, d 3 x cube and d 4 is minus d 3 by 4 x power 4. What is d 5? D 5 is d 3 by 4 5 x power 5 and so on. So you can expect next one will be minus d 3 by 4 5 6 x power 6, okay, like that you can expect.

(Refer Slide Time: 43:29)

$$-\frac{2}{x} d_0 - 2 d_1 - 2 d_2 x - 2 d_3 x^2 - 2 d_4 x^3 - 2 d_5 x^4 - \dots = 0$$

$$-\frac{2}{x} d_1 - 4 d_2 - 2 d_3 x - 2 d_4 x^2 - 2 d_5 x^3 - \dots = 0$$

Coeff $x^{-1} = 0$: $-d_0 - d_1 = 0 \Rightarrow d_1 = -d_0 \Rightarrow d_1 = -d_0$ ✓
 Coeff $x^0 = 0$: $2d_2 + d_1 - 2d_1 - 4d_2 = 0 \Rightarrow -2d_1 - d_1 = 0 \Rightarrow d_2 = -\frac{1}{2}d_1 = \frac{1}{2}d_0$ ✓
 Coeff $x^1 = 0$: $3A + 6d_3 + 2d_2 - 2d_2 - 6d_3 = 0 \Rightarrow 3A = 0 \Rightarrow A = 0$ ✓
 Coeff $x^2 = 0$: $12d_4 + 3d_3 - 2d_3 - 8d_4 = 0 \Rightarrow 4d_4 + d_3 = 0 \Rightarrow d_4 = -\frac{d_3}{4}$
 Coeff $x^3 = 0$: $20d_5 + 4d_4 - 2d_4 - 10d_5 = 0 \Rightarrow 10d_5 + 2d_4 = 0 \Rightarrow d_5 = -\frac{1}{5}d_4 = \frac{d_3}{4 \cdot 5}$

$$y_2(x) = x^{-2} \left(d_0 - d_1 x + \frac{1}{2} d_2 x^2 \right) + x^{-2} \left(d_3 x^3 - \frac{d_3}{4} x^4 + \frac{d_3}{4 \cdot 5} x^5 - \frac{d_3}{4 \cdot 5 \cdot 6} x^6 + \dots \right)$$

So what you got finally this is equal to d_0 times, so 1 by x square, take this x power minus 2 inside you get minus 1 by x plus 1 by 2. So this is your solution. So this is your d_0 into this plus now if you do this, this is going to be d_3 comes out as constant. This is going to be x minus x square. If you take this x square by 4 and then you have plus x cube by 4 5, okay, and then minus x power 4 by 4 5 6 and so on. So what is this? This you already know this is exactly your y_1 of x , okay.

So sometimes you may get your second solution in terms of something as your y_2 plus y_1 , okay, like here. So I do not need this y_1 because I already got my y_1 , okay. So this itself is second linearly independent solutions first of all. If you do not want this form and you already have y_1 you take whatever, if y_1 is part of solution into your second solution y_2 you can remove it, you can split it and remove it. So this is my y_1 .

I do not want that so you take d_3 as 0 and d_0 is arbitrary that you take it as 1 so that you get your second solution y_2 as 1 by x square minus 1 by x plus half. So this is your second linearly independent solution. This is also linearly independent solutions like y_1 x , so I got some y_2 of x , some function here so this is your say your y_2 x plus some arbitrary constant d_3 times y_1 of x . This is also solution. These are two linearly independent solutions because y_1 and y_2 are two linearly independent solutions, okay.

You see that this part and this part are two linearly independent solutions. This already know so you can remove it. So this is your secondly linearly independent solution or here itself you

can say this whole thing together you can consider d_0 equal to 1 and d_3 as also 1. You can also say that this is a series solution which is also linearly independent solution, okay.

(Refer Slide Time: 45:47)

$$20d_3 + 4d_4 - 2d_4 - 10d_3 = 0 \Rightarrow 10d_3 + 2d_4 = 0 \Rightarrow d_3 = -\frac{1}{5}d_4 = \frac{d_5}{4.5}$$

$$y_2(x) = x^{-2} \left(d_0 - d_3 x + \frac{1}{2} d_3 x^2 \right) + x^{-2} \left(d_3 x^3 - \frac{d_3}{4} x^4 + \frac{d_3}{4.5} x^5 - \frac{d_3}{4.5 \cdot 6} x^6 + \dots \right)$$

$$= d_0 \left(\frac{1}{x^2} - \frac{1}{x} + \frac{1}{2} \right) + d_3 \left(x - \frac{x^2}{4} + \frac{x^3}{4.5} - \frac{x^4}{4.5 \cdot 6} + \dots \right)$$

Take $d_3 = 0, d_0 = 1$:

$$y_2(x) = \frac{1}{x^2} - \frac{1}{x} + \frac{1}{2}$$

So if you take d_3 as 1 this is going to be like this. It is a series solution I have some only three terms as a solution plus already known solution together. This is your y_1 and y_2 plus y_1 plus y_2 as two linearly independent solutions. So you can also say these are $y_1 x$ and $y_2 x$. These are two linearly independent solutions. Here I removed this y_1 , okay, that is why it is only y_1 and y_2 . If you do not remove your y_1 so it is going to be both are series solutions. That is how you get, okay.

(Refer Slide Time: 46:19)

$$20d_3 + 4d_4 - 2d_4 - 10d_3 = 0 \Rightarrow 10d_3 + 2d_4 = 0 \Rightarrow d_3 = -\frac{1}{5}d_4 = \frac{d_5}{4.5}$$

$$y_2(x) = x^{-2} \left(d_0 - d_3 x + \frac{1}{2} d_3 x^2 \right) + x^{-2} \left(d_3 x^3 - \frac{d_3}{4} x^4 + \frac{d_3}{4.5} x^5 - \frac{d_3}{4.5 \cdot 6} x^6 + \dots \right)$$

$$= d_0 \left(\frac{1}{x^2} - \frac{1}{x} + \frac{1}{2} \right) + d_3 \left(x - \frac{x^2}{4} + \frac{x^3}{4.5} - \frac{x^4}{4.5 \cdot 6} + \dots \right)$$

Take $d_3 = 0, d_0 = 1$:

$$y_2(x) = \frac{1}{x^2} - \frac{1}{x} + \frac{1}{2}$$

So this is how you can solve in second order differential equation and the indicial equation has two roots and the difference is integer, okay, non zero integer. So here in this particular case you have seen first bigger root is 1. That will give me the series solution. Second solution we have chosen in a certain form and the difference is a non zero non integer, okay, so difference between the roots $k_1 - k_2$, k_1 is a bigger root, okay.

So when $k_1 - k_2$ is integer, sorry, it is a non zero integer, okay. This is the case for non zero integer so the bigger root will give me one series solution. Second solution in certain form when the difference between these two roots $k_1 - k_2$ is non zero integer which is k_1 is 1 and k_2 is minus 2 so the difference is 3 which is integer which is non zero. This case we have chosen special form for y_2 and substitute into the equation and get the unknowns.

So what we find is the second solution is actually simpler form $1 + x^2 - \frac{1}{2}x$, okay. So this is how you can get any second order equation when the indicial equation has roots and root difference is non zero integer, okay. So we can just meticulously follow this same method. You can find any (solu) equation in this particular case. Now we look at the (seve) another case. Now we have only one more case is left, okay.

That we will see in the next video that we consider an equation whose when you find the indicial roots, roots are same. So that means the difference between the roots is 0 but integer, okay. So that is away from the case 1 and case 2. So this is the case 3. You have actually equal roots, one will always give me first bigger root. Let us say bigger roots both are same.

So bigger root will give me one series solution and you have to find second linearly independent solution as special form which I explained earlier as a case 3. So now will demonstrate with an example in the next video.
