**Periodic and singular Sturm**

Liouville Problems Analogous to matrix Eigen value problem which is a minus lambda  $i$  into  $x$  equal to zero so we have defined regular Sturm Liouville system for a differential equation ok, so you have given a differential equation so you will have an operator  $L$  ok you can put it in some nice form a derivative so with some reduction so we have defined kind of normal form so that is  $L y$  equal to  $\lambda y$ ,  $y$  is the solution.

So for this equation on a finite domain in the interval  $ab$  you have defined have given some boundary conditions so for which you provide these boundary conditions when the  $p$  of  $x$  coefficient of second order term second order derivative if it's non zero at the end points then it is called regular Sturm Liouville system for which you have given the boundary conditions this Eigen value problem  $Ly$  equal to  $\lambda y$ .

With these boundary conditions its regular Sturm Liouville system so so why we defined these boundary conditions in order to make  $L$  is Hermitian ok in order to make the operator  $L$  differential operator  $L$  to be Hermitian or self ad joint or skew symmetric we can also do in a different way when  $p$  of  $a$  equal to zero or  $p$  of  $b$  equal to zero or  $p$  of  $a$  or  $p$  of both of them are zero or when also in other case you can also do make it the operator may can make it Hermitian.

When  $p$  of  $a$  equal to  $p$  of  $b$  ok so these two cases we will see later so before I see them we will try to give the regular Sturm Liouville systems some examples ok we will just do some examples for the regular Sturm Liouville system so this is the regular Sturm Liouville system we have seen so this is a together so if you have given equation like this.

(Refer Slide Time: 02:14)

1. Regular Sturm-Liouville problem:

$$Ly = \lambda y', \quad L = -\frac{1}{w(x)} \left[ \frac{d}{dx} \left( P(x) \frac{d}{dx} \right) + q(x) \right]$$

where  $P(a) \neq 0, P(b) \neq 0$ . Assume that  
 $P(x) > 0, x \in (a, b), q(x), w(x) > 0$

Boundary conditions

$$\begin{cases} \alpha_1 y(a) + \alpha_2 y'(a) = 0 \\ \beta_1 y(b) + \beta_2 y'(b) = 0 \end{cases}$$

Not both  $\alpha_i$ 's or  $\beta_i$ 's are zero  
 $\alpha_i$ 's,  $\beta_i$ 's are real

System

$$\begin{cases} Ly = \lambda y', & x \in (a, b), & P(a) = P(b) \neq 0 \\ \alpha_1 y(a) + \alpha_2 y'(a) = 0 \\ \beta_1 y(b) + \beta_2 y'(b) = 0 \end{cases}$$

And you have these boundary conditions like this. So you can find the Eigen values and Eigen functions like I explained in the steps, steps to do find the Eigen values and Eigen vectors and once you see this if you see the all the Eigen values are distinct then corresponding Eigen functions are orthogonal with respect to the dot product that is defined based on your operator L.

(Refer Slide Time: 02:42)

Steps:

1. Find the eigenvalues and eigenfunctions ✓
2. eigenfunctions corresponding to distinct eigenvalues are orthogonal w.r. to the dot product. 
3. eigenfunctions form a complete orthogonal set

Any function  $f(x) = \sum_{n=1}^{\infty} c_n u_n(x)$  (Fourier series)

$$\langle f(x), v_n \rangle = \sum_{m=1}^{\infty} c_m \langle u_m, v_n \rangle$$

$$= c_n \langle u_n, v_n \rangle$$

$$\Rightarrow c_n = \frac{\langle f(x), v_n \rangle}{\langle u_n, v_n \rangle} \checkmark$$

Orthogonality condition:  $\langle u_1, u_2 \rangle = 0$

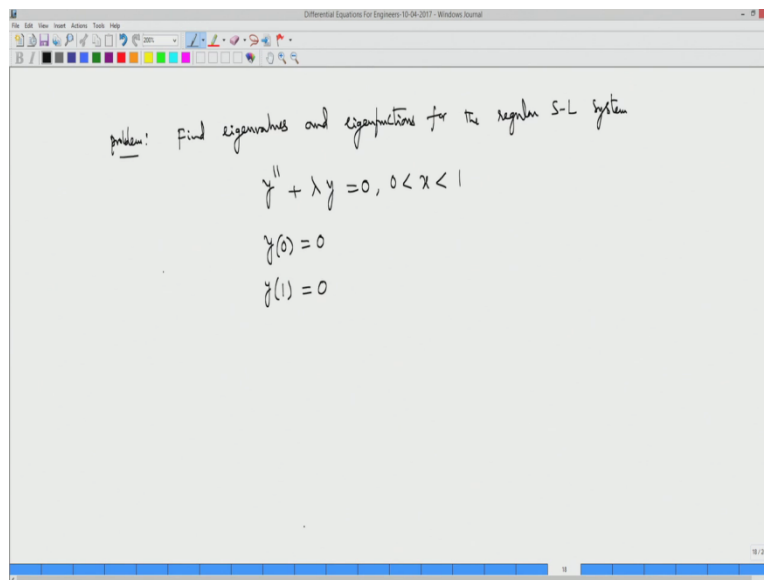

$$\langle \sum_{n=1}^{\infty} c_n u_n, u_2 \rangle = 0$$

$$\Rightarrow c = -\frac{\langle u_1, u_2 \rangle}{\langle u_2, u_2 \rangle}$$

And once you have this once you get all these Eigen functions they form orthogonal which you know and they are complete.

That means any function  $f(x)$  can write in terms of this any actually square Integrable function you can write in terms of these Eigen functions ok so that is actually a Fourier series and then how do you these are arbitrary constants  $c_n$ 's are arbitrary constants those things you can find just by using the dot product so make a dot product both sides with  $b_n$  and so that you can get your  $c_n$  ((03:14).

(Refer Slide Time: 03:21)

So we will see some examples how we do this . So what we do is of make a problem like problem find Eigen values and Eigen functions for the regular SI system that is  $y'' + \lambda y = 0$   $\lambda$  is a parameter and your domain is between zero to one and the boundary conditions are given as  $y(0) = 0$   $y(1) = 0$  so these are your boundary conditions so this is your system.

(Refer Slide Time: 04:10)

Soln:  $\frac{d}{dx} \left( \left( \frac{dy}{dx} \right) + 0 \cdot y + \lambda \cdot y \right) = 0, \quad 0 < x < 1$

$p(x)=1, \quad q(x)=0, \quad w(x)=1 \quad \langle f, g \rangle := \int_0^1 f(x)g(x) dx$

Since  $L$  is self-adjoint or Hermitian,  $\lambda$  is always real.

Possible values: (i)  $\lambda > 0$ , (ii)  $\lambda = 0$ , (iii)  $\lambda < 0$

$\lambda = \mu^2, \mu > 0 \quad \lambda = -\mu^2, \mu > 0$

(1)  $\frac{d^2y}{dx^2} + \mu^2 y = 0$

So how do I solve this I need to find Eigen values and Eigen functions so first we want to see put it as equation where lambda is a parameter this you put it as Eigen value problem, what is Eigen value problem? So you know so if for a matrix  $Ax = \lambda x$  or  $Ax = \lambda I x$  this is your Eigen value problem so try to look for  $x$  for each lambda values ok fix your lambda or find those values of lambda for which you have a non zero solution  $x$  those are your Eigen values and Eigen vectors so you do the same thing.

So try to put this equation in this form first that I can write like earlier so this is like  $My = 0$  ok  $M$  like  $M$  equal to zero  $M$  is the operator so  $M$  is actually same as  $L$  you can see that ok so the second order differential equation I will put it in a nice form so the form which looks like a self adjoint so that is  $y'' + p(x)y' + q(x)y = 0$  so this is like  $\frac{d}{dx} \left( \frac{dy}{dx} + p(x)y \right) + q(x)y = 0$  that is why we are putting so plus  $q$  is zero ok.

Zero into  $y$  plus lambda into one into  $y$  equal to zero ok so from this you can recognize what is your  $p$  of  $x$ ,  $p$  of  $x$  is one,  $q$  of  $x$  is zero and  $w$  of  $x$  is one, moment you see  $w(x) = 1$  immediately you can define the dot product is dot product of any functions is simple zero to one that is your domain  $\int_0^1 f(x)g(x) dx$  it is one ok so  $\int_0^1 f(x)g(x) dx$  so this is your dot product then is actually is easy to find the and you see that this you know that with these boundary conditions.

You have seen that this regular Sturm Liouville system is self ad joint so we know that since it is regular Sturm Liouville system  $L$  is self ad joint or Hermitian we have seen yesterday ok these kind of things are actually Hermitian since this is this  $\lambda$  is always real that is the property of self ad joint or symmetric or skew symmetric matrices values of the Eigen values are real so that is what we are analog ally seeing this here.

Even here it is true but we are not proving it ok so you have this  $\lambda$  is always real so if  $\lambda$  is real we can think of three cases  $\lambda$  is positive,  $\lambda$  equal to zero or  $\lambda$  is negative so these are the three cases you have possibilities ok so real these are the possibilities if  $\lambda$  is positive I can write this as  $\mu^2$  ok with  $\mu$  is positive,  $\lambda$  is this is anyway  $\lambda$  is zero as the same ok.

And here also you can make it like  $\lambda$  equal to minus  $\mu^2$  if  $\mu$  is positive so this is how you make three possibilities and now take the equations so that is actually  $d^2 y$  by  $dx^2$  so look at the case 1 so this is a case 1 this is case 2 and this is case 3 so look at the case 1 where is you take the equation  $d^2 y$  by  $dx^2$   $q$  zero plus  $\lambda$  is now  $\mu^2$   $y$  equal to zero.

(Refer Slide Time: 08:24)

possibilities: (i)  $\lambda > 0$ , (ii)  $\lambda = 0$ , (iii)  $\lambda < 0$

" " " "

$\lambda = \mu^2, \mu > 0$ ,  $\lambda = -\mu^2, \mu > 0$ .

(i)  $\frac{d^2 y}{dx^2} + \mu^2 y = 0$   $L\mu$

$y(x) = e^{kx}$ ,  $k^2 + \mu^2 = 0$ ,  $k = \pm i\mu$

general soln is  $y(x) = C_1 \cos \mu x + C_2 \sin \mu x$

$\checkmark y(0) = 0 \Rightarrow C_1 + 0 = 0 \Rightarrow C_1 = 0$

---

$y(x) = C_2 \sin \mu x$

$y(1) = 0 \Rightarrow C_2 \sin \mu = 0$

So this is a second order equation with constant coefficients. I know it's solution by earlier methods you look for  $y(x)$  as  $e^{kx}$  ok  $y$  of  $x$  you look for  $e^{kx}$  what you get is you get

$k$  square plus  $\mu$  square equal to zero so that gives me  $k$  equal to minus  $\mu$  square so that is plus or minus  $i\mu$  ok so your solution is general solution is  $y$  of  $x$  equal to some  $c_1 e^{\mu x}$  plus  $c_2 e^{-\mu x}$  or  $c_1 c_2$  are arbitrary constants or you can also write  $c_1$  there is no real part.

So  $\cos \mu x$  plus  $\sin \mu x$  or two linearly independent solutions so you can write  $\cos \mu x$  plus  $c_2 \sin \mu x$  ok so in this case I want so we have not applied the boundary conditions so far so what are the boundary conditions?  $y$  zero is zero so you apply  $y$  zero equal to zero implies  $c_1 \cos \mu$  zero that is one plus  $c_2$  zero  $c_2$  into zero into 1 ok this is one plus  $c_2$  into  $\sin \mu$  zero, zero equal to zero so this will give me  $c_1$  equal to zero.

So if I apply these boundary condition now my general solution becomes  $y$  equal to  $c_2 \sin \mu x$  ok, now you apply the other boundary condition so  $y$  at 1 equal to zero so if you apply this for this now you have  $c_2 \sin \mu$  equal to zero now  $c_2$  is if you take  $c_2$  zero then what happens you get a zero solution you are interested to find non zero solution for a Eigen value problem so here also when you write like this  $ly$  equal to  $\lambda y$  ok.

So if you want for every  $\lambda$  whatever  $\lambda$  you take which here in this case I have taken minus  $\mu$  square so that is plus  $\mu$  square so I am looking for non zero solution  $y$  ok?

(Refer Slide Time: 10:54)

The image shows a whiteboard with handwritten mathematical work. At the top, it says  $y(0) = 0 \Rightarrow c_1 + c_2 = 0 \Rightarrow c_1 = -c_2$ . Below that, the general solution is given as  $y(x) = c_2 \sin \mu x$ . Applying the boundary condition  $y(1) = 0$  leads to  $c_2 \sin \mu = 0$ . The case  $c_2 = 0$  is crossed out, leaving  $\sin \mu = 0$ . This leads to  $\mu = n\pi$ , where  $n = 1, 2, 3, \dots$ . The resulting eigenfunctions are  $y_n(x) = \sin n\pi x$  for  $n = 1, 2, 3, \dots$ , which are marked as "eigenfunctions". The corresponding eigenvalues are  $\lambda = -\mu^2 = -n^2\pi^2$ , which are marked as "eigenvalues".

So if I want non zero solution  $c_2$  has to be non zero ok so if I take  $c_2$  zero I get only zero solution so that means actually I have only zero solution so but I am looking for non zero solution so do I have values of  $\mu$  for which I get  $c_2$  non zero ok.

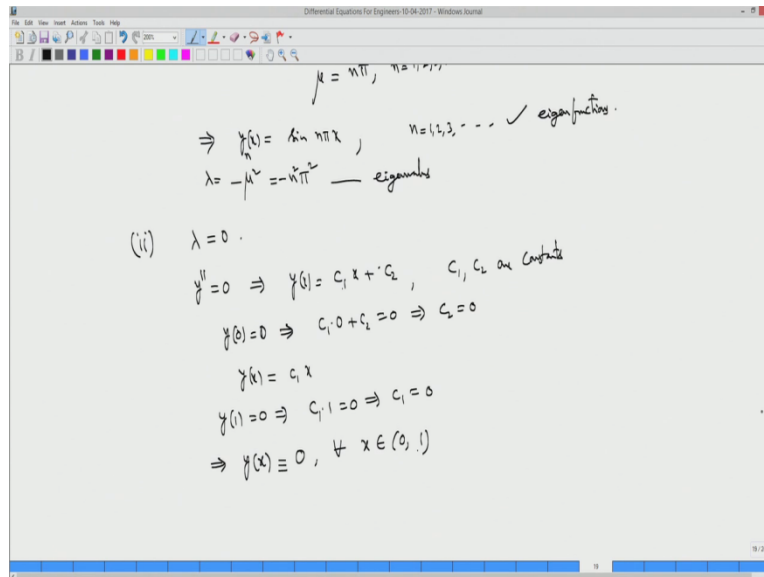

Still this quantity is zero so you have write  $\sin \mu$  is zero for certain  $\mu$  values if no  $\mu$  values satisfying  $\sin \mu$  equal to zero that means  $c_2$  is zero is the only option that means you don't have any non zero solution implies that is that corresponding  $\mu$  all those  $\mu$  values you considered ok are not Eigen values but here you have  $c_2$  is zero or  $\sin \mu$  equal to zero but this case we don't take it because if you take  $c_2$  equal to zero what you get is simply zero solution.

Which is not desirable ok so this will give me other option is  $n\pi$   $\mu$  is remember  $\mu$  is always positive strictly positive so  $n\pi$   $n$  is from 1, 2, 3 and so on ok because  $\mu$  is always positive so this implies what is your solution  $y(x)$  equal to  $c_2$  you can choose  $c_2 \sin \mu x$  is a solution of this homogeneous equation so any constant multiple is also solution you can take this arbitrary constant as 1 so you have a non zero solution is now replace  $c_2$  take it as 1 for each  $\mu$ .

For each  $n$  ok,  $n$  is from 1, 2, 3 onwards what you consider is  $c_2$  is 1 so  $\sin n\pi x$  so these are your solutions ok what is your  $\mu$ ,  $\mu$  equal to  $n\pi$  for each if when  $\mu$  is  $n\pi$  I have this solution what is  $\mu^2$   $\mu$  is when  $\mu$  is  $n\pi$  what is actually  $\lambda$ ?  $\lambda$  is minus  $\mu^2$  ok so that is minus  $\mu^2$  that is  $\lambda$  so that I have minus  $\mu^2$  is actually  $n^2 \pi^2$  ok.

So these are your Eigen values corresponding to this that is  $\mu$  equal to  $n\pi$  I have corresponding solution  $y_n$  you can call this  $y_n$  because it depends on  $n$  ok so these are Eigen functions ok so what you know so what you have seen is you just found only Eigen values and Eigen functions for this regular Sturm Liouville system ok so what else you can do now we can also say that these Eigen functions no you have not found so far. So far these are the Eigen values and Eigen functions.

(Refer Slide Time: 14:04)

$\mu = n\pi, n = 1, 2, 3, \dots$

$\Rightarrow y_n(x) = \sin n\pi x, \quad n = 1, 2, 3, \dots$  ✓ eigenfunctions.

$\lambda = -\mu^2 = -(n\pi)^2$  — eigenvalues

(ii)  $\lambda = 0$ .

$y'' = 0 \Rightarrow y(x) = c_1 x + c_2, \quad c_1, c_2$  are constants

$y(0) = 0 \Rightarrow c_1 \cdot 0 + c_2 = 0 \Rightarrow c_2 = 0$

$y(x) = c_1 x$

$y(1) = 0 \Rightarrow c_1 \cdot 1 = 0 \Rightarrow c_1 = 0$

$\Rightarrow y(x) \equiv 0, \quad \forall x \in (0, 1)$

You still have to see two more possibilities that is lambda equal to zero and lambda is less than zero so you look at the case two, you quote some Eigen values and Eigen functions now look at the case two that is lambda equal to zero in this case what happens to your equation  $y''$  equal to zero so what is a general solution here? Is simply  $c_1x$  plus  $c_2$  so you simply integrate you will get this arbitrary  $c_1$   $c_2$  are.

Arbitrary constants so now we apply  $y$  zero equal to one,  $y$  zero is zero will give me  $c_1$  into zero plus  $c_2$  equal to zero that is nothing but  $c_2$  is zero now what happens to your general solution now, simply  $c_1x$  now you apply  $y$  at 1 equal to zero for this you get that is  $c_1$  into 1 equal to zero that is  $c_1$  is zero, so this implies what is your  $yx$  now what you got  $yx$  is simply  $c_1$   $c_2$  both are zero so this is zero identically zero for every  $x$  in zero 1 ok.

(Refer Slide Time: 15:20)

$\lambda = 0$  is not an Eigenvalue.

(iii)  $\lambda < 0$ ,  $\lambda = -\mu^2$ ,  $\mu > 0$

$$y'' - \mu^2 y = 0$$

$$y(x) = e^{kx}, \quad k^2 - \mu^2 = 0, \quad k = \pm \mu$$

general soln  $y(x) = c_1 e^{\mu x} + c_2 e^{-\mu x}$

$$y(0) = 0 \Rightarrow c_1 + c_2 = 0 \Rightarrow c_1 = -c_2$$

$$\Rightarrow y(x) = c_1 [e^{\mu x} - e^{-\mu x}] = 2c_1 \sinh(\mu x) \checkmark$$

$$y(1) = 0 \Rightarrow 2c_1 \cdot 0 = 0$$

So that means lambda equal to zero is not an Eigen value ok so you don't have Eigen values, you don't have Eigen functions corresponding to lambda equal to zero because you don't have non zero solution there, now look at the third case lambda is negative so that means lambda is minus mu square mu is positive so in this case y double dash what is your lambda y lambda is minus right so lambda is minus mu square so you have minus mu square y equal to zero.

So what is the general solution here you write again you look for y e power kx kind of solutions you get k square minus mu square equal to zero that gives me plus or minus mu, mu is positive ok so you have a general solution is yx equal to c1 e power mux plus c2 e power minus mux now again you apply these boundary conditions whatever you have y zero is zero will give me c1 plus c2 equal to zero ok, so if this will give me c1 equal to minus c2 so the general solution becomes.

C1 is minus c2 so you have c1 c2 I replace with minus c2 c2, c1 c1 c2 you replace with minus c1 so what you get is e power mux minus ok so this is equal to c1 by 2 and another two times c1 into this is sin hyperbolic mux that is your general solution, now you apply other boundary condition y at 1 is zero will give me now y at zero will give me 2c1 sin hyperbolic zero that is zero right this is zero into zero is zero right so c1 is arbitrary constant y at 1 right.

(Refer Slide Time: 17:46)

$$\text{general solution } y(x) = c_1 e^x + c_2 e^{-x}$$

$$y(0) = 0 \Rightarrow c_1 + c_2 = 0 \Rightarrow c_1 = -c_2$$

$$\Rightarrow y(x) = c_1 [e^x - e^{-x}] = 2c_1 \sinh(x) \checkmark$$

$$y(1) = 0 \Rightarrow 2c_1 \sinh(1) = 0$$

$$\sinh(\mu) = 0 \Rightarrow \text{no } \mu > 0 \text{ satisfies } \sinh(\mu) = 0$$

$$\Rightarrow c_1 = 0$$

$$\Rightarrow y(x) \equiv 0, \quad \forall x \in (0, 1)$$

$$\lambda = -\mu^2, \quad \mu > 0 \text{ is not an eigenvalue.}$$

Y at 1 sorry this is y at 1 so it should be sin hyperbolic mu equal to zero so again either c1 is zero if c1 is zero you don't want because you want to see whether any because if c1 is zero then both c1 and c2 are zero that implies you have zero solution that means that you don't want you will just looking for non zero solution whether any possible mu you have a non zero solution ok so you have to see sin mu hyperbolic mu equal to zero.

This will give me what are the values for which mu is and I know that mu is positive ok so there is no solution no mu positive satisfies sin mu hyperbolic mu equal to zero that implies what? So you don't have any mu, mu positive satisfying this one because lambda equal to minus mu square mu is strictly positive so there is no so this cannot be zero so that implies c1 has to be zero that implies a general solution becomes completely zero for every x in zero implies lambda equal to minus mu square for mu positive is not an Eigen value.

(Refer Slide Time: 19:26)

$\Rightarrow y(x) \equiv 0, \forall x \in (0, 1)$   
 $\lambda = -k^2, k > 0$  is not an eigenvalue.  
 $\Rightarrow \lambda_n = -n^2 \pi^2$  are eigenvalues  
 $v_n(x) = \sin n \pi x$  are eigenfunctions  $n = 1, 2, 3, \dots$   
 $\langle v_n, v_m \rangle = \int_0^1 \sin n \pi x \sin m \pi x dx = 0, m \neq n$   
 $\langle v_n, v_n \rangle = \int_0^1 \sin^2 n \pi x dx = \int_0^1 \frac{1 - \cos 2n \pi x}{2} dx = \frac{1}{2}$

So what you have seen in three cases lambda negative is not an Eigen value lambda equal to zero is not an Eigen value only here you get Eigen values ok, lambda so case 1 that is for lambda positive you have an Eigen value lambda equal to mu square or Eigen values so you found what are the Eigen values and Eigen functions minus n square pi square and sin and pi x.

Or the Eigen values and Eigen vectors Eigen functions respectively so the answer is solution finally minus n square pi square or Eigen values and then sin n pi x or Eigen functions corresponding to n is from 1, 2, 3 and so on because n equal to zero is not an Eigen value and n equal to zero you see that this becomes zero so these are your Eigen values and Eigen functions so you found only first step and so what is the second step?

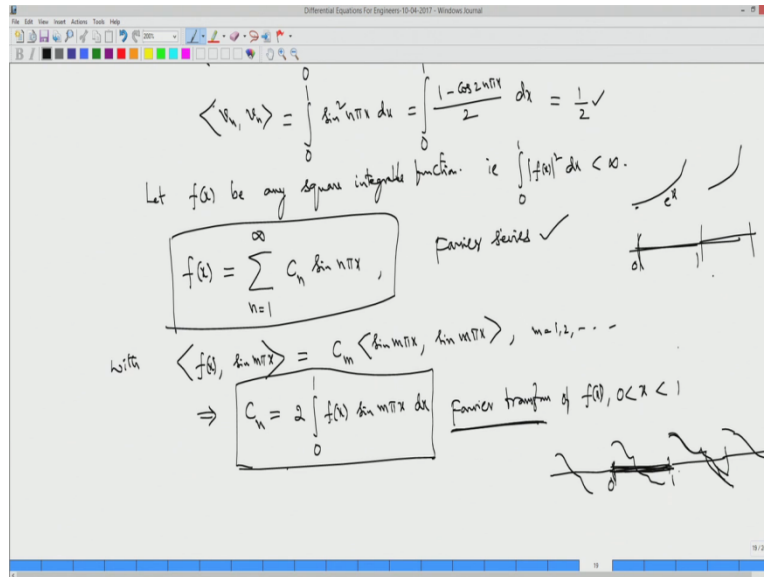

So we can see that these Eigen functions you can actually verify ok so you can actually verify these Eigen functions if you call them as  $v_n$  of  $x$  and these are your lambda n's corresponding to lambda n is from 1 to infinity this  $v_n$  and  $v_m$  dot product which we have which we define based on what is your differential operator zero to one sin n pi x sin n pi x dx ok so actually true this is this should be zero whenever m is not equal to n.

So you can easily verify that these actually zero when m is not equal to n but when n equal to m that is  $v_n \cdot v_n$  ok sin square n pi x dx this is one by two ok so this is one minus one minus cos 2n pi x divided by two this is zero to one right so this is what is integration so dx ok so

this is simply because this is  $\sin 2n\pi x$  will get that is between zero to one is zero so only this will contribute one by two this will get simply one by two is the answer.

So you see that these are these functions are Eigen functions they are orthogonal you can easily see and the dot product when they are take the same function so this value is half.

(Refer Slide Time: 22:20)

So what is the third step which we have seen we have told ok so that any function you take any let  $f(x)$  be any square integrable function that is integral zero to one that is your domain modulus of  $f(x)$  whole square  $dx$  is finite so any such function any  $f$  satisfying this ok.

I can write this is what you have to take that is the meaning of complete orthogonal Eigen functions means any function  $f$  square integrable function  $f$  I can write it as a linear combination of all these Eigen functions so what is the linear combination you have infinitely many Eigen functions so linear combination is the sum with some arbitrary constants  $c_n \sin n\pi x$   $n$  id from you have from one to infinity so this is what is the meaning.

So  $f(x)$  I can write like this ok so where  $c_n$  how do I find my  $c_n$  if I can write like this but I still don't know what is my  $c_n$  so  $c_n$  if you apply the dot product both sides  $f(x)$  with  $c_n$  will be dot product with  $v_n$  that is  $\sin n\pi x$  ok so you can say with some  $v_m$  of  $x$  equal to you have  $c_m$   $n$  is only when  $n$  equal to  $m$  with little contribute that is actually  $\sin m\pi x$  and you are multiplying  $v_m \sin m\pi x$  so here also you can put it as  $\sin m\pi x$  ok.

So this will give me this is true for every  $m$  is form one to infinity this is true so this means  $c_m$  or  $c_n$  now you can change  $m$  as  $n$  both are same so  $c_n$  this value we have seen here so there is one by two ok so it means two times integral zero to one now this you can write  $f(x) \sin m \pi x dx$  so this is exactly your fourier transform ok and this is your fourier series, fourier transform of  $f(x)$  is between zero to one any periodic function you can say  $f(x)$  is defined between zero to one.

And let us say you take any function like this signal is given between time zero to one like this and one to two is also its repeated same thing same profile is repeated like that you can go on so its periodically it's the such a signal you can also use you are given this between zero to one you can define you can get this discrete frequencies these are the frequencies this is I will give you the fourier transform and use once you know the all these discrete frequencies.

The time signal you break it into discrete frequencies and finally you can get back your signal itself in terms of this discrete frequencies these frequencies  $c_n$  this number into with these Eigen functions will form will give you as this a fourier series ok is actually fourier series will give you inverse fourier transform of this it's a fourier series here inversion of so you are given a time signal here you break this signal into discrete frequencies.

That is giving fourier transform is giving that if you want (if it's a) suppose you are given all these  $c_n$ 's you want to get back your signal so that is given by this fourier series ok so that is what is you are seeing here so as a regular Sturm Liouville system here you find the Eigen values and Eigen functions and you see that they are actually they form complete orthogonal functions now immediately that means any function.

I can write as  $a$  in terms of them linear combination of these Eigen functions that is actually fourier series so if I ask you to find here find the fourier series of given a function say  $e^{ax}$  you can take  $e^{ax}$  as  $f(x)$  you can write  $f(x)$  in terms of all these Eigen functions  $\sin$  and  $\pi x$  what is actually that, that is actually fourier series for  $e^{ax}$ ,  $e^{ax}$  is given between zero to one as a signal which is periodically repeated.

If you want it is not actually  $e^{ax}$  everywhere  $e^{ax}$  between zero to one only given so one to two is also repeated same  $e^{ax}$  one to two so whatever profile you have between zero to one  $e^{ax}$ ,  $e^{ax}$  zero is one,  $e^{ax}$  one is like this ok so something like this it

will be right so same piece it will be repeated at every one two like that, (such a signal) such a function if you want you can write .

So such a function between zero to one which is e power x you can write in terms of cn sin and pi x where cn's are e power x into sin and pi x dx so because this is n so it should be n ok this is from n is from one to three and so on ok.

(Refer Slide Time: 28:18)

The slide shows the following mathematical content:

$$\frac{d}{dx} \left( p(x) \frac{dy}{dx} \right) + q(x)y + \lambda w(x)y = 0, \quad x \in (a, b)$$

$$Ly = \lambda y, \quad L = -\frac{1}{w(x)} \left[ \frac{d}{dx} \left( p(x) \frac{d}{dx} \right) + q(x) \right]$$

$$\langle Lf, g \rangle = \left[ p(x) \left[ f \frac{dg}{dx} - g \frac{df}{dx} \right] \right]_a^b + \langle f, Lg \rangle, \quad \langle f, g \rangle = \int_a^b w(x) f(x) g(x) dx$$

So this is how you solve or you say you can have given if you see the differential equation if you know the differential operator  $L$  ok? If you are given a second order linear differential equation you can put it in this form get the  $L$  based on that you define your dot product and then make get the Eigen values and Eigen functions you can make a Fourier series ok so this Fourier series whatever you have see the Eigen values and Eigen functions so we will use it to solve partial differential equations ok in the future (so let's get back to) so we will do some more examples like regular Sturm Liouville systems.

So now let us go back to general case second case when what we had is if you are given a differential equation like this any second order differential equation you are putting it now  $px$   $dy$  by  $dx$  into  $ddx$  ok plus  $qx$  into  $y$  plus  $\lambda$  into  $wx$   $y$  equal to zero  $x$  belongs to  $ab$  ok so this is actually your  $ly$  this is  $ly$  plus  $\lambda y$  so  $ly$  equal to minus  $\lambda y$  so actually put it in this form where  $L$  is minus one by  $\omega$   $x$  and this one  $ddx$  of  $px$   $ddx$  plus  $qx$ .

So this is what we have seen  $x$  is between zero to one  $x$  is between  $a$  to  $b$  so for this you have shown that if you have shown that any two functions  $f$  and  $g$  you have  $\int_a^b f g$  equal to you have that special thing that  $\int_a^b p x$  times  $dx$  so what you have that you have seen earlier I can write without saying so this  $\int_a^b p x$  times  $dx$  let me see exactly take exactly what we got  $f$  into  $\int_a^b f g$  bar dash  $\int_a^b f g$  bar dash that is  $\int_a^b p g$  bar by  $dx$  minus  $\int_a^b p f$  bar by  $dx$ .

And this form this whole thing you take this whole thing you take the limit from  $a$  to  $b$  plus and here we get  $\int_a^b p g$  so this is what you have seen only from this ok and the dot product is dot product between  $f$  and  $g$  this means here this is actually from  $a$  to  $b$   $w x$  that is a weight function whenever you have this  $w$  you have to use that, that is positive  $f x g x$  bar  $dx$  this is what is a dot product which you use here this is what you have seen so  $y$  one to make this special thing to zero, if I give certain boundary conditions ok?

(Refer Slide Time: 31:59)

The image shows a digital whiteboard with the following content:

$$\langle Lf, g \rangle = \left[ p(x) \left[ f \frac{dg}{dx} - \bar{g} \frac{df}{dx} \right] \right]_a^b + \langle f, Lg \rangle,$$

periodic S-L system:  $Ly = \lambda y$ ,  $a < x < b$

If  $p(a) = p(b) \neq 0$ ;

B.c's  $y(a) = y(b)$  ✓  
 $y'(a) = y'(b)$  ✓

$$\begin{aligned} p(b) [f(b) \bar{g}'(b) - \bar{g}(b) f'(b)] - p(a) [f(a) \bar{g}'(a) - \bar{g}(a) f'(a)] \\ = p(a) [f(a) \bar{g}'(a) - \bar{g}(a) f'(a)] - p(a) [f(a) \bar{g}'(a) - \bar{g}(a) f'(a)] \\ = 0 \end{aligned}$$

So let us see in this second case ok second that is called a periodic system, periodic Sturm Liouville system so I define this as  $ly$  equal to  $\lambda y$  ok so  $x$  is between  $a$  to  $b$  now I give certain boundary conditions based on if  $p$  of  $a$  equal to  $p$  of  $b$  then what should be the boundary conditions ok it is not regular it is something  $p$  of  $a$  equal to  $p$  of  $b$  but they are not zero and which are not zero.

So that is what is the case in this case I give the boundary conditions are like this boundary conditions are periodic system you get  $y$  at  $a$  equal to  $y$  at  $b$  you expect the solutions also periodic so it's like  $p$  is periodic you expect your solutions are also periodic ok and then  $y'$  at  $a$  is also same as  $y'$  at  $b$  like this you can give your boundary conditions ok these are the boundary conditions.

So if you give this boundary conditions this and this together with this you can make this term so now you can see  $p(b)$  and  $f'(b) - g'(b)$  all are at  $b$  ok so this is one minus now you apply the limit at  $x$  equal to  $a$  that's why we have a minus, minus  $p$  at  $a$   $f'(a) - g'(a)$  so this is what you get that special term becomes this, this value you can easily see now we put  $p(a)$  equal to  $p(b)$ .

So  $p(a)$  is common now what you have  $f(b)$ ,  $f(b)$  is also same as  $p(b)$  right  $f(b)$  equal to  $p(a)$  if you apply this boundary conditions let  $f$  the solution of this system,  $f$  and  $g$  are two solutions of this system ok this equation with this boundary conditions then you have first boundary condition will give me I can replace  $f(b)$  with  $p(a)$  similarly  $g(b)$  is also another solution so is  $g(b)$  is another solution  $g'(a) - g'(b)$  is same as  $g'(b) - g'(a)$ .

So you apply the second here so you get  $g'(a)$  similarly here so because  $g$  now for  $g(b)$  is a solution and you apply the first condition you get  $g'(a)$  and similarly for  $f$   $f$  is a solution of this system you apply the second condition for  $f$ ,  $f'(a)$  and this is same as a second one so this is repeated  $p$  of  $a$  this you write as it is so both are same so this is actually equal to zero, ok?

(Refer Slide Time: 35:30)

$$\frac{d}{dx} \left( p(x) \frac{dy}{dx} \right) + q(x)y + \lambda w(x)y = 0, \quad x \in (a, b)$$

$$Ly = \lambda y, \quad L = -\frac{1}{w(x)} \left[ \frac{d}{dx} \left( p(x) \frac{d}{dx} \right) + q(x) \right]$$

$$\langle f, g \rangle = \int_a^b w(x) f(x) g(x) dx$$

$$\langle Lf, g \rangle = \left[ p(x) \left( f \frac{dg}{dx} - \bar{g} \frac{df}{dx} \right) \right]_a^b + \langle f, Lg \rangle$$

(2) periodic S-L system:  $Ly = \lambda y, \quad a < x < b$   
 If  $p(a) = p(b) \neq 0$ ;  
 B.C's  $\begin{cases} y(a) = y(b) \\ y'(a) = y'(b) \end{cases}$   

$$p(b) [f(a) \bar{g}'(b) - \bar{g}'(a) f(b)] - p(a) [f(a) \bar{g}'(a) - \bar{g}'(a) f'(a)]$$

$0 \cdot \infty = \text{indeterminate}$

So that means you made this this term zero. Again if I provide these boundary conditions so this is periodic Sturm Liouville system so if you can give to your differential equation this Eigen value problem with these boundary conditions that also make this operator self adjoint or skew symmetric ok so this is another case this is case two so this is periodic system so what else in what are the other forms you can so what is left is now if p of a is zero or p of b is zero.

Or both are zero in that case what boundary conditions you have to give to make this special terms this boundary term zero ok we will see that, that is singular Sturm Liouville system so what is actually p, p is actually here so p if p is zero that is a coefficient of second order derivative highest derivative if p is zero p at a is zero that means a is a singular point right if is singular point so b is also singular point if p of b is zero.

Both are zero ab are similar point like you have seen for legendary equation ok legendary equation is defined one minus x square y dash right y double dash so you can see that p of x is one minus x square there you see that zero minus one and plus one both are zero they are is like that so that is an example you can see that both there is a possibility for certain equations for both p of a p of b both are zero so in such a case.

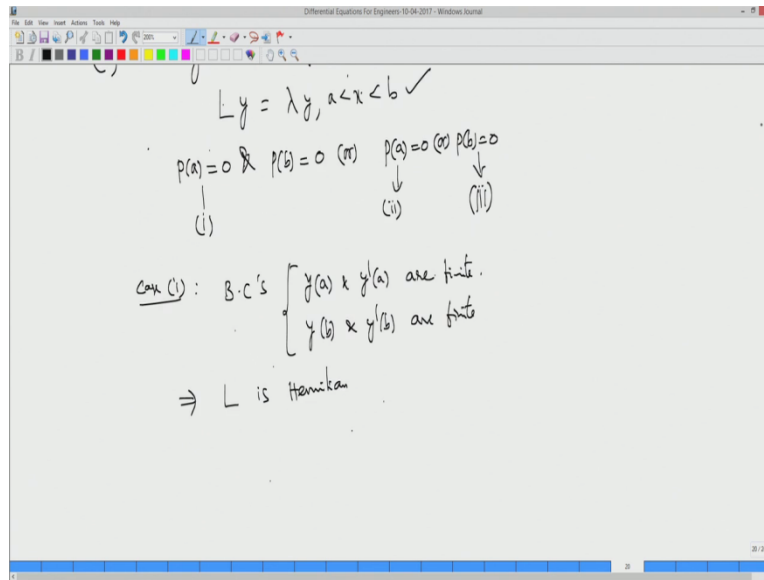

So you see that  $p$  of  $a$  is zero  $p$  of  $b$  is zero or one of them is zero and this quantity when can you say that zero into something you want to zero is it zero, zero into something is zero this something if you want this to be zero this something has to be finite ok because zero into infinity you cannot say is indefinite ok indefinite this can be anything ok this can be even for some non zero quantity so you have to make sure that this quantity is finite ok.

So how can make sure so that is that you are giving through your boundary conditions if  $p$  of  $a$  is zero ok then you make sure that this quantity at  $a$  is also zero that means  $f$  or any solution  $f$  and its derivative this one or  $g$  its derivative has to be bound at  $a$  that is a condition right  $f$  and  $g$  bar are solutions  $f$  and  $f$  dash or  $g$  and  $g$  bar,  $g$  bar and its  $g$  bar dash they are the solutions right  $g$  and  $g$  bar if they are boundary.

If you say that a solution and its derivative is bounded at  $x$  equal to  $a$  that make sure that this quantity is finite ok so the finite into  $p$  at  $a$  is zero that is known so zero into finite quantity is zero that makes this term is zero at  $x$  equal to  $a$  if  $p$  at  $b$  is also zero ok then you have zero here and you can make this zero ok so this again you have to make sure that  $f$  one its derivative a solution and its derivative are also bounded at  $b$ .

Then together it will become zero ok normally you see either both of them are zero so it's rather that one side it is zero and the other side is non zero ok what happens if  $p_b$  is non zero  $p_a$  is zero  $p_b$  is non zero let us say  $p_b$  is non zero you have to make sure that this quantity is zero ok if you want this quantity is zero either you have to give the second boundary condition like because  $p_b$  is non zero ok then either  $f$  is at  $b$  is zero or its derivative at  $b$  is zero one of these you can give you can fix your boundary conditions, ok?

(Refer Slide Time: 39:44)

So we will see this as a singular Sturm Liouville system ok again you have  $ly$  equal to  $\lambda y$   $x$  is between  $a$  to  $b$  and what we will see three different cases here  $p$  of  $a$  equal to  $p$  of  $b$  sorry  $p$  of  $a$  is zero and  $p$  of  $b$  is zero so you have three cases this or  $p$  of  $b$  is zero or both  $p$  of  $a$  equal to zero and  $p$  of  $b$  equal to zero so this is case one this is case two this is case three ok.

So in this case first case ok let's look at that case three as first one ok so if you want this you write it as this and this both are zero this you put it as  $r$  so that this is your case one and this is your case two and this is your case three so let's look at the case one where both  $p$  and  $p_b$  are zero ok case one so you want that special term that is if you look at this so that is this one  $p$  of  $b$  so what are the boundary conditions you give.

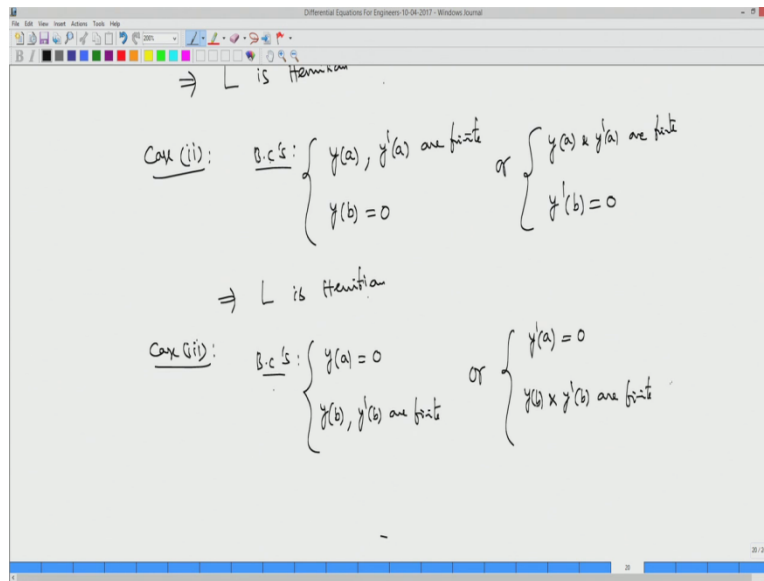

So boundary conditions for case one when  $p$  of  $a$   $p$  of  $b$  is zero or  $y$  and  $y$  at  $a$  and  $y$  at  $b$   $y$  dash at  $a$  are finite ok if  $y$  is finite and  $y$  is defined between  $a$  to  $b$  and at the boundary it is finite its derivative when it exist it is also finite ok so that is how you can say that both will be together so will be true if  $y_a$  is finite ok and other boundary condition is  $y_b$  and  $y$  dash  $b$  are finite so these are your boundary conditions if with these boundary conditions.

This equation you can make this quantity because now this  $p_a$   $p_b$  both are zero, zero into your make because of this boundary conditions  $y$  and  $p$  ( $f$  and  $g$  are)  $f$  and  $g$  bar are satisfying these two boundary conditions that make this quantity and this quantity finite so zero into finite zero

minus zero into finite finally zero so you see that again that special term here is a boundary term is zero so what you have seen is lfg equal to flg dot product.

So again you see that this is Hermitian so you can see that now once you get here immediately say that l is Hermitian ok in the earlier case now in the singular Sturm Liouville system case also l is Hermitian

(Refer Slide Time: 42:54)

What is a case two? Case two or case three we will see boundary conditions will be because p of a is zero I want to make sure that this quantity is zero so you have to give the same boundary conditions this y at a y at b and y at y dash at a are finite.

That is first boundary condition one ok, a second boundary conditions because p of a is only known ok p of b maybe non zero that means p of b is non zero if p is non zero though I have a non zero so p of b is non zero this quantity so when this will become zero together so this becomes zero this is non zero into if you want to make this zero f at b f g bar at b either this or a derivative value at b has to be zero so your solution you can give two boundary conditions.

Y at b equal to zero ok or same boundary condition for the first one y of a and y dash at a are finite or y dash at b is zero so either of this boundary conditions we will work we will make it make this special term zero ok so that you have lfg that is l will be self adjoints so this again

implies make it self adjoint, case two is simply repetition of case one, case three is simply replace boundary condition simply instead of a you interchange a and b ok.

You simply write for the sake of completeness so you can give this boundary conditions for  $y$  equal to  $\lambda y$ ,  $y$  at  $a$  equal to zero ok and  $y$  at  $b$   $y'$  at  $b$  are finite ok or these boundary conditions  $y$  at  $y'$  at  $a$  equal to zero and  $y$  at  $b$  and  $y'$  at  $b$  are finite.

(Refer Slide Time: 45:10)

The slide shows the following mathematical work:

$$\langle Lf, g \rangle = \left[ p(x) \left[ f \frac{d\bar{g}}{dx} - \bar{g} \frac{df}{dx} \right] \right]_{x=a}^x + \langle f, Lg \rangle,$$

(2) periodic S-L system:  $Ly = \lambda y$ ,  $a < x < b$

If  $p(a) = p(b) \neq 0$ ;

B.c's  $\begin{cases} y(a) = y(b) \\ y'(a) = y'(b) \end{cases}$

$0 = 0$   
 $\downarrow$   
 $b=a$   
 $0 \cdot \infty = \text{indeterminate}$

$$\begin{aligned} & p(b) [f(b) \bar{g}'(b) - \bar{g}'(b) f(b)] - p(a) [f(a) \bar{g}'(a) - \bar{g}'(a) f(a)] \\ &= p(a) [f(a) \bar{g}'(a) - \bar{g}'(a) f(a)] - p(a) [f(a) \bar{g}'(a) - \bar{g}'(a) f(a)] \\ &= 0 \Rightarrow L \text{ is Hermitian} \end{aligned}$$

With these boundary conditions you make this boundary terms will be zero so that makes the differential operator as self adjoint or Hermitian or skew symmetric ok.

So once it is Hermitian so we can just find the Eigen values and Eigen functions ok so the inner product is same sorry dot product is here the dot product is periodic system, what is the dot product here? So whatever once you have the Hermitian (you can) you have seen the dot product is same so that is a to b ok we have written already so the dot product is same so this is what you have always ok it doesn't change here.

So we will see the examples in each of these cases for the periodic Sturm Liouville system and singular Sturm Liouville system in the next video, we will see these two special Sturm Liouville systems periodic Sturm Liouville system and singular Sturm Liouville system so when you are

given a differential equation as a Eigen value problem with one of these boundary conditions so you can see that it will be either regular.

Or periodic or singular Sturm Liouville systems so I have given an example for the regular Sturm Liouville system and in the next video we will have examples for periodic and singular Sturm Liouville systems ok.
