Numerical integration 5
Gaussian Quadrature (Two point Method)

(Refer Slide Time: 00:16)

So let us now discuss another numerical method which is called Gaussian Quadrature. In deriving Trapezoidal rule and Simpson's rule we observed that Trapezoidal rule involved function evaluation at two points. So there are two ordinates which have to be computed. And the method is exact for polynomial of degree upto 1.

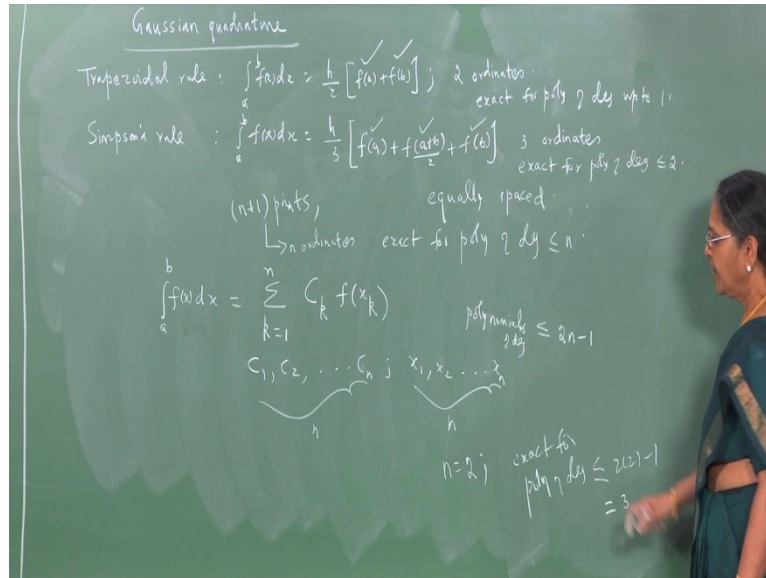

So you took two points and the method is exact for polynomials of degree upto 1. In the case of Simpson's rule it involves evaluation of function at three points. So three ordinates have to be obtained and the method is exact for polynomials of degree less than or equal to 2. In addition we know that these methods have been derived using equally spaced points.

And we observe that the Newton codes method which are derived with equally spaced points are such that if you are given information at n plus 1 points then you are able to obtain an integration method involving N ordinates and the method is exact for polynomials of degree less than or equal to n.

So one wanted to see can one derive an integration method such that the method is exact for polynomials of degree greater than n Gauss said that yes it is possible if one is ready to

sacrifice the requirement that the nodes must be equally spaced. So if you sacrifice the requirement there are nodes within that interval must be equally spaced it is possible for you to construct an integration method such that the method is exact for polynomials of degree greater than n.

(Refer Slide Time: 03:00)

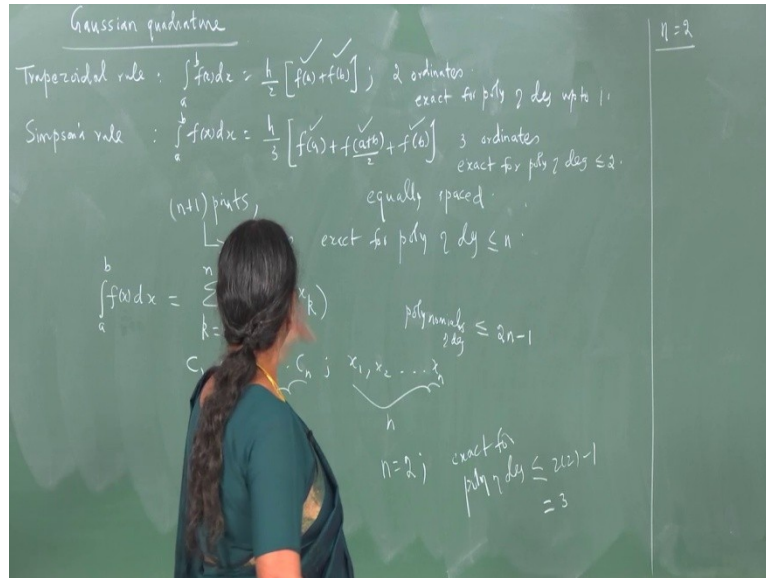

So he said that one can obtain integration methods of the form integral a to b f(x)dx which is of the form sigma say k is equal to 1 to n C k f (x k) so k runs from 1 to n. So there are n unknown constants C k which are C 1, C 2 etc C n. In addition we have x k which are also not known to us. So x 1 x 2 etc x k that is k running from 1 to n they are the nodes that we have to select in that interval a to b which need not be equally spaced so that we have another n unknowns.

So totally we have 2 n unknowns to be determined such that sigma k equal to 1 to n C k f(x k) will evaluate this integral and the method will be exact for polynomials of degree less than or equal to 2n minus 1. So how many ordinates that you use in this method there are only n ordinates. The ordinates are at x 1 x 2 etc x n. So you involve only information about the function at n nodes evaluation involves only n ordinates.

But the method that you derive is such that it is exact for polynomials of degree less than or equal to 2 n minus 1. Say for example if n is equal to 2 then you will derive a method which is exact for polynomials of degree less than or equal to 2 into 2 minus 1 namely less than or

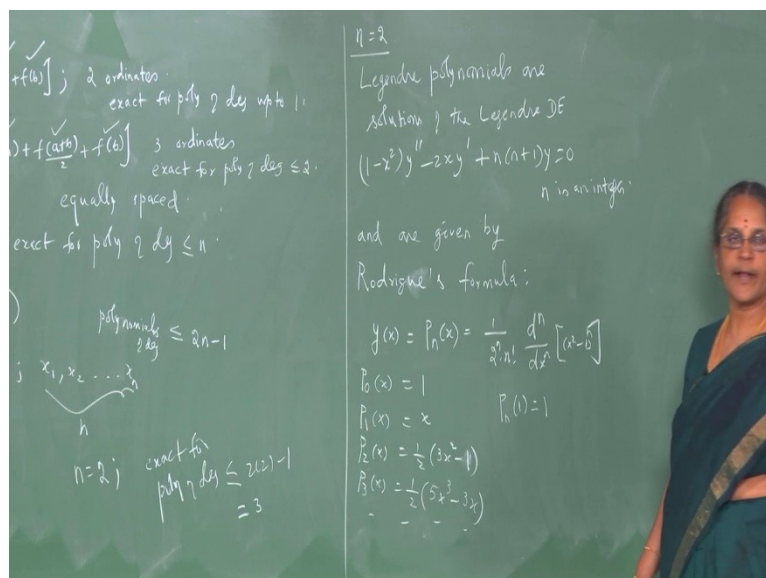

equal to 3. You will see that the x_i which are located here need not be equally spaced. So let us work out the details proposed by Gauss and arrive at a Gaussian Quadrature.

(Refer Slide Time: 05:40)

Say for the case when n is equal to 2. So we require an integral of the form $\int_a^b f(x) dx$ is $\int_a^b [C_1 f(x_1) + C_2 f(x_2)] dx$. You do not know C_1, C_2 you also do not know x_1, x_2 but the method must be exact for polynomials of degree less than or equal to $2n - 1$ namely less than or equal to 3. So this requires the knowledge of the properties of Legendre polynomials. So we briefly present those results and use them in the derivation of Gaussian Quadrature methods.

(Refer Slide Time: 06:30)

So what are Legendre polynomials? The Legendre polynomials are solutions of the Legendre equation Legendre differential equation which is $1 - x^2$ into $y'' - 2x$ into $y' + n(n + 1)$ into $y = 0$ where n is an integer. And solutions are given by Rodrigues formula you must have derived these in your course on differential equation when you studied about special functions.

So Rodrigues formula tells you that the solution of this equation $y(x)$ which is a Legendre polynomial of degree n when appears here in the differential equation in the form n into $n + 1$ then the solution is given by $1 - x^2$ power n into n factorial into n th derivative of $[x^2 - 1]$ to the power of n . So when n is 0 you get the Legendre polynomial of degree 0 which is 1 and then when n is 1 from here you will obtain that it is x $P_2(x)$ will be half of $(3x^2 - 1)$ and $P_3(x)$ will be half of $(5x^3 - 3x)$ and so on.

You can get higher degree polynomials and you observe that polynomials with suffix or odd polynomials odd degree polynomials and those denoted by even suffixes are even degree polynomials. In addition the polynomials have the property that $P_n(1)$ is equal to 1. You can check $P_2(1)$ is 2 by 2 $P_3(1)$ is again 1 and so on. So we satisfy the property that $P_n(1)$ is 1.

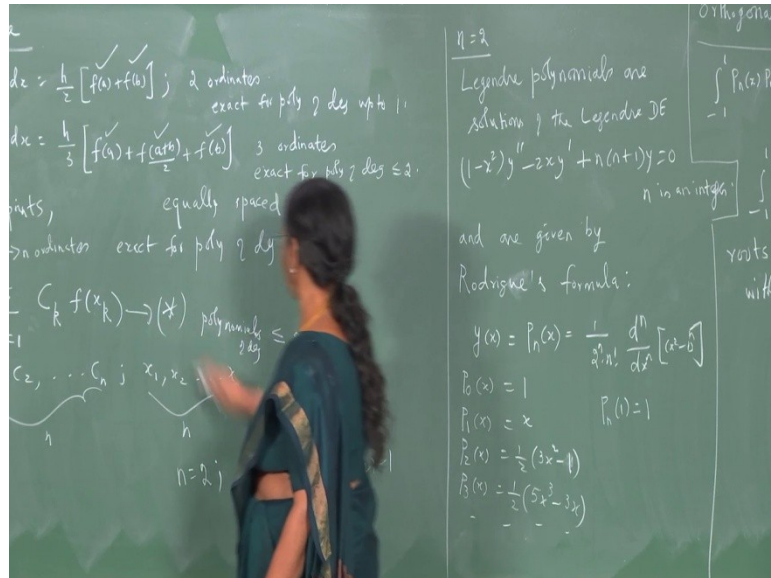

(Refer Slide Time: 09:20)

Further we satisfy an important property which is called Orthogonality Property which says $\int_{-1}^1 P_n(x) P_m(x) dx = 0$ whenever the polynomials are of different degree and it is $2/(2n + 1)$ when we have the same degree.

And these polynomials are such that if you consider $(-1, 1)$ $P_n(x)$ into x to the power of m dx that will be 0 where m is less than n . Further the roots of these polynomials or zeroes of these polynomials are the roots of $P_n(x)$ is equal to 0 like within the interval $(-1, 1)$.

(Refer Slide Time: 10:40)

So these are some properties which we require in deriving Gaussian Quadrature formulas. So we have recalled these results. So let us now work out the details of Gauss Quadrature method says when n is equal to 2 in this formula.

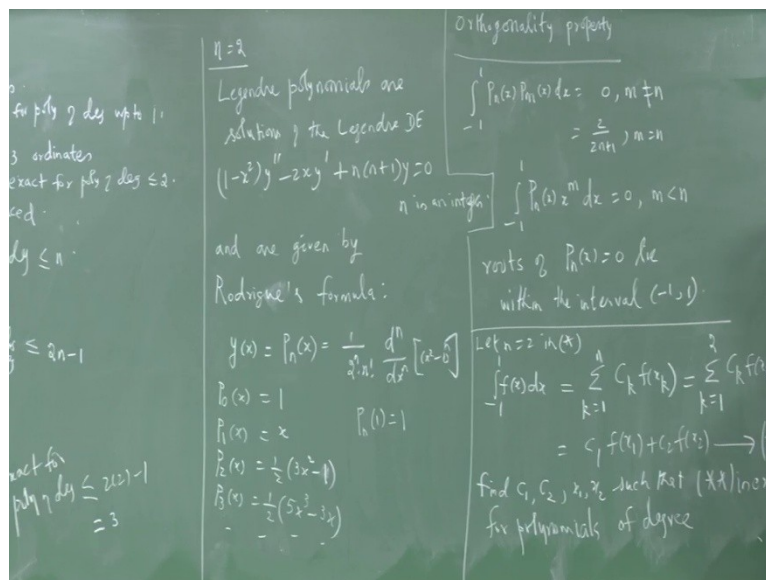

(Refer Slide Time: 11:07)

So let n be equal to 2 in star. So since I know that the Legendre polynomials are such that the roots of the Legendre polynomials $P_n(x)$ is equal to 0 lie within the interval (minus 1 to 1) Gaussian integration methods have been derived for integral minus 1 to 1 $f(x) dx$ so we seek an integration method such that integral minus 1 to 1 $f(x) dx$ is sigma k is equal to 1 to n $C_k f(x_k)$.

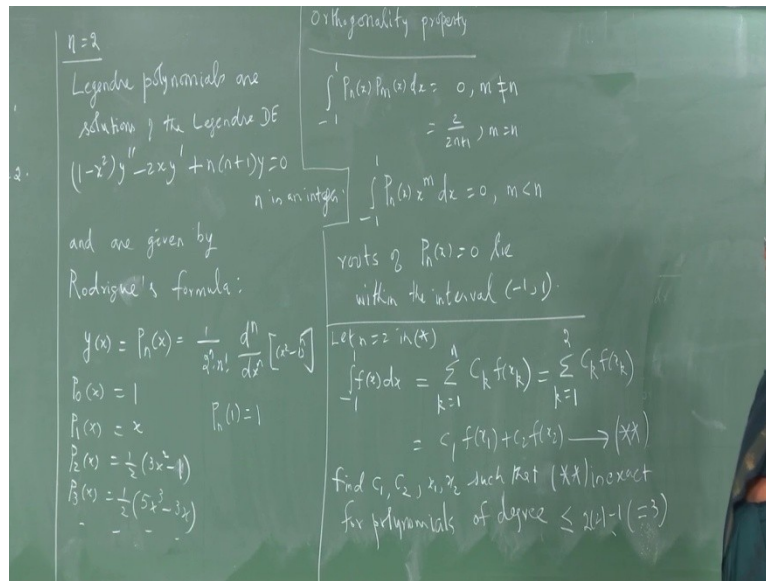

So you may ask me then how do you get if you are asked to evaluate an integral of the form integral a to b $f(x) dx$. We will illustrate it we simply have to use a transformation for change of variable such that the integral between a to b goes to integral between minus 1 to 1. So we shall discuss that later, let us now derive the integration method where n is equal to 2.

(Refer Slide Time: 12:30)

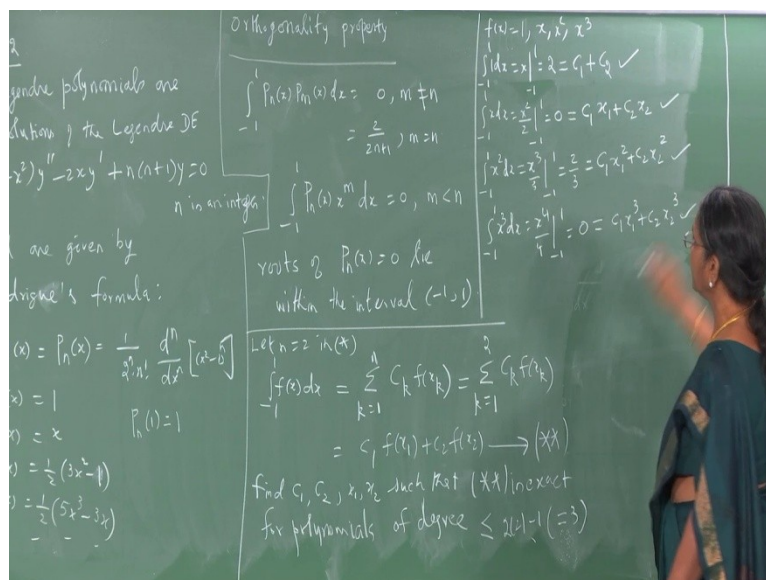

So we require a method such that integral minus 1 to 1 dx is sigma k equal to 1 to 2 $C_k f(x_k)$ so mainly C_1 into $f(x_1)$ plus C_2 into $f(x_2)$. So find C_1, C_2, x_1, x_2 such that this integration method let us call this as double star such that double star is exact for polynomials of degree n is 2 the method says for polynomials of degree less than or equal to $2n$ minus 1.

(Refer Slide Time: 13:26)

So here we determine these unknowns in such a way that the method is exact for polynomials of degree less than or equal to 2 into 2 minus 1 namely 3. So we know we have to work out the details.

(Refer Slide Time: 13:44)

So we take $f(x)$ to be equal to therefore 1, x , x square and x cube and substitute in double star and then see how you can make use of the properties of the Legendre polynomials and evaluate this integral so when I take $f(x)$ to be 1 then I get it is x between minus 1 and 1 so that is 2 and that will be equal to C_1 into $f(x_1)$ which is 1 plus C_2 which is $f(x_2)$.

Then integral minus 1 to 1 x dx is x square by 2 between minus 1 and 1 and that will be 0 and that will give you C 1 into f(x 1) is x 1 C 2 into f(x 2) is x 2. Then integral minus 1 to 1 x square dx will be x cube by 3 between minus 1 and 1 so that will give you 2 by 3 into C 1 into x 1 square plus C 2 into x 2 square. Then minus 1 to 1 x cube dx will be x to the power of 4 by 4 between minus 1 and 1 and that again will be 0 and that is equal to C 1 into x 1 cube plus C 2 into x 2 cube. So we observe that we have 4 equations to determine the four unknowns C 1 C 2 x 1 and X 2.

(Refer Slide Time: 15:50)

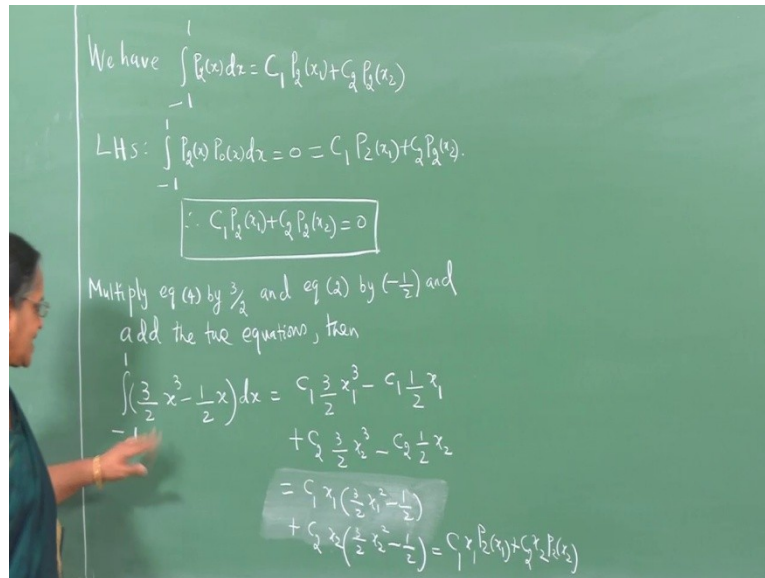

So at this stage we would like to bring in the knowledge of Legendre polynomials that we have and use their properties. So what I do is suppose I call these equations as 1 2 3 4 I shall multiply equation 3 by 3 by 2. So you will understand why we do is so multiply equation 3 by 3 by 2 and equation 1 by half and resulting equation 3 minus 1 gives the following.

So let us write minus 1 to 1 3 by 2 x square that is the left hand side then I have to subtract half times the first equation so integral minus 1 to 1 half so integration with respect to x. And what does that give that gives you from here I multiplied the equation 3 by 3 by 2.

So I have 3 by 2 into C 1 x 1 square plus 3 by 2 C 2 x 2 square and I subtract it half times the first equation, so half C 1 minus half C 2. So left hand side is minus 1 to 1 half of 3x square minus 1 dx and the right hand side gives me C 1 by 2 into 3 x 1 square minus so have taken these two terms, plus c 2 by 2 into 3 x 2 square minus 1.

So now it must be clear to you what is it that we have here? we have integral minus 1 to 1 $P_2(x) dx$ is equal to C_1 into what is half of $3x^2 - 1$ plus C_2 times again $P_2(x)$.

(Refer Slide Time: 18:39)

We have integral minus 1 to 1 $P_2(x) dx$ as $C_1 P_2(x)$ plus $C_2 P_2(x)$. The left hand side is integral minus 1 to 1 $P_2(x) dx$ which is $P_2(x)$ into $P_0(x) dx$ and that is 0 by Orthogonality property of Legendre polynomials. So this will be $C_1 P_2(x)$ plus $C_2 P_2(x)$ this gives therefore $C_1 P_2(x)$ plus $C_2 P_2(x)$ is 0. It is now derived another equation.

Suppose I multiply equation 4 by 3 by 2 and equation 2 by minus half and add the two equations then we get integral minus 1 to 1 $3x^3 - \frac{1}{2}x$ into dx is C_1 into $3x^3 - \frac{1}{2}x$ plus C_2 into $3x^3 - \frac{1}{2}x$ this gives C_1 into $x^4 - \frac{1}{2}x^2$ plus C_2 into $x^4 - \frac{1}{2}x^2$ square minus half which is $C_1 x^4 - \frac{1}{2}C_1 x^2$ plus $C_2 x^4 - \frac{1}{2}C_2 x^2$ that is $C_1 P_2(x)$ plus $C_2 P_2(x)$.

(Refer Slide Time: 21:46)

$$\int_{-1}^1 P_0(x) dx = C_1 P_1(x) + C_2 P_2(x)$$

$$\int_{-1}^1 P_0(x) dx = 0 = C_1 P_2(x) + C_2 P_1(x)$$

$$\therefore C_1 P_1(x) + C_2 P_2(x) = 0 \quad (5)$$

(4) by $\frac{3}{2}$ and eq (5) by $(-\frac{1}{2})$ and the two equations, then

$$\int_{-1}^1 \left(\frac{3}{2} x - \frac{1}{2} x \right) dx = C_1 \left(\frac{3}{2} x_1^3 - C_1 \frac{1}{2} x_1 \right) + C_2 \left(\frac{3}{2} x_2^3 - C_2 \frac{1}{2} x_2 \right)$$

$$= C_1 x_1 \left(\frac{3}{2} x_1^2 - \frac{1}{2} \right) + C_2 x_2 \left(\frac{3}{2} x_2^2 - \frac{1}{2} \right) = C_1 x_1 P_1(x_1) + C_2 x_2 P_2(x_2)$$

$$\text{LHS: } \int_{-1}^1 x \left[\frac{1}{2} \right] [3x^2 - 1] dx$$

$$= \int_{-1}^1 P_1(x) P_2(x) dx = 0$$

$$C_1 x_1 P_1(x_1) + C_2 x_2 P_2(x_2) = 0 \quad (6)$$

Now let us look at the left hand side so we have left hand side as integral minus 1 to 1 x into half of 3 x square minus 1 integrated with respect to x and that is integral minus 1 to 1 P 1(x) into P 2(x) dx which is again by the Orthogonality property of the Legendre polynomials 0. Next we have the second equation is to be given by C 1 into x 1 into P 2(x 1) plus C 2 into x 2 into P2(x 2) is 0. So let us call these equations as 5 and 6.

(Refer Slide Time: 22:56)

$$\int_{-1}^1 P_0(x) dx = C_1 P_1(x) + C_2 P_2(x)$$

$$\int_{-1}^1 P_0(x) dx = 0 = C_1 P_2(x) + C_2 P_1(x)$$

$$C_1 P_1(x) + C_2 P_2(x) = 0 \quad (5)$$

by $\frac{3}{2}$ and eq (5) by $(-\frac{1}{2})$ and the two equations, then

$$\int_{-1}^1 \left(\frac{3}{2} x - \frac{1}{2} x \right) dx = C_1 \left(\frac{3}{2} x_1^3 - C_1 \frac{1}{2} x_1 \right) + C_2 \left(\frac{3}{2} x_2^3 - C_2 \frac{1}{2} x_2 \right)$$

$$= C_1 x_1 \left(\frac{3}{2} x_1^2 - \frac{1}{2} \right) + C_2 x_2 \left(\frac{3}{2} x_2^2 - \frac{1}{2} \right) = C_1 x_1 P_1(x_1) + C_2 x_2 P_2(x_2)$$

$$\text{LHS: } \int_{-1}^1 x \left[\frac{1}{2} \right] [3x^2 - 1] dx$$

$$= \int_{-1}^1 P_1(x) P_2(x) dx = 0$$

$$C_1 x_1 P_1(x_1) + C_2 x_2 P_2(x_2) = 0 \quad (6)$$

\therefore for any arbitrary choice of C_1, C_2 , the eq (5) & (6) will be identically satisfied if x_1 & x_2 are chosen as zeros of P_2 , namely the roots of P_2

$$\frac{1}{2}(3x^2 - 1) = 0 \quad \frac{3x^2 - 1}{2} = 0$$

$$\Rightarrow x = \pm \frac{1}{\sqrt{3}}, x_1 = -\frac{1}{\sqrt{3}}, x_2 = \frac{1}{\sqrt{3}}$$

Now looking at equations 5 and 6 we observe that these two equations are identically satisfied for any choice of the constants C 1 and C 2. If we choose x 1 and x 2 to be the

zeroes of P_2 namely the Legendre polynomials of degree 2 in which case $P_2(x) = 0$ and therefore this equation will be identically satisfied and this will also be identically satisfied and for any arbitrary choice of C_1, C_2 equations 5 and 6 will be satisfied.

So therefore for any arbitrary choice of C_1 and C_2 the equations 5 and 6 will be identically satisfied if x_1 and x_2 are chosen as zeroes of P_2 namely the zeroes of half of $3x^2 - 1$ equal to 0. This is $P_2(x)$ so if I consider the roots of this equation which are zeroes of P_2 . Then they identically satisfy equation 5 and 6. So what are the zeroes they are given by x is equal to plus or minus 1 by root 3.

So we integrate between the limits minus 1 and 1 and the roots of $P_2(x)$ is equal to 0 are given by x_1 is equal to minus 1 by root 3 and x_2 is equal to plus 1 by root 3. So these two nodes lie in the interval minus 1 to 1 and they are located symmetrically about the origin and both these nodes are interior points they lie within the interval minus 1 to 1. So we have determined x_1 and x_2 the only problem that remains to be solved is determine the constants C_1 and C_2 .

(Refer Slide Time: 26:00)

So we consider the first two equations mainly $C_1 + C_2$ is equal to 2, $C_1 x_1 + C_2 x_2$ is equal to 0. These are the first two equations which we had written down. Now that I have determined x_1 and x_2 it is C_1 into (minus 1 by root 3) plus C_2 into (plus 1 by root 3) and that is 0 which shows that C_1 is equal to C_2 . So substitute here that will give you $C_1 = C_2$ so $C_1 = 1$ but $C_1 = C_2$ so $C_1 = C_2 = 1$.

And therefore we have the integration method to be given by integral minus 1 to 1 f(x) dx is equal to C 1 f(x 1) plus C 2 f(x 2) C 1 is 1 x 1 is minus (1 by root 3) C 2 is 1 and x 2 is plus 1 by root 3 so knowing the function f(x) which is the integrand in the given integral. You evaluate f(minus 1 by root 3) and at(plus 1 by root 3).

Then the sum of these values will give an approximation to this integral and the method is exact for polynomials of degree less than or equal to 2n minus 1 where n is 2 here mainly for polynomials of degree less than or equal to 3, so this method is exact for polynomials of degree less than or equal to 3. There are only two nodes at which the function is evaluated. The method is exact for polynomials of degree less than or equal to 3.

(Refer Slide Time: 28:15)

As we remarked earlier the two nodes lie within the interval and they are interior nodes and the method does not involve the function evaluation at the end points of the interval and therefore these methods are referred to as open type formulas which give you integration methods for evaluating a definite integral of the form minus 1 to 1 f(x)dx.

In Newton codes methods as we have discussed earlier for example the Trapezoidal rule Simpson's rule they both involved the ordinates of the function value at the end points of the interval they are referred to as closed type formulas whereas Gaussian Quadrature methods are open type formulas, since they do not involve function evaluation at the end points of the interval.

(Refer Slide Time: 29:20)

So we have derived two point Gaussian integration method given by this which requires the knowledge of roots of Legendre second degree polynomial so that once we know the function which has to be integrated between minus 1 and 1 evaluate this function at these two zeroes of P_2 or roots of equation $P_2(x) = 0$.

And that will immediately give you the value of this definite integral. So usually we will be given an integral of the form $\int_a^b f(x) dx$ and we will be asked to evaluate this integral. Suppose that we are asked to evaluate such an integral using Gaussian quadrature method namely use two point Gaussian Quadrature technique to evaluate this integral we observe that we have derived this method where an integral of the form $\int_{-1}^1 f(x) dx$ is expressed as $f(-1/\sqrt{3}) + f(1/\sqrt{3})$.

But the given problem involves limit as a and b where a and b need not be minus 1 and 1 respectively so we have to convert this integral $\int_a^b f(x) dx$ to an integral of the form $\int_{-1}^1 f(x) dx$. So we consider the transformation which converts integral between a and b and integral between minus 1 and 1. So let us see how we can do this.

(Refer Slide Time: 31:10)

So let us consider integral a to b $f(x) dx$, so I would like to convert this integral to the form integral minus 1 to 1 say $f(x)dx$ and then evaluate it using Gaussian Quadrature so we make use of this transformation x is b minus a by 2 into x plus b plus a by 2. Let us see whether it works. So when x takes the lower limit value a then we have a equal to b minus a by 2 into x plus b plus a by 2. So we have a minus b plus a by 2 is b minus a by 2 into x .

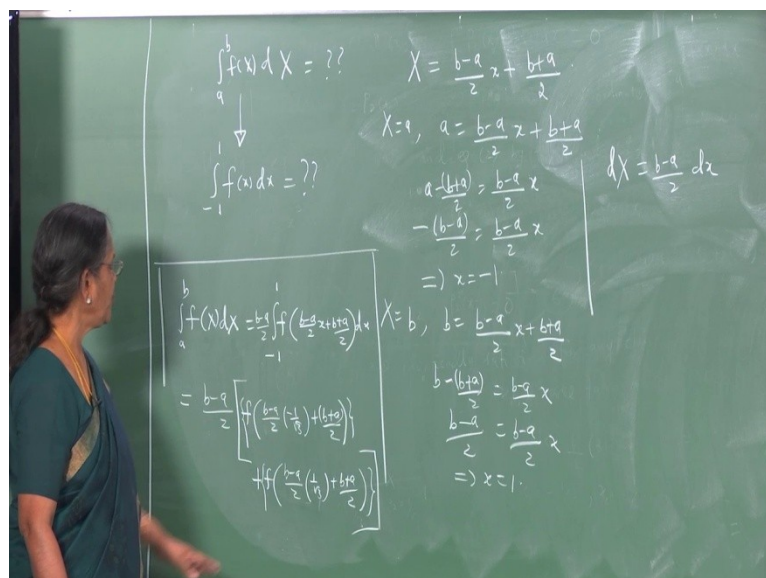

So we have a minus a by 2 minus b by 2 which is minus of b minus a by 2 and that is minus b minus a by 2 into x which tells that x takes the value minus 1. So when capital x is a small x takes the value minus 1. What happens when x takes the value b that gives you b minus b plus a by 2 is b minus a by 2 into x . So b minus b by 2 is b by 2 minus a by 2 that is the left hand side and the right hand side is b minus a by 2 into x . So that shows that x takes the value 1. So therefore when capital x varies between a and b small x varies between minus 1 and 1.

(Refer Slide Time: 33:25)

And therefore this integral, integral a to b f(x) dx will be equal to under this transformation minus 1 to 1 f of what is capital X, capital X is (b minus a by 2 into small x plus b plus a by 2 and what is b capital X, b capital X from here is b minus a by 2 into dx. So b minus a by 2 into dx. So if I have integral a to b f(X) dx b minus a by 2 integral minus 1 to 1 f evaluated at this node, into dx. So suppose I apply Gaussian Quadrature with n is equal to 2 and evaluate this integral what is it b minus a by 2 into minus 1 to 1 f of this integration with respect to x.

(Refer Slide Time: 34:39)

So that gives you, you should take the node at minus 1 by root 3. So at x is equal to minus 1 by root 3 the function must be evaluated. So that gives you this function evaluated at b minus a by 2 into minus $[(1 \text{ by root } 3) \text{ plus } b \text{ plus } a \text{ by } 2]$ that is the first term and then the next term will be $f(\text{evaluated at } 1 \text{ by root } 3 \text{ so } b \text{ minus } a \text{ by } 2 \text{ into } (1 \text{ by root } 3) \text{ plus } b \text{ plus } a \text{ by } 2)$ that is going to be the second term. So this integral has been evaluated using Gaussian Quadrature you know a b etc because the upper and the lower limits are known and therefore substitute those values and this will give you the value of this integral between a and b .

So let us take example and illustrate this.

(Refer Slide Time: 35:50)

Evaluate integral minus 1 to 1 or let us do for a general integral of the form a to b so integral 2 to 3 $\cos 2X$ by $1 + \sin X$ integration with respect to x using Gauss quadrature method then is equal to 2. So we call this as Gauss two point Quadrature formula. So evaluate this integral using Gauss two point integration method. So we write down the transformation X is b minus a so a is 2 b is 3 so b minus a so 1 by 2 into x plus b plus a so 2 plus 3 so 5 by 2. So this is the transformation and dX is half dx .

(Refer Slide Time: 37:07)

$$\int_2^3 \frac{\cos 2X}{1 + \sin X} dX, \quad X = \frac{1}{2}x + \frac{5}{2}$$

$$dX = \frac{1}{2}dx$$

$$a = 2, \quad b = 3$$

$$\int_2^3 \frac{\cos 2X}{1 + \sin X} dX = \frac{1}{2} \int_{-1}^1 \frac{\cos 2\left(\frac{x}{2} + \frac{5}{2}\right)}{1 + \sin\left(\frac{x}{2} + \frac{5}{2}\right)} dx = \frac{1}{2} \left[\frac{\cos\left(\frac{-1}{2\sqrt{3}} + \frac{5}{2}\right)}{1 + \sin\left(\frac{-1}{2\sqrt{3}} + \frac{5}{2}\right)} + \frac{\cos\left(\frac{1}{2\sqrt{3}} + \frac{5}{2}\right)}{1 + \sin\left(\frac{1}{2\sqrt{3}} + \frac{5}{2}\right)} \right]$$

$$= \frac{1}{2} [0.56558356 - 0.15856672]$$

$$= 0.20350842$$

$\int_{-1}^1 f(x) dx = f\left(\frac{-1}{\sqrt{3}}\right) + f\left(\frac{1}{\sqrt{3}}\right)$
is exact for poly of deg ≤ 3 .

So by that formula integral 2 to 3 cos 2X by 1 plus sin X dx will be integral minus 1 to 1 f (cos 2 what is x (x by 2 plus 5 by 2) divided by 1 plus sin (x by 2 plus 5 by 2) into dX that is half of dx. So now we would like to evaluate this using two point integration method so what does it say? It simply says get the function value at my x is equal to minus 1 by 3.

So the integral give you half of cos (x which is minus 1 by root 3) divided by 1 plus sin (x is equal to minus 1 by root 3). So (minus 1 y 2 root 3) plus 5 by 2. So we have evaluated f(minus 1 by root 3) then the second term at x is equal to 1 by root 3 this should be evaluated so cos (x 1 by root 3 plus 5 by 2) divided by 1 plus sin (1 by root 3 plus 5 by 2).

So both the ordinates have been computed and this gives you the value of the integral. So you can use your calculator and then show that it is equal to half of 0.56558356 minus 0.15856672 and when you simplify you get the result 0.2350842. So using 2 point integration method we have been able to evaluate this integral.

(Refer Slide Time: 39:46)

Let us take another example so evaluate integral 0 to 1 $f(x)dx$ where $f(x)$ is 1 by 1 plus x. So the interval a to b is now 0 to 1. So I have to make a transformation so that this integral is converted to an integral of the form minus 1 to 1 in order that I am able to apply Gauss 2 point integration method.

So I make the transformation x is equal to b minus a by 2 into t plus b plus a by 2 that is 1 minus 0 by 2 is 0 plus 1 plus 0 by 2 so it is t by 2 plus half. So that dx is half dt. So what is the value of this integral it is half integral minus 1 to 1 right? dx is half dt divided by 1 plus what is x t by 2 plus half. So it is half of integral minus 1 to 1 dt by 3 by 2 plus t by 2.

(Refer Slide Time: 41:10)

So what is my function , my function here is f(t) and that is 1 by 3 by 2 or 3 plus t by 2 or 2 by 3 plus t that is my f(t). So this integral if I call this say as i then integral i will be half of f evaluated at minus (1 by root 3) plus f evaluated at plus (1 by root 3) that is Gauss 2 point method so that will give you half of we know what the function is 2 by 3 plus t is minus 1 by root 3 plus 2 by 3 plus t is plus 1 by root 3].

So simplify this and write down what is the value of the integrals. So the natural interest is to see what happens if you increase this n namely immediate curiosity is to see what is going to be Gauss 3point integration Quadrature method so we shall derive Gauss 3 point integration method in the next lecture. Thank You!
