Examples of Regular Sturm-Liouville Systems.

(Refer Slide Time: 0:54)

Welcome back, in the last few videos we have seen one example of regular Sturm-Liouville system to find the eigenvalues and eigen functions and rest examples for periodic and singular Sturm-Liouville systems we have seen. Today we will just have, we will have 2 more examples of different way of finding eigenvalues and eigen functions for the regular Sturm-Liouville system. So to start with the 1st example which I explained in the last video. So we can see this, this is the example, so for which you can find eigenvalues are eigen functions, so little different from the work we have done for the 1st example of regular Sturm-Liouville system.

(Refer Slide Time: 2:10)

$$I.F = e^{-2x}$$

$$e^{-2x} y'' - 2e^{-2x} y' + \lambda e^{-2x} y = 0, \quad 0 < x < \pi$$

$$L y = -e^{2x} \frac{d}{dx} \left(e^{-2x} \frac{dy}{dx} \right) = \lambda y, \quad 0 < x < \pi$$

$$L = -\frac{d}{dx} \left(e^{-2x} \frac{d}{dx} \right), \quad \langle f, g \rangle = \int_0^\pi e^{-2x} f(x) g(x) dx$$

So you need to take the differential equation plus lambda y equal to 0, so this you want to put it in this Sturm-Liouville system, so self-adjoint form or Hermitian form or skew-symmetric form, so whatever you say. So x is between 0 to pi, this is what is the domain. You need to put this together as derivative of something, so to do this, this is just a linear equation of time, right. So if you think of y – is a dependent variable, you have dy – by dx - 2 dy by dx, okay. So that dy – minus 2y –. So for y – is a linear equation, so you know that integrating factor is e power integral p, p is here -2 dx.

So you have e power minus 2x, that is the integrating factor for these 2 terms. So if you multiply this equation e power minus 2x, so e power minus 2x double dash - 2 into e power minus 2x y – plus lambda into e power minus 2x y equal to 0, so that x is between 0 to pi. Now I can put this with multiplication of the integrating factor, we can combine these 2 as derivative of e power minus 2x y – or dy by dx. Okay 1 you can see that e power minus 2x y double dash, and if you differentiate this, you get e power minus 2 into the e power -2 xy –. So plus q0 and you have, you can put this as outside minus and this will be lambda into e power minus 2xy, okay.

So this is actually your Ly, Ly has a definition, so x is between 0 to pi and l is minus ddx. Now p is minus e power minus 2x, okay. And q is 0, so 0 into 0, simply q is 0, so we do not write this. So this is what, so once you identify this operator, we can write the dot product of 2 functions. Here the definition is from this domain which is 0 to pi and w, so w is, you have a w here, so e power minus 2x, so, so you can just divide with this okay, so you can write 1

by e power, so you can write, bring this e power minus 2x this side, that is going to be plus, okay. This is going to be plus, so you can remove this, so where l is 1 over e power minus 2x.

(Refer Slide Time: 4:29)

$$y'' - 2y' + \lambda y = 0, \quad 0 < x < \pi$$

$$I \cdot F = \frac{-2y' - 2x}{e} = e$$

$$e^{-2x} y'' - 2e^{-2x} y' + \lambda e^{-2x} y = 0, \quad 0 < x < \pi$$

$$L y = -e^{2x} \frac{d}{dx} \left(e^{-4x} \frac{dy}{dx} \right) = \lambda y, \quad 0 < x < \pi$$

$$L = -\frac{d}{dx} \left(e^{2x} \frac{d}{dx} \right), \quad \langle f, g \rangle = \int_0^{\pi} e^{-2x} f(x) \overline{g(x)} dx$$

$$\lambda \text{ is real \& } L \text{ is in Hermitian form.}$$

$$y'' - 2y' + \lambda y = 0 \checkmark$$

$$\text{Let } y(x) = e^{kx}, \quad k^2 - 2k + \lambda = 0$$

$$k = \frac{2 \pm \sqrt{4 - 4\lambda}}{2} = 1 \pm \sqrt{1 - \lambda}$$

$$\text{general solution is } y(x) = c_1 e^{(1 + \sqrt{1 - \lambda})x} + c_2 e^{(1 - \sqrt{1 - \lambda})x} \checkmark$$

$$\lambda \in \mathbb{R}$$

So this is your w, so w is this into fx gx bar dx, this is a dot product you have. So this is what is your sturm louisville equation ly equal to lambda as the eigenvalue problem. Okay. So you need to find the eigenvalues and eigen vectors. Now consider, so consider now l is the self adjoint from, so you have hermitian form implied, lambda is real. Lambda is real since l is in hermitian form or skew symmetric form. So we can now consider, so lambda is real means it can be positive, negative and all such thing. You 1st consider the general solution of the equation, given equation.

So that is $y'' - 2y' + \lambda y = 0$. Okay, so this form, what are the solutions, this is the linear equation with constant coefficients, you can look for solutions in this form e^{kx} . If you look for this form, you put it, you get $k^2 - 2k + \lambda = 0$. So that will give me whatever my k values through plus or minus square root of $b^2 - 4ac$ divided by $2a$. So this will give me $1 +$ or $1 -$ square root of $1 - \lambda$. So these are your roots, so implies you have this general solution, general solution is $y(x)$ which is the second-order equation, so you can get the general solution as some c_1 times $e^{(1 + \sqrt{1 - \lambda})x} + c_2 e^{(1 - \sqrt{1 - \lambda})x}$.

(Refer Slide Time: 6:41)

$\lambda \in \mathbb{R}: \lambda = 1: k^2 - 2k + 1 = 0$
 $\Rightarrow (k-1)^2 = 0 \Rightarrow k = 1/1$
 general solution is $y(x) = c_1 e^x + c_2 x e^x$
 $y(0) = 0 \Rightarrow c_1 = 0$
 $\Rightarrow y(x) = c_2 x e^x$

When you see here, this is $c_1 e^{(1 + \sqrt{1 - \lambda})x} + c_2 e^{(1 - \sqrt{1 - \lambda})x}$. So this is your general solution. Now, you know that λ is real, we just start with because, see it involves the general solution involves $1 - \lambda$, so let us consider 1^{st} λ is equal to 1, okay. So you can also think, if it is not there, so you can, you can also look at λ positive, λ negative and λ equal to 0. Because it has $1 - \lambda$ in the solution, you have square root of $1 - \lambda$, that suggests you work with λ equal to 1. So if you put λ equal to 1, that is your general solution, so what happens to your roots.

With λ equal to 1 what you get is $k^2 - 2k + 1 = 0$. So you have $(k - 1)^2 = 0$, that will give me $k = 1$ and 1 . So you have repeated roots, so the general solution is, general solution is e^{kx} , $k = 1$, so you have $e^x + c_2 x e^x$, okay. So this is what you have, now you apply boundary conditions. What you have is starting with the 1^{st} boundary condition, $y(0) = 0$, if you apply here, and so

y_0 is 0, so you have c_1 , so c_1 plus c_2 into 0. So that is 0, so this is 0, so you get c_2 is 0, c_1 will be 0.

(Refer Slide Time: 8:33)

The image shows a digital whiteboard with the following handwritten content:

$$y'' - 2y' + \lambda y = 0$$

Let $y(x) = e^{kx}$, $k^2 - 2k + \lambda = 0$

$$k = \frac{2 \pm \sqrt{4 - 4\lambda}}{2} = 1 \pm \sqrt{1 - \lambda}$$

general solution is $y(x) = c_1 e^{(1 + \sqrt{1 - \lambda})x} + c_2 e^{(1 - \sqrt{1 - \lambda})x}$

$\lambda \in \mathbb{R}$: $\lambda = 1$: $k^2 - 2k + 1 = 0$
 $\Rightarrow (k - 1)^2 = 0 \Rightarrow k = 1, 1$

general solution is $y(x) = c_1 e^x + c_2 x e^x$

$y(0) = 0 \Rightarrow c_1 = 0$
 $\Rightarrow y(x) = c_2 x e^x$

$y(\pi) = 0 \Rightarrow c_2 \pi e^\pi = 0 \Rightarrow c_2 = 0$

$\Rightarrow y(x) \equiv 0$

So this implies the general solution becomes $c_2 x e^x$. Now you can apply other boundary conditions. So apply the boundary, other boundary conditions that is we have y pie equal to 0. So if you apply this, you get c_2 by e^x has to be 0, this is possible only if c_2 , c_2 is 0, right. So you have c_2 is also 0, this is positive, since this is nonzero, so c_2 has to be 0. So general solution finally, that implies general solution or the solution satisfying the boundary condition becomes why x is identically 0. So that means λ is equal to 1 is not an eigenvalue. Okay. So we can look at λ greater than 1 and the λ less than 1.

You have 3 cases that we can look at λ greater than, we look at λ greater than 1, then in that case this is your general solution and this will be i , okay. So when λ is greater than 1, general solution of the equation $y'' = \lambda y$ equal to, so e^x power x is common, so you can look at this e^x power one x , the power one x is common, so you can take this out and you have c_1 and what you get is, when λ is greater than 1, $1 - \lambda$ is negative, so you have $\lambda - 1$ times square root of $\lambda - 1$, λ is greater than 1. So you have $c_1 e^{-\sqrt{\lambda - 1} x}$, so you can rewrite, so you have, that involves $e^{\pm i \sqrt{\lambda - 1} x}$, here you power minus $i \sqrt{\lambda - 1} x$.

(Refer Slide Time: 11:06)

$\lambda > 1$: general solution $y(x) = e^x (c_1 \cos(\sqrt{\lambda-1})x + c_2 \sin(\sqrt{\lambda-1})x)$
 $y(0) = 0 \Rightarrow c_1 = 0$ ✓
 $y(x) = e^x c_2 \sin(\sqrt{\lambda-1})x$
 $y(\pi) = 0 \Rightarrow c_2 e^{\pi} \sin(\sqrt{\lambda-1}\pi) = 0$
 $\sin(\sqrt{\lambda-1}\pi) = 0 \Rightarrow \sqrt{\lambda-1}\pi = n\pi, n = 1, 2, 3, \dots$ ✓
 $\Rightarrow \sqrt{\lambda-1} = n$
 $\Rightarrow \lambda = n^2 + 1, n = 1, 2, 3, \dots$
 eigenvalues $\lambda_n = n^2 + 1$

So that you can write also as a linear combination of cosine and sines. So we will write as $\cos(\sqrt{\lambda-1}x)$ plus $c_2 \sin(\sqrt{\lambda-1}x)$, x is outside, okay. So this is your general solution, now you apply the boundary conditions. $y(0)$ will give me, what happens to 0, e^0 is 1, c_1 , that is $c_1 + c_2$, when you put x equal to 0, that is 0, so this is what you get c_1 , this is $y(0)$, so this is equal to 0. So you get again c_1 is 0, so the $y(x)$ becomes $e^x c_2 \sin(\sqrt{\lambda-1}x)$.

Okay. So now we apply another boundary condition $y(\pi) = 0$, that will give me $e^{\pi} c_2 \sin(\sqrt{\lambda-1}\pi) = 0$. So this is nonzero, this cannot be 0 and this can be 0 for some λ values, for $\lambda > 1$. So we have to see what are these values, okay. So for such λ values, c_2 can be arbitrary. So you can take this $\sin(\sqrt{\lambda-1}\pi) = 0$ will give me $\sqrt{\lambda-1}\pi = n\pi$. And you see that this quantity, λ is greater than 1, so this, this should be running from running from 1, 2, 3, onwards.

Reason is n equal to 0, if I take an equal to 0, that will become 0, that is $\lambda = 1$, which already seen that is not an eigenvalue. If I take n negative, then $\sqrt{\lambda-1}$ is actually, it cannot be negative, so it has to be positive. So this is what you are forced so this n values, positive value, so square root, so square root of this number should be positive. So, right so so we have this. So this implies you have $\sqrt{\lambda-1} = n$, this will give me $\lambda = n^2 + 1$, n is running from 1, 2 onwards. So these are your eigenvalues, $\lambda_n = n^2 + 1$ eigenvalues for which you have nonzero solution.

So you can, you have c_2 can be arbitrary, you can take it as 1, e power x for these lambda values.

(Refer Slide Time: 13:41)

Handwritten notes on a whiteboard:

$$\sin \sqrt{\lambda-1} x = 0 \Rightarrow \sqrt{\lambda-1} x = n\pi, \quad n=1,2,3, \dots$$

$$\Rightarrow \sqrt{\lambda-1} = n$$

$$\Rightarrow \lambda = n^2 + 1, \quad n=1,2,3, \dots$$

eigenvalues $\lambda_n = n^2 + 1$, $n=1,2,3, \dots$

eigenfunctions $\psi_n(x) = e^x \sin nx$, $n=1,2,3, \dots$

Handwritten notes on a whiteboard:

eigenfunctions $\psi_n(x) = e^x \sin nx$, $n=1,2,3, \dots$

$\lambda < 1$: $y(x) = e^x (c_1 e^{\sqrt{1-\lambda} x} + c_2 e^{-\sqrt{1-\lambda} x})$

$y(0) = 0 \Rightarrow c_1 + c_2 = 0 \Rightarrow c_1 = -c_2$

$\Rightarrow y(x) = c_1 e^x [e^{\sqrt{1-\lambda} x} - e^{-\sqrt{1-\lambda} x}]$

If you put it, so eigen functions will be, you call them v_n of x which is e power x , $\sin \sqrt{\lambda-1} x$ is n , so you have $\sin nx$. So for both n is running from 1, 2, 3 and so on. Even if we put n equal to 0, actually becomes, you see that v_n is 0. So it is not an eigenvalue, corresponds to $\lambda = 0$ equal to 1. So these are your eigenvalues and eigen functions when you consider λ greater than 1. So you have another case, that is λ less than 1, if you consider this case, the general solution we can rewrite. So $y(x)$ is $c_1 e^x + c_2 e^{-\lambda x}$ is common, so you have $c_1 e^x$ and λ is negative, when λ is less than 1, this will be positive, okay, so this will be positive. So you can write as it is.

So you have, simply write $1 - \lambda x + c_2 e^{-\sqrt{1 - \lambda} x}$, okay. So now you apply the boundary conditions, $y(0) = 0$ implies $c_1 + c_2 = 0$. Okay. So that will give me $c_1 = -c_2$, so implies $y(x) = e^{\sqrt{1 - \lambda} x} (-c_2) + c_2 e^{-\sqrt{1 - \lambda} x}$ and you have c_2 , I am replacing with $-c_1$, so you have $-c_1 e^{\sqrt{1 - \lambda} x} + c_1 e^{-\sqrt{1 - \lambda} x}$. Okay. So this is what you have, so this is your general solution have to plan the boundary condition.

(Refer Slide Time: 15:36)

$\Rightarrow c_1 = 0$
 $\Rightarrow y(x) \equiv 0 \Rightarrow \lambda < 1$ is not an eigenvalue.
 Any piecewise continuous function $f(x)$, $0 < x < \pi$ can be written as
 generalised (Fourier Series) $f(x) = \sum_{n=1}^{\infty} c_n e^{i n x}$, where $\langle f(x), e^{i n x} \rangle = c_n \langle e^{i n x}, e^{i n x} \rangle$
 i.e. $c_n = \frac{\int_0^{\pi} e^{-i n x} f(x) dx}{\int_0^{\pi} e^{-i n x} e^{i n x} dx} = \frac{1}{\pi} \int_0^{\pi} e^{-i n x} f(x) dx$
 generalised (Fourier transform) $\therefore \int_0^{\pi} e^{i n x} dx = \frac{\pi}{2}$

Now you apply the boundary condition $y(\pi) = 0$, you get $c_1 e^{\sqrt{1 - \lambda} \pi} - c_1 e^{-\sqrt{1 - \lambda} \pi} = 0$. So this quantity has to be 0. And you see that this is $e^{\sqrt{1 - \lambda} \pi} - e^{-\sqrt{1 - \lambda} \pi}$. So this is infinite number. So $e^{\sqrt{1 - \lambda} \pi}$, let us call this c , $c - c^{-1} = 0$, this will never be 0. So this cannot be 0 and this cannot be 0, that means c_1 has to be 0. So that implies $y(x)$ is identically 0. That implies $\lambda < 1$ is not an eigenvalue. Because you do not have nonzero solutions for the system.

So what you have is, what you have found this, only these are your eigenvalues and these are all eigen functions. So any piecewise function, any piecewise continuous function, piecewise continuous function $f(x)$ which is the domain between 0 to π , I can write, can be written as Fourier series, Fourier series is $f(x) = \sum_{n=1}^{\infty} c_n e^{i n x}$, you have some c_n and what are your eigen functions, $e^{i n x}$, $e^{-i n x}$, okay. Where c_n is simply, we integrate, so take the dot product, where c_n are, how do we find my c_n , you mult, you just

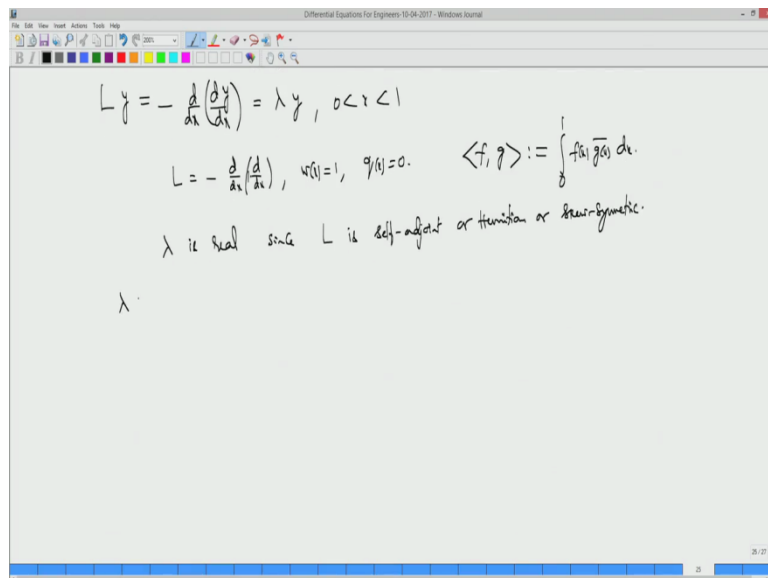

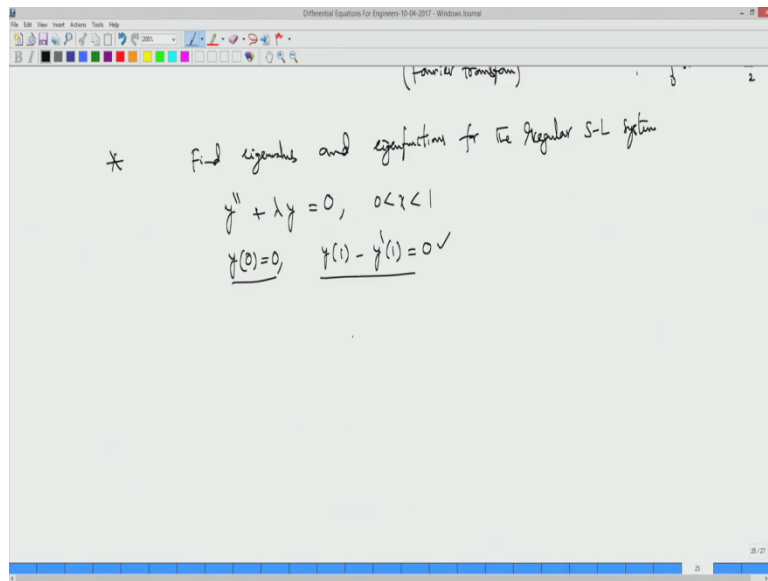

take the dot product with v_n , $e^{mx} \sin mx$ equal to, so when you multiply this $e^{mx} \sin mx$, only c_m will be contributing, m equal to n only will contribute.

So you have e^{mx} dot product $\sin nx$ $e^{mx} \sin mx$, okay. That is c_m is \int_0^π you have e^{-2x} is wet function, $e^{-2x} f(x)$, $e^{mx} \sin mx dx$. So this e^{mx} and e^{-2x} will go, so you have e^{-x} this divided by, now this one $\int_0^\pi e^{-2x} \cdot e^{mx} \sin mx dx$ whole square, so when you will square, this is what you get. So this will go, so what you get is this, this quantity is simply, because $\int_0^\pi \sin^2 mx dx$ is. You can write $\frac{1 - \cos 2mx}{2}$ from 0 to π , that value is $\frac{\pi}{2}$.

Just the half that you put the limits 0 to π , so you have $\frac{\pi}{2}$ so you have 2 by π c_m is 2 by $\pi \int_0^\pi e^{-x} f(x) \sin mx dx$. So that is what, that is what is your c_m . So these are your fourier coefficients, fourier transforms. Fourier transform with this with respect to these eigen functions, this is your fourier series, fourier series, okay. So because something 2, some simple, some other example, not from, in terms of sines and cosines, so you can say that is generalised fourier series, okay. You can say generalised fourier series and generalised fourier transform.

This, for this particular example, this particular fourier type of transform and series, okay. And this way for a piecewise continuous function $f(x)$, this convergence of this series is actually point wise. You fix x as the series, the series of numbers, this converges to a function value at the point. Okay. So look at some other examples of regular sturm louisville system, in which case, so we may not be able to explicitly your eigenvalues. Okay. Let us see that example.

(Refer Slide Time: 20:19)

One more example, with that we will wind up Sturm-Liouville theory. So you can have, so what you consider is now find eigenvalues and eigen functions for the regular Sturm-Liouville system, regular Sturm-Liouville system, that is $y'' + \lambda y = 0$, λ is a parameter and you have the domain is between 0 to 1, x is between 0 to 1 and you have $y(0) = 0$ and $y(1) - y'(1) = 0$. So because it is a regular Sturm-Liouville system you can give, this is simpler one but this is a combination of its derivative. So we have chosen combination of y and its derivative at 1, this is equal to 0.

So if you have like this, always when you take the combination, you may not be getting the solution eigenvalues explicitly, we will see how it is. So we write this as $y, \frac{dy}{dx} dx - \lambda y = 0$, this is my Ly , Ly , okay, so x is between 0 to 1. So it is already in the

self adjoint form. So l is minus $\frac{d}{dx}$ of $\frac{d}{dx}$, p is 1, 1 into $\frac{d}{dx}$ and w is 1, q is 0. So dot product of, i can define dot product here, this system is 0 to 1, w is 1, so you have simply $\int f(x) g(x) dx$. So what happens, now you find the, now it is in self adjoint form, so λ is real, since l is self adjoint, l is self adjoint or hermitian or you can say skew symmetric.

(Refer Slide Time: 22:46)

The image shows a handwritten derivation in a software window titled "Differential Equations for Engineers-10-04-2017 - Windows Journal". The text is as follows:

$$\Rightarrow \lambda > 0 \text{ or } \lambda = 0 \text{ or } \lambda < 0$$

$$\mu^2 = \lambda > 0: \quad y'' + \mu^2 y = 0, \quad 0 < x < 1$$

general solution $y(x) = C_1 \cos \mu x + C_2 \sin \mu x$

$$y(0) = 0 \Rightarrow C_1 = 0 \checkmark$$

$$\Rightarrow y(x) = C_2 \sin \mu x$$

Now you can look at all the different cases. So λ is either positive, λ equal to 0 or λ less than 0. So we look at all these cases, okay, so start with λ positive, if you take the 1, if λ is positive, so we have $y'' + \lambda y = 0$. So λ positive means $\lambda = \mu^2$, μ is positive, as usual we can think of like this, we can put $\lambda = \mu^2$. So we will get general solution, general solution $y(x)$ is $C_1 \cos \mu x + C_2 \sin \mu x$, so this is the general solution. Okay, between, x is between 0 to 1.

(Refer Slide Time: 23:58)

The image shows a software window titled "Differential Equations For Engineers 10-04-2017 - Windows Journal". The window contains handwritten mathematical work:

$$y(1) = c_2 \sin \mu$$

$$y(1) - y'(1) = 0 \Rightarrow c_2 \sin \mu - c_2 \mu \cos \mu = 0$$

$$c_2 [\sin \mu - \mu \cos \mu] = 0$$

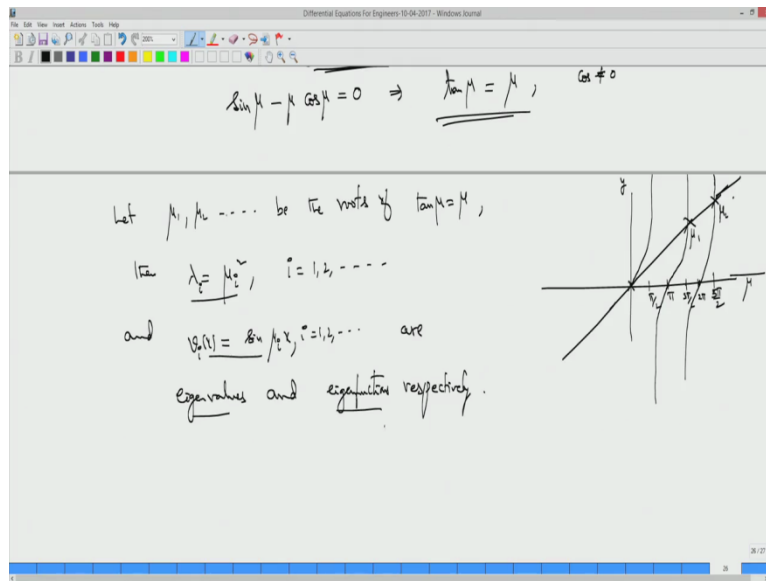

$$\sin \mu - \mu \cos \mu = 0 \Rightarrow \tan \mu = \mu, \quad \cos \mu \neq 0$$

Now when we apply the boundary condition, like earlier we have, so you have $y(0)$ is 0 will give me c_1 is 0, c_1 is 0, that is 1, $\cos 0$ is one plus c_2 into 0, that is 0. So I have c_1 which is equal to 0. So we have c_1 is 0. So general solution becomes now $c_2 \sin \mu x$. Now you apply other boundary conditions, that is y at 1 minus y' at 1 equal to 0. If you apply the boundary condition here for this, you have $c_2 \sin \mu$ minus $c_2 \mu \cos \mu$ into 1. So that this, this has to be 0, so this is nothing but $\sin \mu$ minus $\mu \cos \mu$ has to be 0. So I just have to see for those new positive values for this point is 0.

Is no such value satisfying this equation, that means c_2 has to be 0, that means all new positive are not an eigen values. But we have to see this one, this is called dispersion relation, so $\sin \mu$ minus $\mu \cos \mu$, whether it has any positive μ solutions. So this is, this is actually $\tan \mu$ equal to μ . Right. We can just divide, taking that $\cos \mu$, so we can rewrite this $\tan \mu$ equal to μ . So $\sin \mu$ divided by $\cos \mu$, that means $\cos \mu$ should not be 0, right. When $\cos \mu$ equal to 0, that is you know that these are $\pi/2$, $3\pi/2$ and so on, so these are the values, we know that this quantity is nonzero. Okay.

So this except, except that this has to be 0, so $\cos \mu$ should not be 0 when you do this one, when you divide. Suppose it is 0, okay, suppose if it is 0, that is true only at these values. But these values you can easily see that this quantity is nonzero. So these $\mu \pi/2$, $3\pi/2$, this quantity is nonzero. So you can think of other values, you can divide it and you can now find the roots of $\tan \mu$ equal to μ . Okay.

(Refer Slide Time: 26:13)

So this we do graphically, this is like let us say μ is here, this is my $\tan x$ equal to x , okay, this is your y . Y equal to μx , y equal to x is something like this line. And you have $\tan \mu$, that is $\tan x$, y equal to $\tan x$, so $\tan 0$ is 0, $\tan \pi/2$ is, only you want positive side, it $\tan \pi/2$, $\tan \pi$, $\tan 3\pi/2$ and 2π and so on. So for this you have, you have things like this, when you say $\pi/2$, it is going to infinity, so you have something like, going to infinity at $\pi/2$. Other things you will have \tan , what is the other value, so that is $\tan \pi$, and what is $\tan \pi$, $\sin \pi / \cos \pi$, so that is 0.

So it should be 0 here and here at $\pi/2$, the negative side, it should go to, it should nicely go to, eventually asymptotically this should go to minus infinity. At $3\pi/2$ it should go to asymptotically minus infinity. Again at 2π and $2\pi + \pi/2$ is $5\pi/2$. And again here you have something like this curve. Okay, this is at 2π , so like this you get. So you see that this curve and this line is touching at these points, okay. When this is 0, so we do not consider, so this is your, because μ is positive, μ is positive, so you have to worry about only this 1, this is your μ_1 , this is your μ_2 and like this and so on.

You can denote them like that and say then let μ_1, μ_2 and so on be the roots of, you have roots, that is clear from this graph, $\tan \mu$ equal to μ . Then λ is μ^2 , y is from 1, 2, 3 and so on, that is your λ_i , these are your eigenvalues for which c_2 is arbitrary. Once c_2 is arbitrary, so you have $y(x) = \sin \mu x$, $\sin \mu x$, those are your v_i of x , these are eigen functions. $\sin, \sin \mu_i, \mu_i x$. So these are eigenvalues, then these are eigenvalues. So these are, this and this are eigenvalues and eigen functions respectively. This corresponds to eigenvalue and this corresponds to eigen functions.

So you do not know explicitly exactly what are your μ 's, some values, okay. Wherever, so numerically you can find out all these values μ_1, μ_2, μ_3 and so on, there will be positive, okay. So in certain eigenvalues are eigen functions corresponding to the case μ positive, that is λ positive. Now look at the λ equal to 0 case.

(Refer Slide Time: 29:52)

The image shows a handwritten derivation in a software window titled "Differential Equations for Engineers-10-04-2017 - Windows Journal". The derivation is as follows:

$$\begin{aligned} \lambda = 0: \quad & y'' = 0 \\ & y(x) = c_1 x + c_2 \\ & y(0) = 0 \Rightarrow c_2 = 0 \\ & y(x) = c_1 x \\ & y(1) - y'(1) = 0 \Rightarrow c_1 - c_1 = 0 \\ & \Rightarrow c_1(1-1) = 0 \\ & \Rightarrow c_1 \cdot 0 = 0 \\ & \Rightarrow c_1 \text{ is arbitrary.} \end{aligned}$$

Now you know that general solution of the equation is $y'' = 0$ is equation 1 λ equal to 0. So the general solution is $c_1 x + c_2$, you apply the boundary condition $y(0) = 0$ will give me $c_1 \cdot 0 + c_2$, so that will give me $c_2 = 0$, okay. So $y(x)$ becomes $c_1 x$, now you apply the other boundary condition $y(1) - y'(1) = 0$. So this will give me $c_1 - c_1$, this derivative, that is also c_1 , which is 0, it is satisfying. So you see that, you take any arbitrary value of c_1 , so that means nonzero value of c_1 , it is actually satisfying the 2nd boundary condition which is satisfied, okay.

So that means, so this is something like, see what you have is $c_1 \cdot 1 - 1 = 0$. So you have $c_1 \cdot 0 = 0$. That means c_1 is arbitrary. Once you have c_1 arbitrary, the general solution is this one. So you have nonzero solution, so this implies $\lambda = 0$ is an eigenvalue. And we call this $\lambda = 0$ corresponding to $v = 0$. So v_0 of x , corresponding eigen function I am denoting as v_0 which is, we can take c_1 as 1, so you have this is x , is corresponding eigen function.

(Refer Slide Time: 31:37)

$\lambda < 0: \lambda = -\mu^2, \mu > 0.$
 $y'' - \mu^2 y = 0$
 $y(x) = c_1 e^{\mu x} + c_2 e^{-\mu x}$
 $y(0) = 0 \Rightarrow c_1 + c_2 = 0 \Rightarrow c_1 = -c_2$
 $\Rightarrow y(x) = c_1 (e^{\mu x} - e^{-\mu x}) = 2c_1 \sinh \mu x$
 $y(1) - y'(1) = 0 \Rightarrow 2c_1 \sinh \mu - 2c_1 \mu \cosh \mu = 0$
 $\Rightarrow c_1 [\sinh \mu - \mu \cosh \mu]$

Now look at the case lambda negative, that means lambda equal to minus mu square with mu positive. In this case, what is your y double dash, minus mu square y equal to 0, this is how the equation becomes, general solution of this equation is c1 e power mu x plus c2 e power minus qx. You apply the boundary conditions now we will give me c1 plus c2 equal to 0, that will give me c1 equal to minus c2. This implies solution becomes, general solution becomes c1 times e power mu x minus c2 i am replacing with minus c1 so you have e power minus mu x. Okay.

So now you apply, this is actually equal to c1, 2 c1 and this is sin hyperbolic mu x, mu is positive, okay. So now you apply the other boundary condition, y at 1 minus y - at 1 equal to 0 will give me for this, we are 2 c1 sin hyperbolic mu - 2 c1 mu cos hyperbolic mu equal to 0. So this will give me 2 c1, 2 cannot be 0, so this has to be c1 times sin hyperbolic mu minus mu cos hyperbolic mu has to be 0. So this i just have to check whether for some positive mu values this quantity is 0. So again we do the same thing, so to check this sin hyperbolic mu minus mu cos hyperbolic mu equal to 0, that is we can do if this is tan hyperbolic mu equal to mu if cos hyperbolic mu is not equal to 0, because you are dividing with it.

(Refer Slide Time: 34:16)

$$y(0) = 0 \Rightarrow c_1 + c_2 = 0 \Rightarrow c_1 = -c_2$$

$$\Rightarrow y(x) = c_1 (e^{\mu x} - e^{-\mu x}) = 2c_1 \sinh \mu x$$

$$y'(x) - y'(0) = 0 \Rightarrow 2c_1 \cosh \mu x - 2c_1 \mu \cosh \mu = 0$$

$$\Rightarrow c_1 [\sinh \mu x - \mu \cosh \mu] = 0$$

$$\sinh \mu x - \mu \cosh \mu = 0$$

$$\Rightarrow \tanh \mu = \mu, \quad \because \cosh \mu \neq 0.$$

$$\Rightarrow \text{For no nonzero } \mu \text{ satisfying } \tanh \mu = \mu.$$

But this will never be 0, this will never be 0 for any μ positive value. Actually you can do it, okay, it is not just is the cos since this is nonzero, you can always divide. Do you look at this tan hyperbolic plot and this y equal to μ plot. This is y equal to μ and you plot tan hyperbolic μ , they never touch anywhere, okay. You can just do it, they do not touch any other place. So you can plot it and see tan hyperbolic μ do not have any solution, nonzero solution. Okay, positive solution, strictly positive μ , you do not have any solution.

Actually touching and above it goes, simply goes above, only touching at 0, this is the only route but that is μ equal to 0. So implies for a nonzero μ , no nonzero, no nonzero μ satisfying tan hyperbolic μ equal to μ . That means, that implies for μ positive this quantity sin hyperbolic μ minus μ cos hyperbolic μ is nonzero. That means by looking at this c has to be 0, c_1 has to be 0.

(Refer Slide Time: 35:03)

$$\sinh \mu - \mu \cosh \mu = 0$$

$$\Rightarrow \tanh \mu = \mu, \quad \because \cosh \mu \neq 0.$$

$$\Rightarrow \text{For non-zero } \mu \text{ satisfying } \tanh \mu = \mu$$

$$\Rightarrow \text{For } \mu > 0, \sinh \mu - \mu \cosh \mu \neq 0.$$

$$\Rightarrow c_1 = 0$$

$$\Rightarrow y(x) = 0, \quad 0 < x < 1$$

$$\Rightarrow \lambda < 0 \text{ is not an eigenvalue.}$$

That implies the general solution becomes, earlier after applying the 1st boundary condition over general solution is this, now that you found c_1 is 0, that means this is completely 0 between 0 to 1. That means lambda negative is not an eigenvalue. Any lambda negative is not an eigenvalue. So what you found is finally you have only, you have this is one eigen function corresponding to 0 and the other eigenvalues and eigen functions which form μ_i 's $\sin \mu_i$'s, μ_i is satisfying than μ equal to μ . So now you know what are your eigenvalues and eigenvectors, as usual you can write the fourier transforms and fourier series in this case.

(Refer Slide Time: 35:59)

Any piecewise continuous function $f(x)$, $0 < x < 1$ is written as

$$f(x) = \frac{a_0}{2} + \sum_{n=1}^{\infty} C_n \frac{\sin n\pi x}{\sin n\pi}$$

(Fourier series)

where $\langle f(x), x \rangle = C_0 \langle x, x \rangle$

$$\langle f(x), \frac{\sin n\pi x}{\sin n\pi} \rangle = C_n \langle \frac{\sin n\pi x}{\sin n\pi}, \frac{\sin n\pi x}{\sin n\pi} \rangle$$

ie,

$$\begin{cases} C_0 = 2 \int_0^1 f(x) x \, dx & \int_0^1 x^2 \, dx = \frac{x^3}{3} \Big|_0^1 \\ C_n = \frac{\int_0^1 f(x) \frac{\sin n\pi x}{\sin n\pi} \, dx}{\int_0^1 \frac{\sin n\pi x}{\sin n\pi} \, dx} \end{cases}$$

(Fourier transform)

So any piecewise continuous function $f(x)$ which is defined between 0 to 1, is written as $f(x) = \sum_{n=1}^{\infty} c_n \sin(n\pi x)$ which is equal to, what you have, it is running from, n is running from 0 to infinity, 1 to infinity is what you have for λ positive and $n\lambda = 0$ corresponding to $n = 0$. So you have c_n and what is your functions, v_n , so those are $\sin(n\pi x)$ and x , you have 2 such things. So you have, you can rewrite like c_0 into x , that is one corresponding to $\lambda = 0$, and these things you can sum it up, with n is from 1 to infinity and you have $c_n \sin(n\pi x)$. Okay.

So you have these are your eigen functions $\sin(n\pi x)$, so n will just change the index as n . Okay. Where c_n , so how do you get your c_0 , c_0 you should get it from, by, this is your eigen function, this is your eigen function, so by multiplying this eigen function x and take the dot product with f you can get your c_0 x , x . Okay. And this if you take, your dot product with $\sin(n\pi x)$, later $\sin(n\pi x)$, you write $\sin(m\pi x)$, you can get c_m got up with $\sin(m\pi x)$, $\sin(m\pi x)$, okay. So what are these, so you can think of c_0 is $\int_0^1 f(x) dx$, n do not have, so the weight function is only 1, so it is usual dot product $f(x)$ into $x dx$, between 0 to 1 into the real part, so does not matter.

So you have to divide by $\int_0^1 x^2 dx$, so you have to write $\int_0^1 x^2 dx$. That is $\frac{1}{3}$ between 0 to 1, so which is $\frac{1}{3}$. So you have $\frac{1}{3}$, so you have total 3. So you finally get c_0 as this one between this. And c_m has $\int_0^1 f(x) \sin(m\pi x) dx$ divided by this, because you do not know what is exactly your μ_m , we cannot, may not be able, you can actually find $\int_0^1 \sin^2(m\pi x) dx$. This you can calculate and put it, this is how you find this. So these are your fourier transform, generalised fourier transforms and this is your fourier series. You can think of $f(x)$ as the signal, you can split it into discrete frequencies, at these frequencies you can have these solutions, okay.

These are your discrete frequencies, so we have 1 to, 0 to infinity. So divide by frequency, you split the signal, since we have this fourier transform, you can get back your signal by combining all of these discrete frequencies, okay, in these functions. So this is how you can get eigenvalues and eigen functions. So here you got implicitly, so you would not find explicitly these eigenvalues and eigen functions, right. So this is the example I will tell you story. So this is our Sturm-Liouville theory, so what you will learn from this Sturm-Liouville theory is it is just the property of second-order linear differential equation, okay, ordinary differential equation.

So using this you can actually develop what is the fourier transform and fourier series of a, of a function defined on a finite interval. So if you think of this as a real line which is a periodic function, okay. And that finite interval is whatever is defined repeated everywhere as periodically. So such a thing you can represent as the fourier series in terms of eigenvalues and eigen functions. Okay. So another use of this sturm louisville theory is you try to extract these sturm louisville problem when you solve partial differential equations in a simpler domains, that we will do in the future videos, okay.

So when you are solving these partial differential equations, in a simpler domains, such as rectangular or circular or elliptical domains, you may have to convert, you may have to extract, the main idea is to how will you solve this partial differential equation, idea is to extract, if you can extract this sturm louisville problem out of the boundary value problem, whatever you have for the partial differential equation, then you get all the solutions, eigenvalues and eigen functions of the corresponding whatever you get extracted sturm louisville problem, using them you combine them, you make a general solution of the pde and get back your unknowns. And take a linear superposition because it is a linear equation, you can only solve linear partial differential equations on a simpler domains using this sturm louisville problems. That we will see in the next videos.
