

**Differential Equations for Engineers**  
**By Dr. Srinivasa Rao Manam**  
**Department of Mathematics, IIT Madras**  
**Lecture 34**  
**Regular Sturm-Liouville Problem**

So in the last video we have seen (how to) we have seen the properties of symmetric or skew symmetric matrices and given matrix  $A$  if it's skew symmetric matrix we have seen certain properties the same way if you are given a matrix you can check  $A^* = A^T$  equal to  $A$  so if you check that if you verify that then it is skew symmetric so that's what you do to check the matrix is skew symmetric.

But for the differential equations if its general differential equation if it's a non linear it may not be select a general matrix so if it's a linear equation of second order that can always put in the this form that's kind of second order that can always put in the this form that's kind of a Hermitian form or self skew symmetric form ok, skew symmetric self adjoint or symmetric depends on a coefficient itself ok.

So we say that it's a we just show that it is Hermitian as an operator so we need second order we are only looking at the second order linear homogeneous equation so the operator if for the matrix we replacing with second order linear differential operator so which is almost Hermitian so we need to give certain boundary conditions to make it really Hermitian that's what we have seen so we will just saw we will do that today.

So we will just show that operator is actually self adjoint or Hermitian ok so we will look in to the equation again.

(Refer Slide Time: 01:45)

$$(M + \lambda q(x))y = a_2(x)y'' + a_1(x)y' + a_0(x)y = 0, \quad a < x < b$$

$$\text{where } M \equiv a_0(x) \frac{d}{dx} + a_1(x) \frac{d}{dx} + a_2(x)$$

Transform into  $Ly = \lambda y$

Assume that  $a_2(x) \neq 0, \forall x \in (a, b)$ .

$$y'' + \frac{a_1}{a_2}y' + \frac{a_0}{a_2}y + \lambda \frac{a_0}{a_2}y = 0$$

Let  $p(x) = e^{\int \frac{a_1}{a_2} dx}$

$$p(x)y'' + \frac{a_1}{a_2}p(x)y' + \lambda \frac{a_0}{a_2}p(x)y = 0$$

Additional notes on the right side of the slide:

- $Ax = \lambda x$  (with  $A = A^*$ )
- $Ly = \lambda y$  (with  $L = L^*$ )
- $B, C \in \mathbb{R}$  at  $a, b$
- $L$  is Hermitian

So we will just consider so this is the differential equation part so this is the differential equation this is replacing this is the operator A instead of ax you have lmy is here plus lambda sum function of xy so that I want to put it in this form ly equal to lambda y where I want to make this l is self adjoint Hermitian.

So what I did is in the last video we have seen that we calculated so we want to show if you want to show that l is Hermitian this is the definition we have seen.

(Refer Slide Time: 02:17)

check if  $L$  is Hermitian w.r. to this dot product.

$$\langle Lf, g \rangle = \langle f, Lg \rangle, \quad \forall f(x) \text{ \& } g(x)$$

$$L.H.S = \int_a^b w(x) Lf(x) \overline{g(x)} dx = \int_a^b Lf(x) w(x) \overline{g(x)} dx = - \int_a^b \frac{1}{w(x)} \left[ \frac{d}{dx} \left( p(x) \frac{df}{dx} \right) + q(x) f(x) \right] w(x) \overline{g(x)} dx$$

$$= - \int_a^b \left( \frac{d}{dx} \left( p(x) \frac{df}{dx} \right) + q(x) f(x) \right) \overline{g(x)} dx.$$

So this dot product should be same for every function  $f$  and  $g$  you take any functions  $f$  and  $g$  this is what this should be satisfied so we have taken the left hand side and we also have seen what is the dot product once you know what is the differential equation.

So once you know what is this  $L$  which is this ok so once you know what is  $L$  we defined the dot product in this fashion ok.

(Refer Slide Time: 02:43)

$\langle f, g \rangle := \int_a^b w(x) f(x) \overline{g(x)} dx \checkmark$

check if  $L$  is Hermitian w.r. to this dot product.

$$\langle Lf, g \rangle = \langle f, Lg \rangle, \quad \forall f(x) \text{ \& } g(x)$$

$$L.H.S = \int_a^b w(x) Lf(x) \overline{g(x)} dx = \int_a^b Lf(x) w(x) \overline{g(x)} dx = - \int_a^b \frac{1}{w(x)} \left[ \frac{d}{dx} \left( p(x) \frac{df}{dx} \right) + q(x) f(x) \right] w(x) \overline{g(x)} dx$$

$$= - \int_a^b \left( \frac{d}{dx} \left( p(x) \frac{df}{dx} \right) + q(x) f(x) \right) \overline{g(x)} dx.$$

So this is the dot product we have defined with respect to this dot product we want to check whether  $L$  is Hermitian or not that means we want to verify whether this equality is true or not so we calculate the left hand side so which is like this if you so we have seen that it is actually this.

(Refer Slide Time: 03:05)

$$\begin{aligned}
 &= - p(x) \frac{df}{dx} \bar{g}(x) \Big|_a^b + \int_a^b p(x) \frac{df}{dx} \frac{d\bar{g}}{dx} dx - \int_a^b q(x) f(x) \bar{g}(x) dx \\
 &= - p(x) \frac{df}{dx} \bar{g}(x) \Big|_a^b + f(x) p(x) \frac{d\bar{g}}{dx} \Big|_a^b - \int_a^b f(x) \frac{d}{dx} \left( p(x) \frac{d\bar{g}}{dx} \right) - \int_a^b q(x) f(x) \bar{g}(x) dx \\
 &= \int_a^b p(x) \left[ f(x) \frac{d\bar{g}}{dx} - \frac{df}{dx} \bar{g}(x) \right] dx - \int_a^b f(x) \left[ \frac{d}{dx} \left( p(x) \frac{d\bar{g}}{dx} \right) + q(x) \bar{g}(x) \right] dx
 \end{aligned}$$

So now next step is just use integration by parts bring this differential operator so integration by parts basically what it does is simply take the derivatives on to the other function if you have a derivative of f into g as a integrant so by integration by parts what it does is I basically take the derivatives on to the other function so that's what we do now ok, so here so you have so you can do the integration by parts.

So just by integration by parts what we get is integral so you have a  $p(x) df$  by  $dx$  so that's anti derivative into  $\bar{g}$  of  $x$  so this you take limits  $a$  to  $b$  minus minus plus that's going to be  $a$  to  $b$  what you have is  $p(x)$  only first term I am doing so  $p(x) df$  by  $dx$  into  $\bar{g}$  of  $x$   $dx$  ok so this what you have after first integration and the other one you right as it is the other term that is simply integral  $a$  to  $b$   $q(x) f(x)$  into  $\bar{g}$  of  $x$   $dx$ .

So now what happens is so this you cannot do unless you don't know anything about  $f$  and  $g$  so the leave it as it is this one so this is minus  $p(x) df$  by  $dx$  into  $\bar{g}$  of  $x$  at  $a$  to  $b$  plus one more integration by parts here so if you do that what you get is simply anti derivative of this is one function  $p(x)$  into  $\bar{g}$  of  $x$  is another function so you think of this  $p(x)$  into  $\bar{g}$  of  $x$  is another function and  $df$  by  $dx$  is one function.

So if you do the integration by parts here so you get  $f(x)$  and you have  $p(x) \bar{g}$  of  $x$  sorry wait wait so when you do the integration by parts what you get is  $df$  by  $dx$  (and you have  $a$ ) you need

to differentiate other part that is actually giving  $d/dx$  of  $px$  into  $g$  bar of  $x$  this is what you have the first integration by now what you have is you do this, this is one function and this is another function ok, so if you do this what you get is .

$Fx$  and you have the derivative so  $d/dx$  of  $px$ , just a minute I think I made a mistake this is what is  $px$   $df$  by  $dx$   $gf$ , this is the mistake so wait so actual thing is if you do the integration by parts  $px$   $df$  so you have  $px$   $df$  by  $dx$  you have to differentiate this  $g$  bar so this that will be  $g$  bar by  $dx$  ok  $g$  bar derivative so that is what is missing so this is what you have so this one now you think of this is one function, other function is  $px$  into  $dg$  bar by  $dx$ .

So if you do that integration by parts you have  $fx$  into  $px$   $dg$  bar by  $dx$  this you take the limits from  $a$  to  $b$  and you get minus sign and now we have integration from  $a$  to  $b$  and what you have is  $fx$  and the derivative of  $px$  into  $dg$  bar by  $dx$  so you have a  $d/dx$  of  $px$   $dg$  bar by  $dx$  so this is what you have ok, so this into this minus this is as it is you have  $qx$   $fx$   $g$  bar of  $x$   $dx$  so this is what you have so this is equal to.

So if you can put all these boundary terms these are the boundary terms first two so this you can  $px$  is common  $px$  times so what you have is  $fx$   $dg$  bar by  $dx$  minus  $df$  by  $dx$  into  $g$  bar of  $x$  so this is what this for this whole thing you take a limits  $x$  is from  $a$  to  $b$  so this at  $b$  this whole quantity at  $b$  minus whole quantity at  $a$  and this two terms I can put it like that and then what you have is now this you can put it together so this is from  $a$  to  $b$   $fx$ ,  $fx$  is common.

So I am combining this whole thing together so this will give me  $d/dx$  of  $px$   $dg$  bar by  $dx$  plus  $g$  bar of  $x$   $qx$   $g$  bar of  $x$  so this is what you have for this function

(Refer Slide Time: 08:27)

The image shows a whiteboard with handwritten mathematical equations. At the top, there are some faint notes:  $\int_a^b p(x) [f' - f'g] dx + \int_a^b f(x) \overline{Lg(x)} \omega(x) dx$ . Below this, the main equation is:
$$\langle Lf, g \rangle = \underbrace{[p(x)(f' - f'g)]_a^b}_{=0} + \langle f, Lg \rangle$$
To the right of this equation, it says  $L\bar{g} = \overline{Lg}$ . Below that, there is a small diagram of a number line with points  $a$  and  $b$  marked, and a horizontal line segment between them.

So what is this one this is exactly so what is this one this is actually equal to  $p(x)$  I will write  $f$  into  $g$  bar dash minus  $f$  dash  $g$  bar ok, so from  $a$  to  $b$  the limits ok so this is what you have minus integral  $a$  to  $b$   $f(x)$  into what is this one, this is actually plus and with the minus if you want to put take this minus inside.

For the whole thing ok minus and minus and if you look at this one this is exactly your  $lg$  ok so  $lg$  is that is actually  $lg$  bar ok  $\times dx$  ok it's not actually  $lg$  so you have to divide with one by  $\omega(x)$  once you have one by  $\omega(x)$  you have to multiply also ok so with one by see you have this operator one by  $x$  one by  $w(x)$  minus  $d/dx$  of this whole thing up to here will give me this and what you have is  $w(x)$  that's a weight function  $dx$ .

So this is exactly so this is nothing but  $p(x)$  this is fine so  $fg$  bar dash minus  $f$  dash  $g$  bar this whole thing from  $a$  to  $b$  ok  $x$  is from  $a$  to  $b$  so just limits plus this is nothing but  $fg$  because this  $L$  is actually differential operator, so differential equation with the real coefficient so those are for those functions  $a_1 a_2 a_3$  or  $p p q r pq$  right you have  $pqw$  is all real valued functions there also bar that doesn't make them anything so  $lg$  bar is actually  $lg$  whole bar ok.

So if you put it thing of like that so this is  $lg$  bar so that is same as  $lg$  bar so that is same as  $lg$  bar actual this is same as  $lg$  whole bar so that will give you this dot product so you see that (second ord) if you start with the second order equation that is lhs is left hand side is  $Lfg$  is actually same

as this one lfg so this dot product you want this to be this ok for a second order differential equation linear second order differential equation.

So for that I have this boundary terms unless I make them zero I cannot get, I cannot make this second order differential equation as skew symmetric or Hermitian ok so it will be Hermitian if I can remove this boundary terms ok, so for that what we do is we take this system this equation differential equation and I define certain boundary condition so I have a to b that's the domain so I have only finite domain it a b this is the boundary.

A and b these points are boundary points so at these points you give the boundary conditions so that I can make so if what kind of boundary conditions that will make this quantity zero.

(Refer Slide Time: 12:00)

$$\langle Lf, g \rangle = \left[ p(x) \left( f' \bar{g}' - f \bar{g}'' \right) \right]_{x=a}^x + \langle f, Lg \rangle$$

Regular Sturm-Liouville problem:

$$Ly = \lambda y, \quad L = -\frac{1}{w(x)} \left[ \frac{d}{dx} \left( p(x) \frac{d}{dx} \right) + q(x) \right]$$

where  $p(a) \neq 0, p(b) \neq 0$ . Assume that

$$p(x) > 0, x \in (a, b), q(x), w(x) > 0$$

Boundary conditions:

$$\begin{cases} \alpha_1 y(a) + \alpha_2 y'(a) = 0 \checkmark \\ \beta_1 y(b) + \beta_2 y'(b) = 0 \checkmark \end{cases} \quad \text{Not both } \alpha_i \text{'s or } \beta_i \text{'s are zero}$$

So let us start with regular Sturm Liouville system, so if I do this regular Sturm Liouville so there are different cases different boundary conditions we will give you different Sturm Liouville problems ok so let's see usual one - that is our regular Sturm Liouville system. Regular Sturm Liouville problem ok?

So problem so here what you have is you have this  $ly$  equal to  $\lambda y$  ok so where  $l$  is minus one by  $wx$  ddx of  $px$  ddx is operator ok minus plus  $qx$  so this is what is your  $l$  so if  $p$  is not zero  $p$  never be zero by the way  $bp$  if what is  $p$ ?  $p$  is actually equal to exponential of integral a one by a

so this will never be zero so you can see that this will never be zero wherever  $x$  is there  $x$  is in  $ab$  open interval ok.

So in the open interval  $p$  of  $x$  will never be zero so if  $p$  of  $x$  is non zero for every  $x$  in the open interval anywhere its non zero so include the points  $ab$  ok then its regular ok so if you can write like this where it's a regular Sturm Liouville system if where a  $p$  of  $a$  is non zero and  $p$  of  $b$  is also non zero ok so in this case we say that this is regular Sturm Liouville system  $q$  what is  $q$ ?  $Q$  Is actually  $a^2$  by  $a$  not into  $px$ .

So  $a^2$  can be so it's  $a^2$  of  $a^2$  by  $a$  not that can take both positive and negative values so that means  $qx$  can take both positive and negative it can take any value but  $p$  is always positive,  $w$  you want it to be positive and for the reason you will know if it is not positive why it will has to be positive ok so you will see the reasons so you will see that  $px$  is always positive ok  $x$  belongs to  $ab$  and you don't know here  $p$  of  $ab$  ok.

So only in the open interval you know that it is a non zero ok now what happens  $pq$   $q$  can be anything  $q$  can be anything so I am not imposing anything you see  $qp$  is always positive  $q$  is this  $wx$  is also you need to be assume that is positive ok so need to be positive this is you can assume that, we assume that  $w$  is always positive reason is if it is negative what happens to this dot product if you look at the dot product which you define if  $w$  is negative.

When you take the same function  $g$  equal to  $f$  what you have  $f$  square into  $wx$  the integral constant so dot product you want it always to be positive quantity ok so but that is going to be negative if  $w$  is negative so for that reason we can always assume that  $w$  is zero so you for your problem so all the differential equations with you know when you take this right hand side this third function with the parameter so you always assume that  $a^3$  is always positive ok.

So it takes the positive values  $a^3$  by  $a$  not will always be positive function ok that is your  $w$ , so with this then it say that is the Sturm Liouville regular Sturm Liouville problem if mainly  $px$  is positive so in this case the boundary conditions you make this regular Sturm Liouville problem the boundary conditions are like this you consider some  $\alpha_1$   $y$  is the unknown function so  $y$  at  $a$  plus  $\alpha_2$   $y$  dash at  $a$  equal to zero so this is the one boundary condition ok.

So these are the boundary conditions, what are the boundary conditions we have this is one at a so other one is you call this some beta one y at b so at b I am giving beta 1 beta 2 values and y at b equal to zero if both alpha 1 and alpha 2 are zero so there is no boundary conditions so at least one of them not both of them are zero ok so not both alpha I's or Beta I's are zero ok so you can say that this is not both the alpha I's both the beta I's are zero.

Otherwise there is no boundary condition there so these are the boundary conditions if it prescribe what happens to this term so now we always look at this term I want to make this (I defy) I give the boundary conditions regular case these are the boundary conditions because px is non zero at ab so I have to make this quantity ok so this quantity I want to make it zero so if f and g are two solutions of this system ok.

You take f and g are two solutions ok, so if you have f and g are two solutions corresponding to some lambda ok.

(Refer Slide Time: 17:41)

Boundary conditions

$$\begin{cases} \alpha_1 y(a) + \alpha_2 y'(a) = 0 \checkmark \\ \beta_1 y(b) + \beta_2 y'(b) = 0 \checkmark \end{cases}$$

Not both  $\alpha_i$ 's or  $\beta_i$ 's are zero

System

$$\begin{cases} Ly = \lambda y, & x \in (a, b), & p(x) = p'(x) \neq 0 \\ \alpha_1 y(a) + \alpha_2 y'(a) = 0 \\ \beta_1 y(b) + \beta_2 y'(b) = 0 \end{cases}$$

Let  $y_1(x)$  &  $y_2(x)$  be two different solutions of the system

---

$\alpha_1 y_1(a) + \alpha_2 y_1'(a) = 0$	$\alpha_1 y_2(a) + \alpha_2 y_2'(a) = 0$
$\beta_1 y_1(b) + \beta_2 y_1'(b) = 0$	$\beta_1 y_2(b) + \beta_2 y_2'(b) = 0$

What happens to that so we will see with these boundary conditions the moment you give this boundary conditions now this equation ly with this boundary conditions let's write this regular Sturm Liouville again ly is lambda y and these are your alpha 1 y at a plus alpha 2 y dash at a equal to zero and beta 1 y at b plus beta 2 y dash at b equal to zero.

So this is a regular Sturm Liouville system  $x$  in  $ab$  and you have a  $p$  or  $at a$  and  $p$  at  $b$  are non zero so this is the condition so these are this is the regular Sturm Liouville system so once you have this so I want to see any solutions of this system this problem any solutions if you put it here so that is what right you take any solutions  $f$  and  $g$  and you take this operator  $lfg$  has to be  $flg$  any functions that are the solutions part of the solutions of this equation ok.

So let us consider two solutions let  $y_1$  of  $x$  and  $y_2$  of  $x$  be two different solutions of the system, system means differential equation at the boundary condition this is your system ok, regular Sturm Liouville system so if you take that so what you have is  $y_1$  satisfying this equation and these boundary conditions if you apply that boundary conditions  $\alpha_1 y_1$  at  $a$  plus  $\alpha_2 y_1$  dash at  $a$  equal to zero.

And similarly  $\beta_1 y_1$  at  $b$  plus  $\beta_2 (y_2 y_1 \text{ at}) y_1$  dash at  $b$  equal to zero, and similarly you have  $y_2$  is also satisfying other  $y_2$  is also satisfying the equation  $ly_2$  equal to  $\lambda y_2$  ok for some  $\lambda$  ok so I am not saying that  $y_1$  and  $y_2$  are two solutions for the same  $\lambda$  so for some  $\lambda$  these are the solutions ok, for some parameter values of  $\lambda$   $y_1$  is one solution but satisfying the same boundary conditions  $y_2$  is also satisfying for some  $\lambda$ .

Sum of the equation but the same boundary conditions so if  $y_2$  is having satisfying the same boundary conditions you have  $y_1 \alpha_1 y_2$  at  $a$  plus  $\alpha_2 y_2$  dash at  $a$  is zero and similarly  $\beta_1 y_2$  at  $b$  plus  $\beta_2 y_2$  dash at  $b$  equal to zero ok.

(Refer Slide Time: 20:34)

The image shows a handwritten derivation in a software window titled "Differential Equations for Engineers: 10-04-2017 - Windows Journal". The derivation starts with two homogeneous equations at points  $a$  and  $b$ :

$$\alpha_1 y_1(a) + \alpha_2 y_1'(a) = 0 \quad \alpha_1 y_2(a) + \alpha_2 y_2'(a) = 0$$

$$\beta_1 y_1(b) + \beta_2 y_1'(b) = 0 \quad \beta_1 y_2(b) + \beta_2 y_2'(b) = 0$$

These are then combined into a matrix equation:

$$\begin{bmatrix} y_1(a) & y_1'(a) \\ y_2(a) & y_2'(a) \end{bmatrix} \begin{bmatrix} \alpha_1 \\ \alpha_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Since the coefficient matrix is not the identity matrix, the determinant must be zero:

$$\det \begin{bmatrix} y_1(a) & y_1'(a) \\ y_2(a) & y_2'(a) \end{bmatrix} = 0$$

Similarly, at point  $b$ :

$$\det \begin{bmatrix} y_1(b) & y_1'(b) \\ y_2(b) & y_2'(b) \end{bmatrix} = 0$$

The final result is the Wronskian determinant:

$$\Rightarrow W(y_1, y_2)(a) - W(y_1, y_2)(b) = 0$$

Now you consider these two equations together, these two equations if you take together so you write it together so consider these two or these two ok so either this these two or these first two solutions so if you consider.

Consider  $\alpha_1 y_1 + \alpha_2 y_1' = 0$  similarly  $\alpha_1 y_2 + \alpha_2 y_2' = 0$  if you consider these two equations you get this one so you know that we have seen we have already assumed in the boundary conditions that not both  $\alpha$ 's are zero so that means for this is like a system  $y_1 a y_1' a$  ok and  $y_2 a y_2' a$  this is the matrix and this is your unknowns  $\alpha_1 \alpha_2 = 0$ .

So this is like you have system  $ax = 0$  and I know that  $\alpha_1 \alpha_2$  is non zero ok  $\alpha_1 \alpha_2$  as a vector ok is non zero so this is you we know this is the assumption we made not both  $\alpha_1 \alpha_2$  are zero since this is non zero then the determinant has to be zero because this is the homogenous  $ax = 0$  when you have a non zero solution that means when you have non zero solution determinant of  $a$  has to be zero.

So that is that means the determinant since this is this you have  $y_1$  at a  $y_1'$  at a and  $y_2$  at a  $y_2'$  at a so this determinant has to be zero we have this so what is this determinant this is nothing but  $y_1$  at a  $y_2'$  at a minus  $y_1'$  at a  $y_2$  at a ok so this is equal to zero so this is exactly

what you have here so  $p$  at  $a$  say the lower limit  $p$  at  $a$  that is anyway not zero and what you have is  $f$  and  $g$  are two solutions of this system ok.

If you take  $f$  is  $y_1$   $g$  as  $y_2$  so what you have is so this derivative so you can see that this derivative this is nothing but  $y_2$  is if  $y_2$  is a solution  $\bar{y}_2$  is also a solution ok because the homogeneous equation so  $\lambda$ ,  $\lambda$  is always real ok so you can take think of this once you make this problem  $\alpha_1$   $\alpha_2$  are real ok  $\alpha$  I's and  $\beta$  I's are real so if you take  $y_1$  as one solution  $y_2$  is also another solution.

$\bar{y}_2$  is also a solution satisfying that corresponding to some  $\bar{\lambda}$  ok if  $y_2$  is a solution of this system what you have is  $\bar{y}_2$  is a solution of  $\bar{L}y_2 = \bar{\lambda}$  some  $\bar{\lambda}$  ok if  $y_2$  is a solution for some  $\lambda$   $\bar{y}_2$  is a solution for some  $\bar{\lambda}$  for the same  $\lambda$  ok for the same and so conjugate of the same  $\lambda$  so with that so it's equation is generally satisfied and the boundary conditions we always assume that they are real.

So if because they are real it satisfies same boundary conditions by  $\bar{y}_2$  also so you can think of  $y_2$  as  $\bar{y}_2$  as well so you can think of  $y_1$  and  $\bar{y}_2$  be two solutions ok  $y_1$  and  $\bar{y}_2$  be two solutions you can think then you have this one you can make bars here ok because  $\alpha_1$   $\alpha_2$  are real so you don't have  $\beta_1$   $\beta_2$  all real so this you can put it as bars so if you do that so what you have is these are bars so these are bars.

So that exactly what you have in a form so this is  $y_2$   $\bar{y}_2$  so this is exactly the lower limit of this special term where  $p$  at  $a$  when you put  $x$  equal to  $a$   $f$  and  $g$  are two solutions  $f$  and  $\bar{g}$  two solutions here I have taken as  $y_1$  and  $\bar{y}_2$  and the lower limit will be exactly will become zero because this is zero this implies  $p$  at  $a$  into  $y_1$  at  $a$  into  $\bar{y}_2$  dash at  $a$  bar minus  $y_1$  dash at  $a$   $\bar{y}_2$  at  $a$  bar this is zero ok so exactly so the same thing with these two other equations.

Do the same thing with the other equations you consider them put it as a system since  $\beta$  I's are different  $\beta$  I's both are non zero ok that means instead of  $\alpha_1$   $\alpha_2$  you have  $\beta_1$   $\beta_2$  so you do the same thing what you get is you have  $\beta_1 y_1$  at  $b$  plus  $\beta_2 y_1$  dash at  $b$  is zero this is one equation other one equation is  $(y_1 b) y_2 b$  bar plus  $\beta_2 y_2$  dash  $b$  equal to zero so if you consider this and you can see that since  $\beta_1$  and  $\beta_2$  is not actually zero zero.

So what you have is a determinant of this matrix  $y_1 b$   $y_1$  dash  $b$   $y_2 b$  bar and  $y_2$  dash  $b$  bar this determinant has to be zero so what is this determinant? This is that is simply  $y_1$  at  $b$  into  $y_2$  dash at  $b$  bar minus  $y_2$  at  $b$  bar  $y_1$  dash at  $b$  so this has to be zero you can multiply with  $p b$  that is also zero.

(Refer Slide Time: 26:29)

The image shows a whiteboard with the following handwritten mathematical derivations:

$$\Rightarrow [y_1(a) y_2'(a) - y_1'(a) y_2(a)] = 0$$

$$\Rightarrow p(a) [y_1(a) y_2'(a) - y_1'(a) y_2(a)] = 0 \checkmark$$

$$p(a) \left[ f \bar{g}' - \bar{g} f' \right]_a^b = 0, \text{ for all solutions } f \text{ \& } g \text{ of the regular S-L system.}$$

$$\Rightarrow \langle Lf, g \rangle = \langle f, Lg \rangle, \forall f, g$$

$$\Rightarrow L \text{ is Hermitian or self-adjoint or skew-symmetric.}$$

So with this these are simply lower and upper limits of this special term which you have so that makes it zero.

So if you consider this special regular Sturm Liouville system with these boundary conditions what you found is that special term  $p x$  and  $f$  and  $g$  are two solutions any solutions of this system  $f g$  bar  $f g$  dash bar I will write  $f g$  dash bar minus  $g f$  dash bar right that is zero  $f$  dash  $g$  bar  $f g$  bar dash ok. So this is actually should be  $g$  bar dash and  $g$ ,  $g$  bar  $f$  dash so that is  $g$  bar  $f$  dash this term and you multiply and you put this limits it is zero ok.

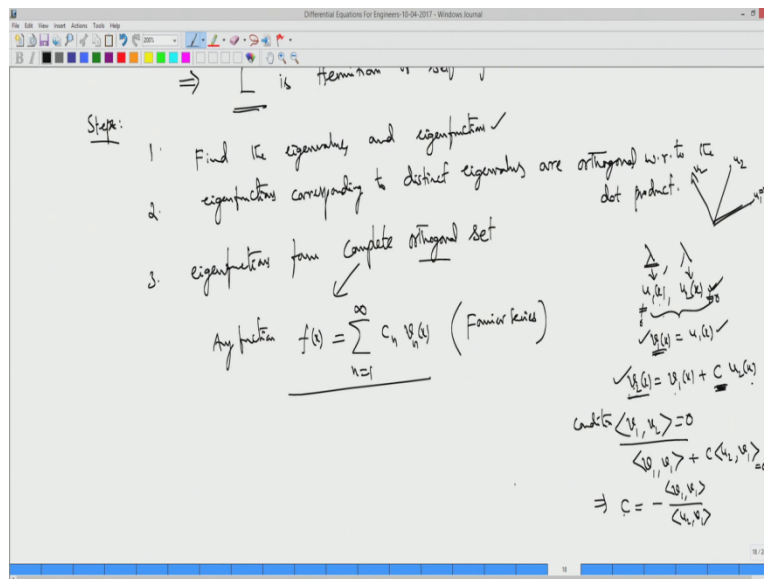

For every  $f$  for every solutions of or rather for all solutions for all solutions  $f$  and  $g$  of the regular Sturm Liouville system regular sl system this is wide I right now onwards ok sl system so if you have a two solutions sl system for some  $\lambda$ ,  $\lambda$  is a parameter for some  $\lambda$  if you take what you get is that special term will become zero so this will simply gives you  $lfg$  is nothing but  $flg$  that makes it zero ok.

So that makes it this is to for every f and g solutions of this system so that makes it L is Hermitian so this implies L is Hermitian or self adjoint or skew symmetric. And you are not in the finite dimensional you are in the infinite dimensional space ok you call it that space as  $\mathbb{R}^n$  there you have vectors are only, you have only n linearly independent vectors here you can have infinite many linearly independent functions in the as a functions.

If you there at the function space linearly independent vectors, vectors are functions those vectors are those functions are infinitely many ok linearly independent functions are many because  $1 \times x$  square you consider these are the solutions of you can just think ok for some operator for some lambda these are the solutions where these will give these kind of boundary conditions they are all solutions.

That will make it they form infinite dimensional space ok so in this case so you have call this operator is self adjoint then we don't prove this properties in the infinite dimensional we just limit it so we just analog ally we take these properties for granted so what we have shown that the properties for the for the matrices when L is a matrix a ok.

(Refer Slide Time: 30:00)

So what we have is once you have this you find what is the next step is find all the eigen values. Find the eigen values and eigen functions vector is actually here function so I can call this eigen functions that is what is the step ok so the next steps are like this so step first step is this find the

eigen values and eigen functions second one is and then you can easily see that the property so different different eigen values distinct eigen values gives eigen functions this is the property which we assume ok.

Eigen functions corresponding to distinct eigen values are orthogonal ok with respect to the dot product that we define for the operator  $L$  what we have define this is exactly what we define so if you have a differential equation with this operator ok so if you have this operator so you have this inner product they have with this dot product ok so with respect to this dot product these functions are orthogonal so that's what you have.

So once you have so your job is to find is eigen values and eigen functions then you can say that these are all different eigen values, different eigen values if you take corresponding eigen functions they are actually orthogonal if they are not suppose some eigen values are repeated or for some eigen values repeated you may have two functions ok two eigen functions you may have because the second order maximum you will have two linearly independent solutions.

We know any second order equation you can have maximum two linearly independent solutions so give fix your lambda you may have two linearly independent solutions for that system ok with the boundary conditions so in such a case you may have maximum two linearly independent solutions for the corresponding eigen value so that means you have two eigen functions maximum because it's the second order for an eigen value.

So if they are not orthogonal obviously they are, for the same eigen value you have eigen functions if I call so let's call this some  $v_1(x)$  ok  $v_2(x)$  are two eigen functions, if these are two eigen functions you cannot expect because they are from the same eigen value these are eigen functions corresponding to the same eigen value, they are linearly independent that much issue because that's how find these two ok you are simply go to solve the equation.

And with boundary conditions with by fixing this lambda so you looking for non zero solutions these are the non zero solutions just like what you do for the matrix, for the matrix how do you find the eigen vectors you fix that lambda you calculate all the solutions non zero solutions of that a minus lambda  $ix$  equal to zero so by doing that if you look for non zero solutions they are eigen vectors so you are doing the same thing here.

You fix this  $\lambda$  in  $Ly = \lambda y$  and the boundary conditions you calculate the solutions non zero solutions if you can get two solutions ok they are they are certainly linearly independent solutions ok two non zero linearly independent solutions and you cannot say they are orthogonal ok what we did if it is a repeated root but that means I have two repeated  $\lambda$  I have two eigen functions corresponding to this this.

So in such a case you make them orthogonal by the Gram-Schmidt process by redefining  $y$  to  $x$  as you can make them ok  $v$  to  $x$  into the process so this  $v_1$  of  $x$  plus so you call this something like  $v_1$  I want to if you make orthogonal I call this let's call this  $u_1$  and  $u_2$  and you how do you make this Gram-Schmidt orthogonal process you I want to make them orthogonal like this  $v_1$  is  $u_1$  of  $x$  similarly  $v_2$  of  $x$  you take  $u_1$  that is actually  $v_1$ .

I define  $v_1$  plus some constant times  $u_2$  these are known  $u_1$   $u_2$  are known so I choose my  $c$  in such a way that  $v_1$   $v_2$  are orthogonal this is the condition  $v_1 \cdot v_2$  with respect to this that inner product is that dot product is zero ok so with this condition you put this condition that makes it  $v_1 \cdot v_1$  this dot product plus  $c$  times  $u_2$  into  $v_1$  this has to be zero, so that makes it that will give you minus  $v_1 \cdot v_1$  by  $u_2 \cdot v_1$  so  $u_1 \cdot v_1$  is known right  $u_2 \cdot v_1$ .

What is the right hand side  $v_1 \cdot u_2 \cdot v_1$  so only  $u_2$  and  $v_1$ ,  $v_1$  is nothing but  $u_1$ ,  $u_1$   $u_2$  are known so you can make put this  $c$  here and that is your  $v_2$  so now  $v_1$   $v_2$  are orthogonal and  $v_2$  is nothing but linear combination of these functions  $u_1$  and  $u_2$  so they are also linearly independent so you have two linearly independent solutions but now they are orthogonal so something like if you have two vectors in the plane you are given like this you can make them orthogonal ok.

So by this is like  $u_1$   $u_2$  you make them actually you are taking  $u_1$  as  $v_1$  so this itself is  $v_1$  now you make orthogonal to this, this is your  $v_2$  that's what you did ok so I explained earlier so you have you can make them orthogonal if they are not if you have two linearly independent eigen functions ok so what is the next step what is the other properties which you have seen for the matrices which are skew symmetric Hermitian matrices.

Eigen values are eigen vectors and any vector in that space or functions actually I can write in terms of these eigen vectors ok actually all these eigen vectors for the matrix you have if it is  $n$  by  $n$  matrix you have only you will get  $n$  linearly independent eigen vectors that is not two for

the general matrix ok if it is Hermitian you can always get  $n$  linearly independent eigen vectors ok some of them may not be orthogonal so you can make them orthogonal.

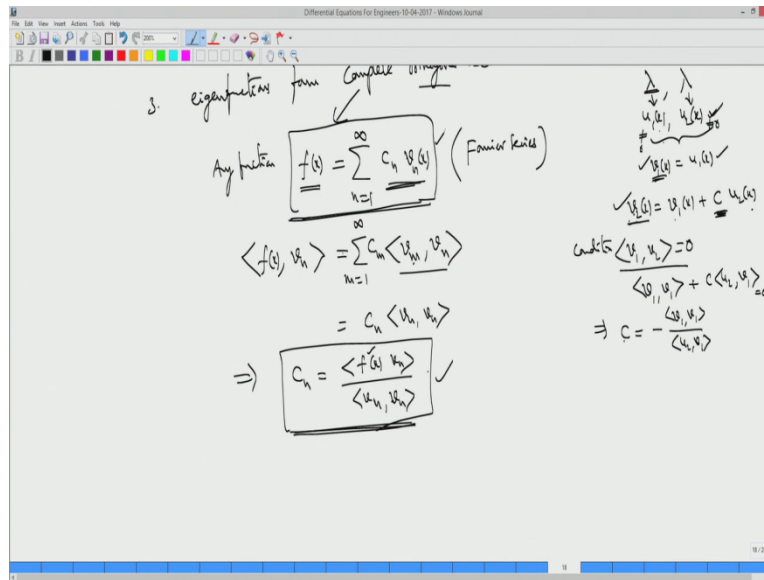

By this Gram Schmidt process so finally you get  $n$  linearly independent orthogonal eigen vectors so here also you get the same so all these functions you get once you get all these eigen functions they and if they are not orthogonal once you fix  $\lambda$  if you get two linearly independent solutions make them orthogonal by the Gram Schmidt process finally ultimately you get for different  $\lambda$  values you collect all these are actually orthogonal functions.

So you have  $n$  linearly independent for the space  $\mathbb{R}^n$  in the finite dimension here you have infinite that is the meaning ok so once you have  $n$  linearly independent eigen vectors in  $\mathbb{R}^n$  any vector I can write it in terms of them so here also (any function now any function) any reasonable function ok I can write in terms of these eigen functions that is called complete so these eigen functions form a complete set.

Complete means any function I can write it in terms of them that is exactly over Fourier series ok so I will write just write like that so eigen functions form complete orthogonal set so orthogonal we have already seen how to get them, this complete means this means any function let's say  $f$ ,  $f$  I can write in terms of  $c_n$   $n$  is now from one to infinity because you have infinitely many eigen functions  $c_n u_n$  so let's call them, once I make them  $v_n$  I call them  $v_n$  of  $x$  ok.

So this is what you get this is the actually Fourier series what you see Fourier series you get a different equation you will get a different Fourier series.

(Refer Slide Time: 38:47)

So how do I find my  $c_n$ ,  $c_n$ s I can easily find you know the inner product which are orthogonal so you multiply  $v_n$  both sides with respect to this inner product you make that integral as in the (inner product) as in the dot product ok the dot product you defined as an integral.

So that you make use of that dot product so if you do simply if you have  $f$ ,  $f$  is any function you multiply  $v_n$  here and you multiply that weight function you integrate both sides from  $a$  to  $b$  if you do that what you get is this dot product which is and you see that because  $v_n v_n$  let's so you check the index this is only from  $i$  is from  $n$  from right it from  $m$  is from one to infinity  $c_m v_m$  this is going to be  $v_m$  and you are making a dot product with  $v_n$ .

And these are all orthogonal if  $n$  is  $m$  is not equal to  $n$  it will be zero what is contribute here only  $c_n v_n v_n$  so this will determine  $c_n$ ,  $c_n$  is  $f v_n$  by  $v_n v_n$  so these are your fourier coefficients ok so these are your fourier coefficients that's the fourier transform if you define if you have a signal time signal you first define fourier transform as a different frequencies, this will give you those fourier coefficients ok so frequencies are 1, 2, 3 and so on.

So these are ok so you make a frequencies this is actually fourier transform ok different frequencies these are fourier coefficients and you correspondingly you have this  $c_n v_n$  is a fourier so any signal  $f(x)$  I can write in terms of frequencies different frequencies you break it the

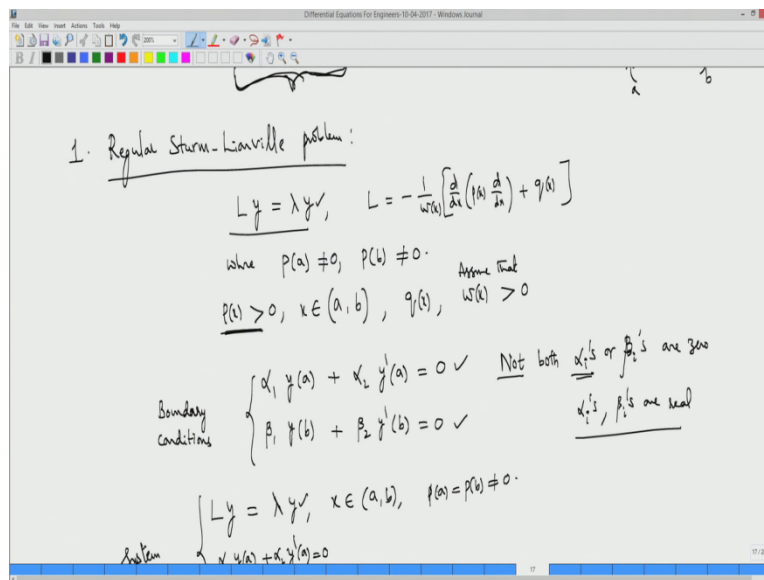

signal you break it into different frequencies so these are your frequencies you can define given its time signal you can get this fourier transform and this is a kind of inverse transform.

If you know if you have given signal here  $f(x)$  you get a fourier transform that is of fourier signal fourier transform and using them you can get back so if you are given like this all these frequencies you can get back your signal from this inverse transform.

That's fourier series ok, so this is what you see from the Sturm Liouville any Sturm Liouville problem and so there you have a equation so you have a differential equation.

So given a differential equation with 1 second order equation for different equation you have a different fourier series so you have a kind of infinitely many fourier series ok for a infinite equations you can create any equation you can get the such fourier series ok as what you will learn ok

(Refer Slide Time: 41:40)

So we will see this is what I have say so if you have a second order equation with  $p$  of  $a$  and  $p$  of  $b$  is non zero and these are the boundary condition match.

That special term is zero so that (operator) differential operator is Hermitian so that you can conclude the properties using the properties of this Hermitian operator ok analogous to the Hermitian matrices you can conclude that you can actually get any function you can write in

terms of those eigen functions ok so these things are useful when you are solving a certain pde's partial differential equations in certain simple domains ok.

By separation of variables method when you do when you are trying to solve the partial differential equations in some certain domains what we do is we extract we try to make the partial differential equation into an ordinary differential equation problem so actually is strictly speaking is you make it a Sturm Liouville problem you extract a Sturm Liouville problem and the you make use of this and finally solve the partial differential equation.

That is where these Sturm Liouville problems are useful ok you can also see that different fourier series you can get out of this Sturm Liouville theory ok so this is only case one which you have seen for the regular Sturm Liouville system so this is type one like this you can get different things so what else, how else what is the next thing is next case is how do I see how do I give a different boundary conditions when  $p$  of  $a$  is zero or  $p$  of  $b$  is zero or both are zero ok.

Either  $p$  of  $a$  is zero or  $p$  of  $b$  is zero or (both of) both  $p$  of  $a$  and  $p$  of  $b$  are zero in that case what happens ok if  $p$  of  $a$   $p$  of  $b$  is zero so that is one system that is or both are zero that is called singular Sturm Liouville system another case is  $p$  of  $a$  equal to  $p$  of  $b$  ok in that case what you see is you can look for some periodic Sturm Liouville system so we will see these two cases how to make second order homogeneous equations.

So that operator  $L$  as a Hermitian with the boundary condition so we will try to provide the boundary conditions in such cases ok depending on what is  $p$  of  $a$   $p$  of  $b$  how the  $p$  of  $a$  and  $p$  of  $b$  ok if they are non zero it's a regular if they are same  $p$  of  $a$  equal to  $p$  of  $b$  then you have periodic system if  $p$  of  $a$  equal to zero or  $p$  of  $b$  equal to zero or both of them are zero that is one case that is singular Sturm Liouville system so in that case how to make this special term zero.

So that the operator corresponding the actual differential operator  $L$  is Hermitian so that properties of these operator can be used to get the fourier series ok that's what we will see so we will see the next two cases and the next video and then we will give different examples in each case if it's a regular so if you have a example for the regular system so get the eigen values and eigen functions so whatever we planned here.

So all these three steps we will see we take it and just conclude ok so that's what we will do so we will see this these next two cases how to make the second order differential operator self adjoint or Hermitian ok so thank you.
