In today's lecture we shall see how we can develop some numerical integration methods

(Refer Slide Time: 00:24)

So we work out the details for error in Trapezoidal rule. So what is the error in  $f(x)$  minus  $p_1(x)$  and we have already obtained the expression for error in interpolation at any  $x$  which belongs to the interval  $x_0$  to  $x_1$ . So what is the error in the interpolation it is  $f(x)$  minus  $p_1(x)$  and that is equal to the second derivative evaluated at  $\xi$  divided by 2 factorial multiplied by  $(x - x_0)$  into  $(x - x_1)$  for  $\xi$  lying between  $x_0$  and  $x_1$ .

(Refer Slide Time: 01:25)

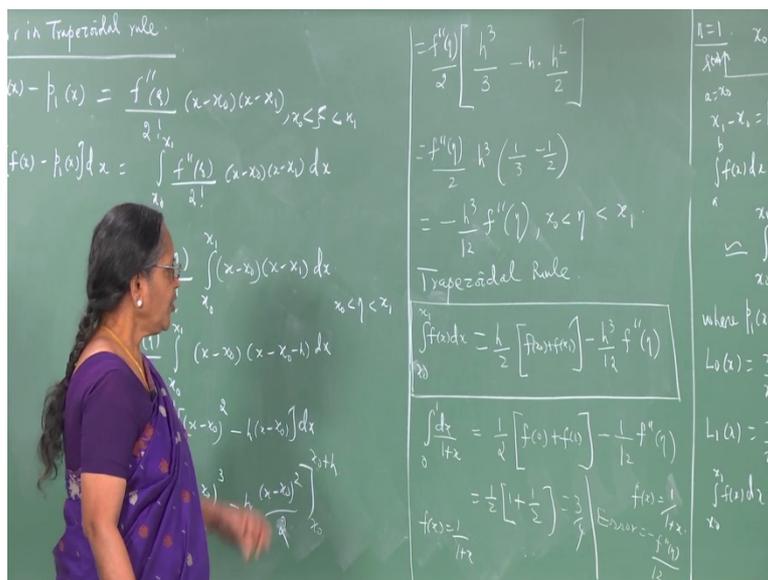

Error in Trapezoidal rule:  
 $f(x) - p_1(x) = \frac{f''(\eta)}{2!} (x-x_0)(x-x_1), x_0 < x < x_1$   
 $\int_{x_0}^{x_1} [f(x) - p_1(x)] dx = \int_{x_0}^{x_1} \frac{f''(\eta)}{2!} (x-x_0)(x-x_1) dx$   
 $= \frac{f''(\eta)}{2!} \int_{x_0}^{x_1} (x-x_0)(x-x_1) dx$   
 $= \frac{f''(\eta)}{2} \int_{x_0}^{x_0+h} [(x-x_0)^2 - h(x-x_0)] dx$   
 $= \frac{f''(\eta)}{2} \left[ \frac{(x-x_0)^3}{3} - h \frac{(x-x_0)^2}{2} \right]_{x_0}^{x_0+h}$

And therefore error in this evaluation of the definite integral will be obtained by integrating the error in interpolation between  $x_0$  and  $x_1$ . So  $\int_{x_0}^{x_1} [f(x) - p_1(x)] dx$  will be equal to  $\int_{x_0}^{x_1} \frac{f''(\eta)}{2!} (x-x_0)(x-x_1) dx$ . So by using mean value theorem for integral calculus we have  $f''(\eta)$  by  $2!$  factorial  $\int_{x_0}^{x_1} (x-x_0)(x-x_1) dx$ .

So  $\eta$  is now in  $x_0$  to  $x_1$ . So this will give you  $f''(\eta)$  by factorial 2 into let us evaluate this so  $\int_{x_0}^{x_1} (x-x_0)(x-x_1) dx$ . So that gives you  $f''(\eta)$  by 2 into  $\int_{x_0}^{x_0+h} [(x-x_0)^2 - h(x-x_0)] dx$  and that must be integrated with respect to  $x$ .

So by 2 into  $\int_{x_0}^{x_0+h} [(x-x_0)^2 - h(x-x_0)] dx$  between the limits  $x_0$  and  $x_0+h$ .

(Refer Slide Time: 03:20)

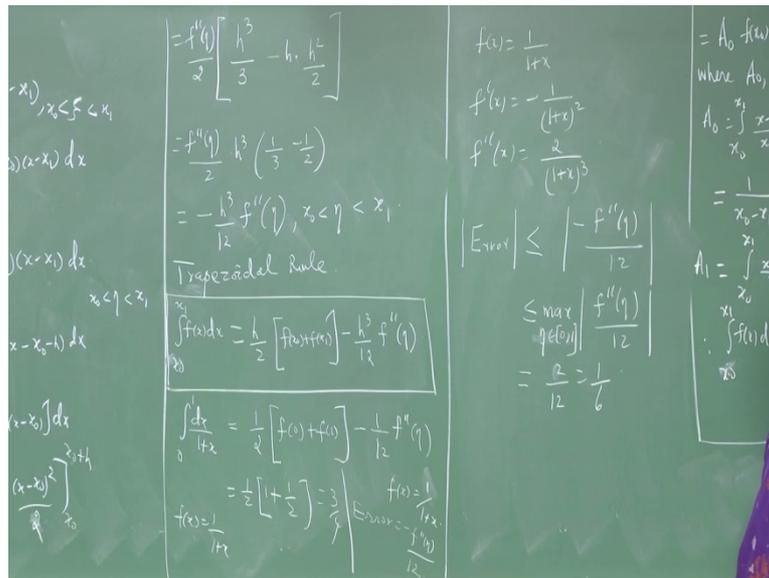

So this is  $f''(\eta)$  by 2 into at the upper limit  $x_0 + h$  this will give you  $x_0 + h$  minus  $x_0$ . So  $h^3$  by 3 and at the lower limit this will vanish and the next term minus  $h$  into at the upper limit  $x_0 + h$  this will give you  $h^2$  by 2] and at the lower limit this will vanish. So this will give  $f''(\eta)$  by 2 into  $h^3$  into  $(\frac{1}{3} - \frac{1}{2})$  so that will give you minus  $h^3$  by 12 into  $f''(\eta)$  lying between  $x_0$  and  $x_1$ .

So error in Trapezoidal rule is this where  $h$  is the step size namely the width of the interval.. So you now can write down the Trapezoidal rule as if you want integral  $x_0$  to  $x_1$   $f(x) dx$  then it is  $h$  by 2 into  $f(x_0) + f(x_1)$  plus the error namely minus  $h^3$  by 12 into the second derivative ( $\eta$ ).

So if I ask you to evaluate integral say 0 to 1  $dx$  by  $1+x$  by Trapezoidal rule, then it is simply  $h$  is 1 because  $b - a$  into  $[f(0) + f(1)]$  and by doing this you have made an error of  $h$  is 1 so  $1$  by 12 into  $f''(\eta)$  where  $f(x)$  is  $1 + x$ .

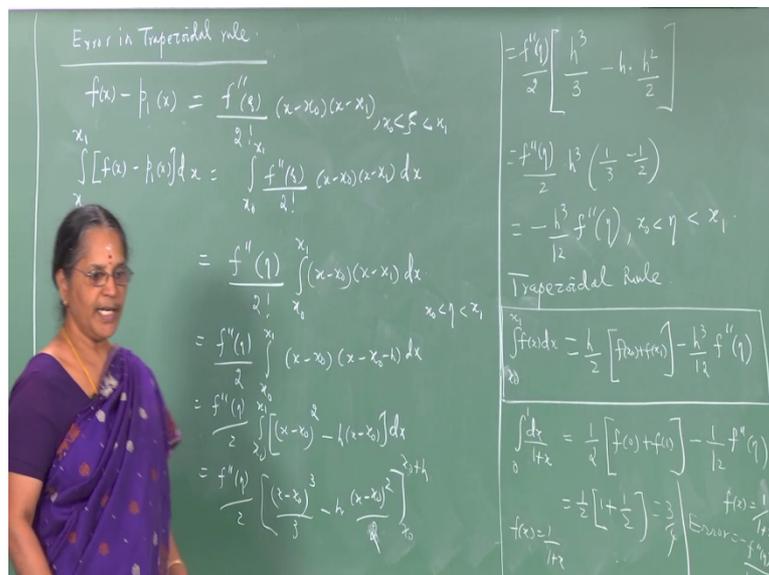

So this essentially will give you half of  $f(0)$ ,  $f(x)$  is  $1 + x$  so  $f(0)$  is 1 plus  $f(1)$  is half so the result is  $3/4$  then the error committed is minus  $f''(\eta)$  divided by 12. So if you want the bound on the error then it will be the absolute value of  $f''(\eta)$  by 12 knowing  $f(x)$  which is  $1 + x$  you can compute the second derivative.

(Refer Slide Time: 06:19)

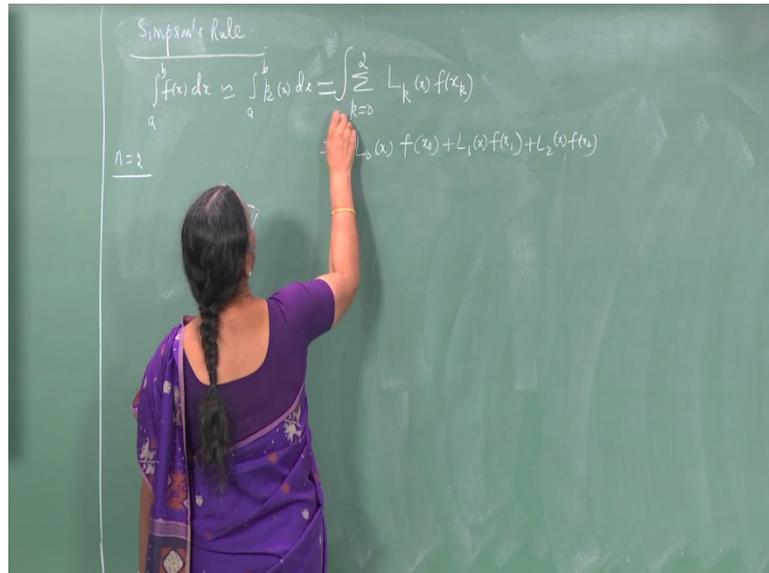

So the second derivative will be  $f(x)$  is 1 by 1 plus x  $f'$  dash (x) will be minus 1 by (1 plus x) the whole square and  $f''$  double dash(x) will be 2 by (1 plus x) the whole cube. So if I want the bound on this error then this will be minus  $f''$  double prime(eta) by 12 and so I observe that this will be less than or equal to the maximum of  $f''$  double prime (eta) by 12 and so for maximum I take this eta belonging to the interval 0 to 1. Having computed the second derivative I observe that the maximum will occur at x is equal to 0 and therefore it is 2, so the result is 2 by 12 and so 1 by 6. So the error is always bounded by 1 by 6 in this approximation of the interval which is given by this.

(Refer Slide Time: 07:40)

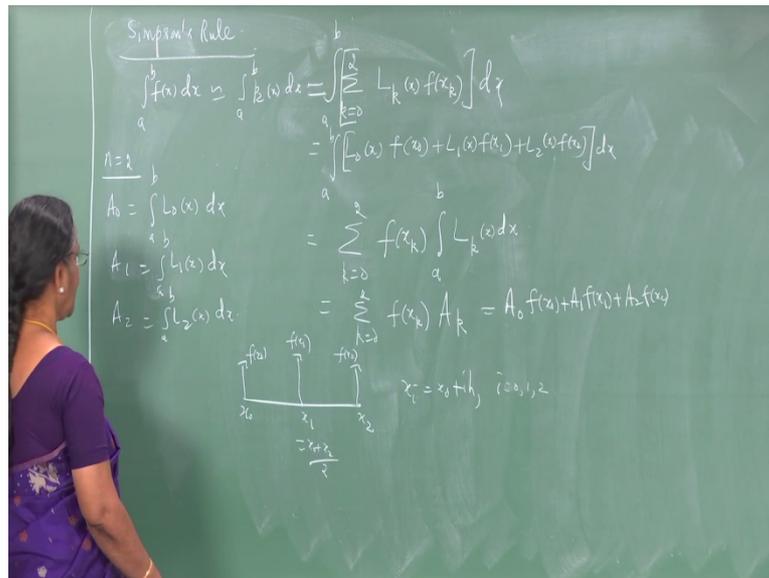

So this method was obtained by approximating  $f(x)$  by a linear polynomial, So we move ahead to see what happens if we approximate  $f(x)$  by a second degree polynomial namely a quadratic interpolation polynomial the resulting method that we get is called Simpson's rule. So we shall derive now Simpson's rule.

(Refer Slide Time: 08:11)

The method is obtained by approximating the function  $f(x)$  which has to be evaluated in this interval by a polynomial of degree 2. So I take my  $n$  to be 2 because I am interested in deriving Newton codes method. So I would like to get a method which is of the form  $\sum_{k=0}^2 L_k(x) f(x_k)$ . So this will be  $L_0(x) f(x_0)$  plus  $L_1(x) f(x_1)$  plus  $L_2(x) f(x_2)$ .

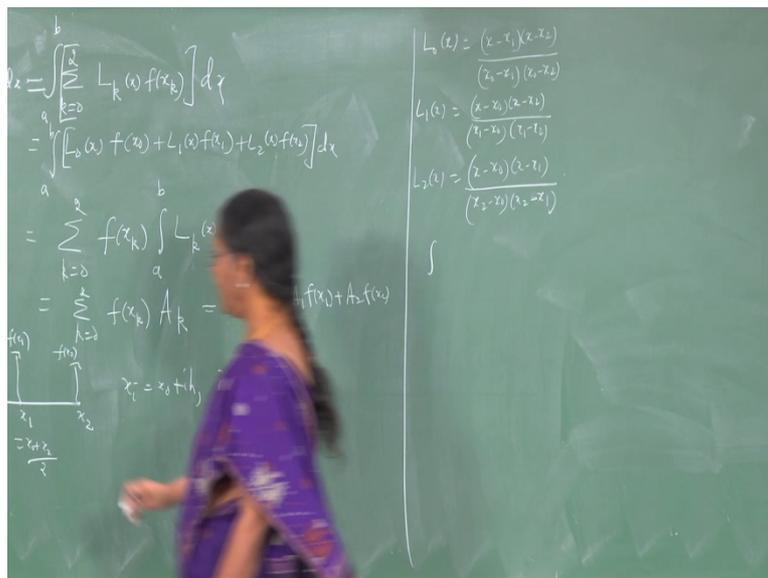

(Refer Slide Time: 09:14)

So I have to integrate this with respect to  $x$ , so integral of this with respect to  $x$ , so which will give me  $\sum_{k=0}^2 f(x_k) \int_a^b L_k(x) dx$  for  $k$  is equal to 0 to 2. So this will be  $k$  equal to 0 to 2  $f(x_k)$ , I shall call this integral  $L_k(x) g(x)$  to be  $A_k$ . So I am interested in getting the constants  $A_0$ ,  $A_1$ , and  $A_2$  in this formula where  $A_0$  will be equal to integral  $a$  to  $b$   $L_0(x) dx$ ,  $A_1$  is integral  $a$  to  $b$   $L_1(x) dx$ , and  $A_2$  is integral  $a$  to  $b$   $L_2(x) dx$ .

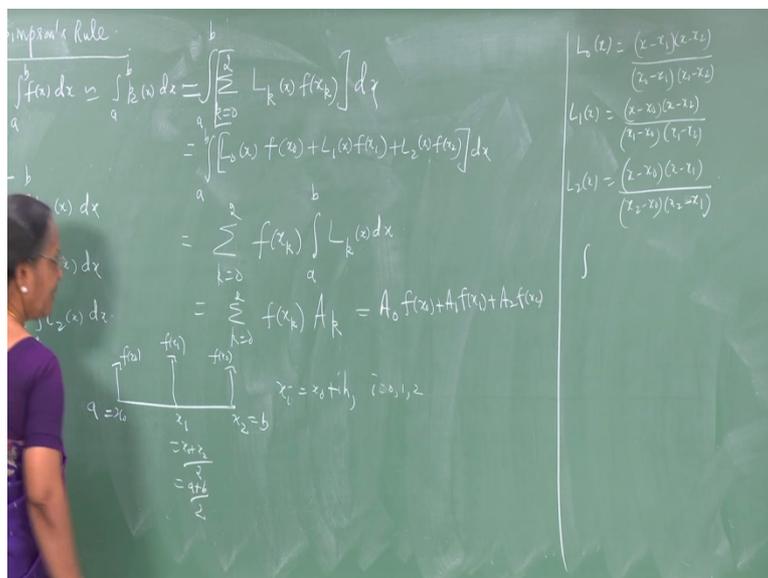

So I require three points  $x_0$ ,  $x_1$ ,  $x_2$  and we are deriving Newton codes method. So the points must be equally spaced so I shall take the points  $x_0$ ,  $x_1$  and  $x_2$  to be such that  $x_i$  is  $x_0$  plus  $ih$  for  $i$  is equal to 0,1,2. So my  $x_1$  is nothing but  $x_0$  plus  $x_2$  by 2 the mid point of the interval. So I evaluate the ordinates at these points. So I have the information about the ordinates because I know what  $f(x)$  is? If I evaluate  $A_0$ ,  $A_1$ ,  $A_2$  then I will have the formula where  $f(x)$  is approximated by a quadratic interpolation polynomial.

(Refer Slide Time: 11:25)

So we write down what these  $L_i(x)$  are so  $L_0(x)$  is equal to  $(x - x_1)(x - x_2)$  by  $(x_0 - x_1)(x_0 - x_2)$ .  $L_1(x)$  will be  $(x - x_0)(x - x_2)$  by  $(x_1 - x_0)(x_1 - x_2)$  and  $L_2(x)$  is  $(x - x_0)(x - x_1)$  by  $(x_2 - x_0)(x_2 - x_1)$ . So I have integral  $a$  to  $b$  what is my  $a$ ?

(Refer Slide Time: 12:15)

$a$  is  $x_0$  and  $b$  is  $x_2$  and the midpoint is  $a + b$  by  $2$ .

(Refer Slide Time: 12:25)

The image shows a chalkboard with handwritten mathematical work. On the left, there is a partial expression  $f(x) dx$  and  $A_0 f(x)$ . The main work is as follows:

$$L_0(x) = \frac{(x-x_1)(x-x_2)}{(x_0-x_1)(x_0-x_2)} = \frac{(x-x_0+h)(x-x_0-2h)}{(-h)(-2h)} = \frac{(x-x_0)^2 - 3h(x-x_0) + 2h^2}{2h^2}$$

$$L_1(x) = \frac{(x-x_0)(x-x_2)}{(x_1-x_0)(x_1-x_2)}$$

$$L_2(x) = \frac{(x-x_0)(x-x_1)}{(x_2-x_0)(x_2-x_1)}$$

$$\int_{x_0}^{x_0+2h} L_0(x) dx = \int_{x_0}^{x_0+2h} \left[ \frac{(x-x_0)^2}{2h^2} - \frac{3h(x-x_0)}{2h^2} + \frac{2h^2}{2h^2} \right] dx$$

$$= \frac{1}{2h^2} \left[ \frac{(x-x_0)^3}{3} - \frac{3h(x-x_0)^2}{2} + 2h^2 x \right]_{x_0}^{x_0+2h}$$

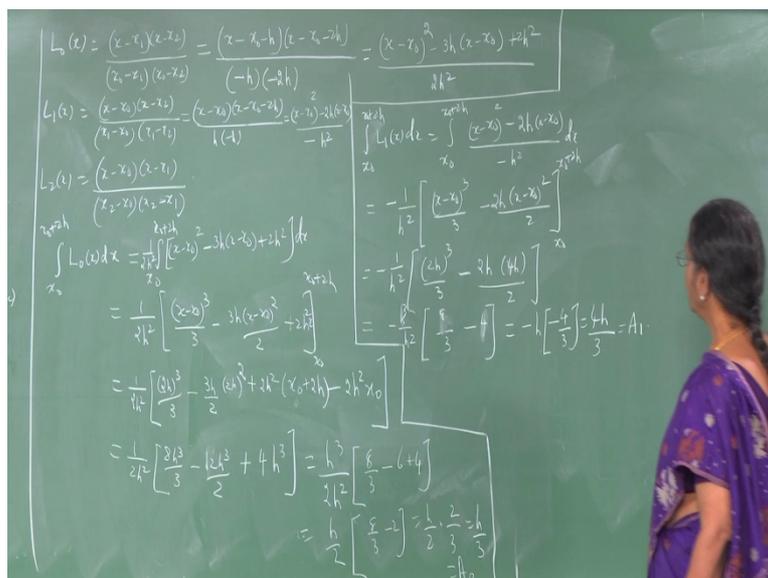

$$= \frac{1}{2h^2} \left[ \frac{(2h)^3}{3} - \frac{3h(2h)^2}{2} + 2h^2(x_0+2h) - \left( \frac{0^3}{3} - \frac{3h(0)^2}{2} + 2h^2 x_0 \right) \right]$$

$$= \frac{1}{2h^2} \left[ \frac{8h^3}{3} - \frac{6h^3}{2} + 2h^2 x_0 + 4h^3 - 2h^2 x_0 \right] = \frac{1}{2h^2} [8h^3 - 6h^3 + 4h^3] = \frac{1}{2h^2} [2h^3] = \frac{2h^3}{2h^2} = h$$

So I require integral  $x_0$  to  $x_0 + 2h$  of  $L_0(x) dx$ . So I can rewrite this as  $(x - x_0 + h)^2$  by  $(x_0 - x_0 - h)$  is  $(-h)$ ,  $(x_0 - x_0 - 2h)$  is  $(-2h)$ , so I have  $(x - x_0)$  the whole square then minus  $3h$  into  $(x - x_0)$  plus  $2h$  square divided by  $2h$  square.

So this will give me the integral  $x_0$  to  $x_0 + 2h$   $(1 \text{ by } 2h)^2$  into  $(x - x_0)$  the whole square minus  $3h$  into  $(x - x_0)$  plus  $2h$  square integrated with respect to  $x$ . So you have  $h^3$  by  $2h^2$  into  $[8 \text{ by } 3 \text{ minus } 6 \text{ plus } 4]$  so  $h$  by  $2$  into  $[8 \text{ by } 3 \text{ minus } 2]$  so  $h$  by  $2$  into  $[2 \text{ by } 3]$  so you end up with  $h$  by  $3$  that is integral  $L_0(x) dx$ . So similarly we must evaluate integral  $L_1(x) dx$  and  $L_2(x) dx$ . And what is it that we have got we have obtained a value of the constant  $A_0$  which is integral  $L_0(x) dx$ .

(Refer Slide Time: 14:20)

So let us now compute  $A_1$ , so let us simplify  $L_1(x)$  so  $x$  is  $x_0$  into  $(x - x_0 - 2h)$  by  $(x_1 - x_0)$  is  $h$   $(x_1 - x_2)$  is  $(-2h)$  so this gives you  $(x - x_0 - 2h)$  the whole square  $(-2h)$  into  $(x - x_0)$  by  $(-h)$  square. So integral  $x_0$  to  $x_0 + 2h$  of  $L_1(x) dx$  will be integral  $x_0$  to  $x_0 + 2h$   $(x - x_0 - 2h)^2$  into  $(x - x_0)$  by  $(-h)^2$  into  $dx$ .

So minus 1 by  $h^2$  into let us evaluate  $(x - x_0 - 2h)^3$  by 3 minus  $2h$  into  $(x - x_0 - 2h)^2$  by 2 between  $x_0$  and  $x_0 + 2h$ . So that gives you minus 1 by  $h^2$  square at the upper limit it is  $2h$  the whole cube by 3 minus  $2h$  into  $2h$  the whole square by 2. So that gives you minus  $h$  into minus 4 by 3 and so the constant  $A_1$  is  $4h$  by 3. Similarly we evaluate integral  $L_2(x) dx$ .

(Refer Slide Time: 16:08)

The chalkboard contains the following derivations:

$$L_2(x) = \frac{(x-x_1)(x-x_2)}{(x-x_1)(x-x_2)} = \frac{(x-x_0-h)(x-x_0-h)}{(x-x_0-h)(x-x_0-h)} = \frac{(x-x_0)^2 - 2h(x-x_0) + h^2}{(x-x_0)^2 - 2h(x-x_0) + h^2}$$

$$L_2(x) = \frac{(x-x_0)^2 - 2h(x-x_0) + h^2}{(x-x_0)^2 - 2h(x-x_0) + h^2} = \frac{(x-x_0)^2 - 2h(x-x_0) + h^2}{(x-x_0)^2 - 2h(x-x_0) + h^2}$$

$$L_2(x) = \frac{(x-x_0)^2 - 2h(x-x_0) + h^2}{(x-x_0)^2 - 2h(x-x_0) + h^2} = \frac{(x-x_0)^2 - 2h(x-x_0) + h^2}{(x-x_0)^2 - 2h(x-x_0) + h^2}$$

$$\int_{x_0}^{x_0+2h} L_2(x) dx = \int_{x_0}^{x_0+2h} \frac{(x-x_0)^2 - 2h(x-x_0) + h^2}{(x-x_0)^2 - 2h(x-x_0) + h^2} dx$$

$$= \int_{x_0}^{x_0+2h} 1 dx = [x]_{x_0}^{x_0+2h} = x_0 + 2h - x_0 = 2h$$

$$A_0 = \frac{1}{2h^2} \left[ \frac{8h^3}{3} - \frac{4h^3}{2} + 4h^3 \right] = \frac{1}{2h^2} \left[ \frac{8h^3}{3} - 2h^3 + 4h^3 \right] = \frac{1}{2h^2} \left[ \frac{8h^3}{3} + 2h^3 \right] = \frac{1}{2h^2} \left[ \frac{8h^3 + 6h^3}{3} \right] = \frac{1}{2h^2} \left[ \frac{14h^3}{3} \right] = \frac{7h}{3}$$

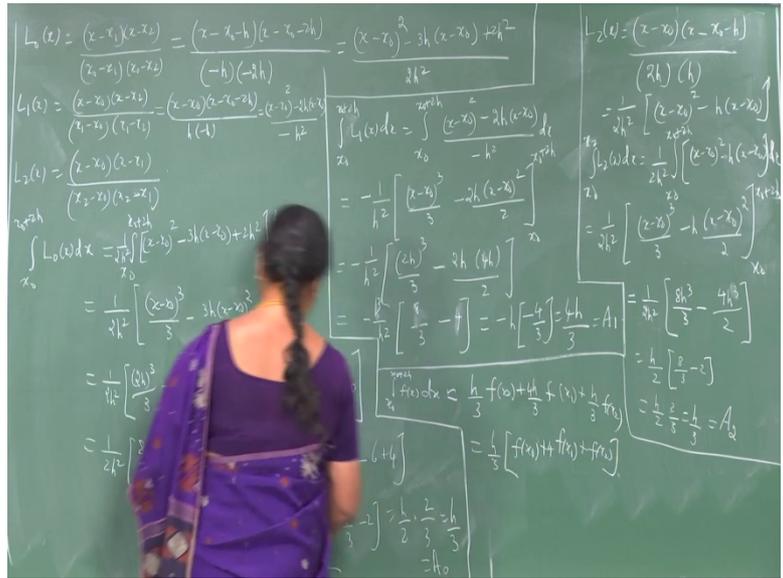

$$A_1 = -\frac{1}{h} \left[ \frac{-4}{3} \right] = \frac{4h}{3}$$

$$A_2 = \frac{1}{2h^2} \left[ \frac{8h^3}{3} - \frac{4h^3}{2} \right] = \frac{1}{2h^2} \left[ \frac{8h^3}{3} - 2h^3 \right] = \frac{1}{2h^2} \left[ \frac{8h^3 - 6h^3}{3} \right] = \frac{1}{2h^2} \left[ \frac{2h^3}{3} \right] = \frac{h}{3}$$

So let us simplify  $L_2(x)$  which is  $x$  minus  $x_0$  into  $x$  minus  $x_1$  so  $x_0$  minus  $h$   $x_2$  minus  $x_0$  which  $2h$   $x_2$  minus  $x_1$  is  $2h$  square into  $x$  minus  $x_0$  the whole square minus  $h$  into  $x$  minus  $x_0$ . So integral  $x_0$  to  $x_0 + 2h$   $L_2(x)$   $dx$  will be  $1$  by  $2h$  square integral  $x_0$  to  $x_0 + 2h$   $(x - x_0)^2 - 2h(x - x_0) + h^2$  integrated with respect to  $x$ . So this will give you  $1$  by  $2h$  square into first term integrated will give you  $x$  minus  $x_0$  the whole cube by  $3$  minus  $h$  into  $x$  minus  $x_0$  whole square by  $2$  between  $x_0$  and  $x_0 + 2h$ .

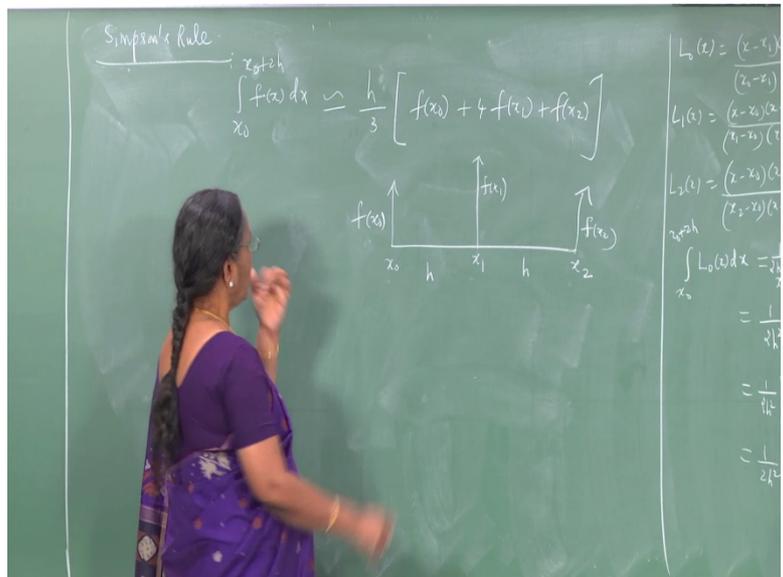

So applying the limits of integration so  $1$  by  $2h$  square  $(x_0 + 2h)$  this will give you  $2h$  the whole cube so  $8h^3$  by  $3$  this will give you  $x$  minus  $x_0$  will be  $x_0 + 2h$  minus  $x_0$  so  $2h$  the whole square divided by  $2$  into  $h$  so this will be  $h$  cube at the lower limit they vanish so this gives you  $h$  cube  $2h$  square  $h$  by  $2$  into  $8$  by  $3$  minus  $2$  so  $h$  by  $2$  into  $2$  by  $3$  and the constant is  $h$  by  $3$  so what we have evaluated is  $A_2$ . So we have the constants  $A_0$   $A_1$  and  $A_2$  determined.

(Refer Slide Time: 18:15)

So we write down the method which says integral  $x_0$  to  $x_0 + 2h$   $f(x) dx$  is  $A_0$  which is  $h$  by  $3$  into  $f(x_0)$  plus  $A_1$  which is  $4h$  by  $3$  into  $f(x_1)$  plus  $A_2$  which is  $h$  by  $3$  into  $f(x_2)$  and so this gives you  $h$  by  $3$  into  $f(x_0)$  plus  $4f(x_1)$  plus  $f(x_2)$ . So let us see what this formula tells us.

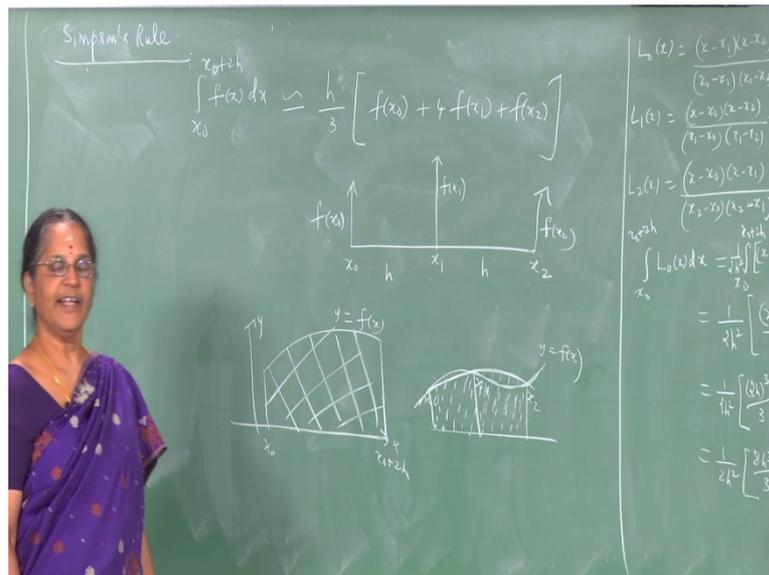

(Refer Slide Time: 19:00)

If we want to evaluate integral  $f(x) dx$  between  $x_0$  to  $x_0 + 2h$  then it is  $h$  by  $3$  times  $f(x_0)$  plus  $4$  times  $f(x_1)$  plus  $f(x_2)$ . So namely if  $x_0, x_1, x_2$  are equally spaced such that the step size the distance between any two points is  $h$  then the formula tells this integral has a value

which is approximate and is given by 1 third of this h multiplied by the sum of the n ordinates namely  $f(x_0)$  plus  $f(x_2)$  plus 4 times the ordinate at  $(x_1)$  so  $4 f(x_1)$  it is easy to remember applying Simpson's rule it is equivalent to getting the sum of the n ordinate values plus 4 times the intermediate ordinate namely the ordinate the midpoint of the two end points and multiplying it by h by 3. What does it actually mean let us see geometrically?

(Refer Slide Time: 20:38)

So we have in the xy plane a curve  $y$  is equal to  $f(x)$  and we are asked to integrate between  $x_0$  to  $x_0 + 2h$  namely we are asked to get the value of  $I$  mean we are asked to find the area bounded by  $y$  is equal to  $f(x)$  the ordinate at  $(x_0)$  and  $x_2$  and the  $x$  axis between  $x_0$  and  $x_2$ . So what did we do? We approximated this function  $f(x)$  by a parabola passing through the points  $x_0$ ,  $x_1$  and  $x_2$ .

So we have a quadratic interpolation polynomial namely a parabola passing through these three points so that this parabola approximates this curve which is equal to  $f(x)$ . Alright and we have evaluated the area which is now this bounded by the parabola which is this the axis at that point clear? Our parabola is here this is our parabola passing through the three points right?

So the shaded region is area that we have computed so in doing that we have committed an error namely this part of the area has been omitted and this part of the area has been included and so some amount of error has incurred in obtaining this integration method namely in Simpson's rule.

So our goal now is to see how much of error is incurred in obtaining Simpson's rule and ask before we can get this error by integrating the corresponding expression for error in interpolation.

So we observe that we have derived Newton codes formulas by approximating a function in an interval by a linear polynomial and we obtained Trapezoidal rule and by a quadratic interpolation polynomial and we obtained Simpson's rule and these rules are valid for the case when the nodes are equally spaced and geometrically they represent the corresponding areas bounded by a Trapezium in the case of Trapezoidal rule and the area bounded by a parabola passing through the three points  $x_0, f(x_0)$ ,  $x_1, f(x_1)$  and  $x_2, f(x_2)$  and the ordinates of the end points and the segment along the x axis between the end points.

That is the geometric way of looking at this Newton codes formulas where n is equal to 1 and n is equal to 2. So one thing that remains to be done is computation of the error in Simpson's rule method for evaluating and integral.
