(Refer Slide Time: 0:38)

Good morning everyone, in the last class we discussed power method for computing numerically the largest eigenvalue in magnitude of a given matrix A. So let us illustrate this method by taking some examples. So we said that, if we are given a square matrix, say N cross N matrix, we start with an initial vector which we call as  $V_0$  and we find the vectors say  $Y_{k+1}$  which are  $AV_k$ . And the next vector  $V_{k+1}$  will be  $Y_{k+1}$  by  $M_{k+1}$  where  $M_{k+1}$  is the largest element in magnitude in  $Y_{k+1}$  vector. Then  $\lambda_1$  will be limit as  $T$  tending to infinity of the  $m$ th components of vector  $Y_{k+1}$  by the  $m$ th component of the vector  $V_k$ .

(Refer Slide Time: 2:27)

$$A = \begin{pmatrix} 3 & -5 \\ -2 & 4 \end{pmatrix}, \vec{v}_0 = \begin{pmatrix} 1 \\ 1 \end{pmatrix}$$

$$\vec{y}_1 = A\vec{v}_0 = \begin{pmatrix} 3 & -5 \\ -2 & 4 \end{pmatrix} \begin{pmatrix} 1 \\ 1 \end{pmatrix} = \begin{pmatrix} -2 \\ 2 \end{pmatrix} = -2 \begin{pmatrix} 1 \\ -1 \end{pmatrix}$$

$$\vec{v}_1 = \frac{\vec{y}_1}{-2} = \begin{pmatrix} 1 \\ -1 \end{pmatrix}$$

$$\vec{y}_2 = A\vec{v}_1 = \begin{pmatrix} 3 & -5 \\ -2 & 4 \end{pmatrix} \begin{pmatrix} 1 \\ -1 \end{pmatrix} = \begin{pmatrix} 8 \\ -6 \end{pmatrix} = 8 \begin{pmatrix} 1 \\ -0.75 \end{pmatrix} = 8\vec{v}_2$$

$$\vec{y}_3 = A\vec{v}_2 = \begin{pmatrix} 3 & -5 \\ -2 & 4 \end{pmatrix} \begin{pmatrix} 1 \\ -0.75 \end{pmatrix} = \begin{pmatrix} 6.75 \\ -5 \end{pmatrix} = 6.75 \begin{pmatrix} 1 \\ -0.7407 \end{pmatrix} = 6.75\vec{v}_3$$

$$\vec{y}_4 = A\vec{v}_3 = \begin{pmatrix} 3 & -5 \\ -2 & 4 \end{pmatrix} \begin{pmatrix} 1 \\ -0.7407 \end{pmatrix} = \begin{pmatrix} 6.7035 \\ -4.9628 \end{pmatrix} = 6.7035 \begin{pmatrix} 1 \\ -0.7403 \end{pmatrix} = 6.7035\vec{v}_4$$

$$\vec{y}_5 = A\vec{v}_4 = \begin{pmatrix} 3 & -5 \\ -2 & 4 \end{pmatrix} \begin{pmatrix} 1 \\ -0.7403 \end{pmatrix} = \begin{pmatrix} 6.7015 \\ -4.9612 \end{pmatrix} = 6.7015 \begin{pmatrix} 1 \\ -0.7403 \end{pmatrix} = 6.7015\vec{v}_5$$

$$\vec{y}_6 = A\vec{v}_5 = \begin{pmatrix} 3 & -5 \\ -2 & 4 \end{pmatrix} \begin{pmatrix} 1 \\ -0.7403 \end{pmatrix} = \begin{pmatrix} 6.7015 \\ -4.9612 \end{pmatrix} = 6.7015 \begin{pmatrix} 1 \\ -0.7403 \end{pmatrix} = 6.7015\vec{v}_6$$

∴ convergence has occurred.  
 $\lambda_1 = 6.7015$   
 Corresponding eigenvector is  $\begin{pmatrix} 1 \\ -0.7403 \end{pmatrix}$

And the vector VK +1 that we have obtained will give us the required eigenvector. So let us now illustrate this procedure which is power method for computing numerically the largest eigenvalue of a given matrix A. So let us consider the given matrix A to be a 2 cross 2 matrix having entries 3, -5 and -2, 4. We start with an initial vector V0, say 1, 1. So we should find 1<sup>st</sup> vector Y1, which is A times V0, so it is 3, -5, -2, 4 into 1, 1 and that is the column vector having components -2, 2. Now I remove the largest element in magnitude and write down the vector as -2 times 1, -1. So now I should define V1, what is V1, that is Y1 - the largest value of the element that I have factored out.

So that will give you 1, -1, so with this V1 I compute Y2 vector which is A V1. 3, -5, -2, 4 into V1 which is 1, -1 and that is 8, -6, I remove the element which has largest magnitude and write down the vector as 1, -0.75. So it is 8 times vector V2. So we compute Y3 which is A V2, 3, -5, -2, 4 into V2 which is 1, -0.75. That turns out to be 6.75, -5, so I remove 6.75 and the vector that I get is 1, -0.7407, so it is 6.75 times vector V3. We compute Y4 which is A V3, so 3, -5, -2, 4 into V3 which is 1, -0.7407 and that turns out to be 6.7035, -4.9628, so we remove 6.7035 and the vector is 1, -0.7403. So we have Y4 to be 6.7035 times vector V4. We continue this process and compute what is Y5 and that is A V4.

So 3, -5, -2, 4 into vector V 4 is 1, -0.7403 and that turns out to be 6.7015 - 4.9612, so I remove 6.7015 and we get 1, -0.7403. So we have 6.7015 times vector V5 and we see that every time we perform the computations, the vector is such that the components in the vector are coming to be closer to each other. So let us perform another iteration and see. So compute Y6, so vector Y6 will be A into vector V5, so 3, -5, -2, 4 into V5 which is 1, -0.7403 and that

turns out to be 6.7015, -4.9612, so it is 6.7015 into 1, -0.7403. And so this will be 6.7015 into vector V6.

So at this stage we observe that 6.7015 into vector V5 is the same as 6.7015 into vector V6 and therefore convergence has occurred and therefore we can stop our computations and write down what the eigenvalue is and the corresponding eigenvectors. So we observe that the eigenvalue lambda 1 which is numerically the largest eigenvalue of this matrix is 6.7015. And what is the eigenvector, the corresponding eigenvector is given by 1, -0.7403. So power method helps us to compute numerically the largest eigenvalue or the most dominant eigenvalue of a given matrix A numerically. And the procedure is illustrated by means of this example.

(Refer Slide Time: 9:39)

So let us now take a 3 by 3 matrix A and then work out the details, so the problem is find the largest eigenvalue in modulus and the corresponding eigenvector of the matrix A, which has elements -15, 4, 3, 10, -12, 6, 20, -4, 2 and we are asked to obtain the dominant eigenvalue of this matrix by power method numerically. So we start with the initial vector  $\bar{V}$  having components 1, 1, 1, I compute the vector  $Y_1$  1<sup>st</sup>. What is it, it is equal to  $A \cdot \bar{V}$ , so A into vector 1, 1, 1 where A is this matrix. The entries in the product of these 2 matrices are given by -8, 4, 18. So I have to define now my vector  $V_1$  which is vector  $Y_1$  by the largest element in the vector  $Y_1$ .

So that will give me -8 by 18, 4 by 18, 1 and that is -4 by 9, 2 by 9, 1. Now that I know the vector  $V_1$ , I compute  $Y_2$ , which is  $AV_1$ . So I need to -4 by 9, 2 by 9, 1 and that turns out to be the vector 95 by 9, -10 by 9, -70 by 9. And I divide by the largest element, namely 95 by 9, so if I remove that factor, I get a new vector which is  $V_2$ . So  $V_2$  turns out to be the vector 1, -2 by 9, -14 by 9. So we compute  $Y_3$ ,  $Y_4$  and so on, so I leave these computations for you. And when it comes to obtaining the vector  $Y_7$ , it turns out to be the vector -19.8674, 9.7072 and 19.8524 and therefore I compute vector  $V_7$  by dividing vector  $Y_7$  by the numerically largest element in that vector.

That gives me  $V_7$  to be -1.0, 0.4886, 0.9992. So we compute  $Y_8$  which is  $A \cdot V_7$  and that gives 19.952, -9.868, -19.956. And so I compute vector  $V_8$  which is  $Y_8$  vector by numerically the largest element in  $Y_8$ . And that turns out to be 0.9998, -0.494 and -1. And so we work out  $Y_9$  which is  $A \cdot V_8$  and this turns out to be 19.973, 9.926 and 19.988. Suppose say the problem also says perform 9 steps using power method and write down the numerically largest eigenvalue of matrix A.

So we have performed 9 steps and at this stage we want to stop our computations because we are asked to do only 9 steps of computations of power method. And so we determine the eigenvalue and the Eigen vector. So what is going to be an approximation to the largest eigenvalue in modulus? So it is modulus of lambda and that will be the Mth component of vector  $Y_9$  by the Mth component of vector  $V_8$ . So I have to compute the ratio of the 1<sup>st</sup> component of  $Y_9$  and 1<sup>st</sup> component of  $V_8$ . Then take the 2<sup>nd</sup> component of  $Y_9$  by the 2<sup>nd</sup> component of  $V_8$  and then get the ratio, the 3<sup>rd</sup> component of  $Y_9$  and the 3<sup>rd</sup> component of  $V_8$  and obtain what the value is.

So we get, for the 1<sup>st</sup> component of  $Y_9$  is 19.973 divided by 1<sup>st</sup> component of  $V_8$  is 0.9998, the 2<sup>nd</sup> component of  $Y_9$  is 9.926 and that of  $V_8$  is -0.494, the 3<sup>rd</sup> component is 19.988

divided by -1. I observe that if I compute these ratios and take the absolute value, then round it off to 3 digits, then I end up with mod lambda to be 20. So if I compute this ratio, it is going to be very close to 19.966 etc, similarly this one and here it is going to be -19.988, I observe that that is the largest, so in absolute value correct to 3 digits and I round it off to 3 digits, mod lambda is close to 20 and therefore that is the largest eigenvalue in magnitude of this matrix A.

So we have to get the corresponding eigenvector, so the corresponding eigenvector is going to be the vector having the vector having components namely V8, that will give you 0.9998, -0.494 and -1. So the numerically largest eigenvalue and the corresponding eigenvector of the given matrix A have been computed using power method. I will give you some problems, you can try to work about that home and I will include some more problems in the assignment sheet.

So find numerically the largest eigenvalue of the matrix  $\begin{bmatrix} 1 & -3 & 2 \\ 2 & 4 & 4 \\ -1 & 6 & 3 \end{bmatrix}$  by power method. You start with the vector V0 having components 1, 1, 1, I will give you the final answer, you can try to see, compute 16 steps of computations, I am sure that at the 16<sup>th</sup> step you will get Y 16 to be 6.9998 into 0.3000, 0.06661 and therefore eigenvalue, the numerically largest eigenvalue is close to 7. So using power method we have been able to compute the most dominant eigenvalue. The question now is, is it possible to obtain the smallest eigenvalue of this matrix A using power method.

(Refer Slide Time: 19:22)

The answer is yes and let us see how we can obtain the smallest eigenvalue. So suppose that we assume that the matrix  $A$  has largest eigenvalue say  $\lambda$ . Then what does that mean, it means  $AX$  is equal to  $\lambda X$  and let us assume that  $A$  is invertible. Then when I pre multiply this by  $A$  inverse, then I get  $IX$  to be equal to  $A$  inverse into  $X$  multiplied by  $\lambda$ . Therefore  $1$  by  $\lambda X$  will be equal to  $A$  inverse  $X$ . So when we say that  $AX$  is equal to  $\lambda X$ , we say that  $\lambda$  is an eigenvalue of the matrix  $A$  and the corresponding eigenvector is  $X$ . Now this statement tells us that  $1/\lambda$  is an eigenvalue of  $A$  inverse and the corresponding eigenvector is the same vector  $X$  for the eigenvalue  $\lambda$  of the matrix  $A$ .

So this tells you that  $1/\lambda$  is an eigenvalue of matrix  $A$  inverse with the same eigenvector  $X$ . If I call the dominant eigenvalue of  $A$  inverse as  $\mu$ , so that  $A$  inverse  $X$  is equal to  $\mu X$ , then it is clear that  $1/\mu$  is the least eigenvalue of the matrix  $A$ . Why, what have we shown? If  $\lambda$  is the dominant eigenvalue of matrix  $A$ , then  $A$  inverse  $X$  is  $1/\lambda$  into  $X$ , so that if  $\mu$  is the dominant eigenvalue of  $A$  inverse, such that  $A$  inverse  $X$  is equal to  $\mu X$ , then  $1/\mu$  will be the least eigenvalue of the matrix  $A$ . So if I ask you to compute the smallest eigenvalue of a given matrix  $A$ , what is it that you should do?

Given the matrix  $A$ , compute its inverse, say by Gauss Jordan method and then compute its dominant eigenvalue using power method, take the reciprocal, that gives you the least eigenvalue of the given matrix  $A$ . And therefore it is possible for you to compute the smallest eigenvalue in magnitude for the given matrix  $A$ . So let us work out an example illustrating this.

(Refer Slide Time: 23:19)

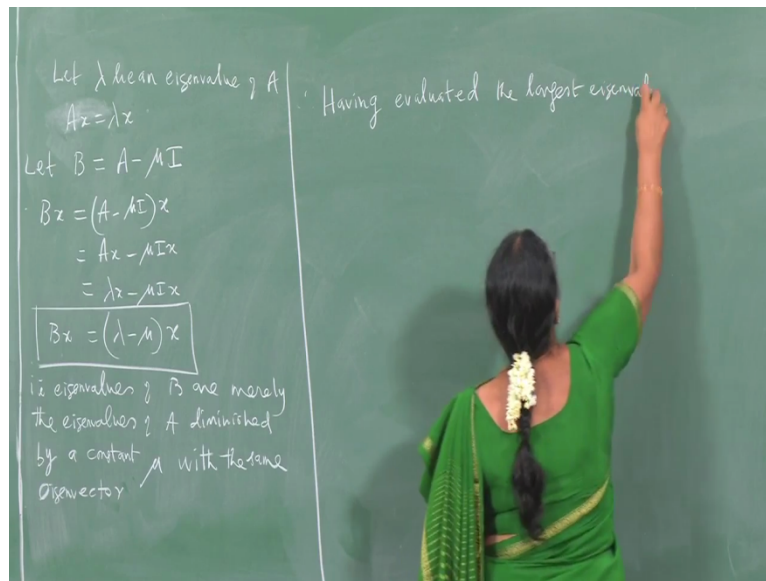

So if I consider matrix A to be given by -15, 4, 3, 10, -12, 6, 20, -4, 2 and I am asked to compute the smallest eigenvalue of this matrix A. So I immediately compute the inverse of the matrix A and it turns out to be 0, -0.02, 0.06, 0.1, -0.09, 0.12, 0.2, 0.02, 0.14. So I have to now compute the most dominant eigenvalue of this matrix A inverse. So use power method to compute the most dominant eigenvalue. Start with the vector say  $V_0$  which is 1, 1, 1 and compute  $Y_1$  which is A inverse into  $V_0$  because you are computing the dominant eigenvalue of the matrix A inverse.

So your  $Y_1$  is A inverse into  $V_0$ . So continue your computations and show that the dominant eigenvalue of A inverse turns out to be say 0.2, that is 1 by 5. Show that the dominant eigenvalue of A inverse is 1 by 5 and therefore the least eigenvalue or the smallest eigenvalue in magnitude for the given matrix A is going to be 5. So given a matrix A, you know how to get the largest eigenvalue by power method and how to get the least eigenvalue by computing the dominant eigenvalue of A inverse and taking its reciprocal and that will give you the smallest eigenvalue of A.

So you now know using power method how to compute both the largest eigenvalue and the least eigenvalue. There is also another of computing the smallest eigenvalue of a given matrix A even without computing what A inverse is. So let us see how this can be done.

(Refer Slide Time: 26:08)

So let  $\lambda$  be an eigenvalue of  $A$ , so  $A$  is a given matrix, suppose  $\lambda$  is an eigenvalue of  $A$ , that  $Ax$  is equal to  $\lambda x$ . Let us find a matrix  $B$  where  $B$  is given by  $A - \mu I$ ,  $\mu$  is some constant. Then let us compute what is  $Bx$ , so  $Bx$  is  $A - \mu I$  into  $x$ . So it is  $Ax - \mu Ix$ , but what is  $Ax$ ,  $Ax$  is  $\lambda x$ . So this tells you it is  $\lambda - \mu$  into  $x$ . So what have we shown, matrix  $B$  which is  $A - \mu I$  is such that it satisfies this equation namely  $Bx$  equal to  $(\lambda - \mu)x$ . What are  $\lambda$ 's,  $\lambda$ 's are eigenvalues of given matrix  $A$ .

And therefore  $A - \mu I$  has eigenvalues  $\lambda - \mu$ . And therefore the eigenvalues of  $B$  are nearly the eigenvalues of  $A$  diminished by a constant  $\mu$ . And what about the eigenvector, the eigenvector is the same, namely if  $\lambda$  is an eigenvalue of  $A$  and the corresponding eigenvector is  $x$ , then  $\lambda - \mu$  is an eigenvalue of  $B$  having the same eigenvector  $x$ . So that is what we want to write, the eigenvalues of  $B$  are nearly eigenvalues of  $A$  diminished by a constant  $\mu$  with the same eigenvector.

(Refer Slide Time: 29:06)

So therefore if you evaluate the largest eigenvalue of  $A$  and call it as  $\lambda_1$ , then we can determine the smallest eigenvalue of  $A$  by modifying the matrix. We are given a matrix  $A$ , we would now like to consider another matrix which is different from  $A$ , so we want to do some modification in the matrix  $A$ , what is it? Take it in the form  $A - \lambda_1 I$ , take the matrix  $A$  and subtract the matrix which is  $\lambda_1$  times the identity matrix. By what we have discussed, what can you say about the Eigen values of this matrix, this matrix has eigenvalues given by say  $\lambda'_p$  which is equal to  $\lambda_p - \lambda_1$  for  $p$  is equal to 1, 2, 3 up to  $N$  where what are  $\lambda_p$ 's?  $\lambda_p$ 's are eigenvalues of  $A$ .

Now I want  $\lambda_p$  to be the smallest. So for  $\lambda_p$  to be the smallest,  $\lambda'_p$  must be the largest in magnitude eigenvalue of which matrix,  $A - \lambda_1 I$ . What are  $\lambda_p$ 's, they are the eigenvalues of the given matrix  $A$ . So  $\lambda_p - \lambda_1$  for  $p$  taking values 1, 2, 3 up to  $N$  and if you call that as  $\lambda'_p$ , then the  $\lambda'_p$  are such that they are the eigenvalues of  $A - \lambda_1 I$ . So in order that you are  $\lambda_p$  which is an eigenvalue of  $A$  to be the smallest, you must have  $\lambda'_p$  to be the largest eigenvalue in magnitude of  $A - \lambda_1 I$ .

Can you compute this, yes, we know we can use power method to obtain the largest or the dominant eigenvalue in magnitude of a given matrix. What is the matrix that is given to you now, the given matrix is say  $B$  which is  $A - \lambda_1 I$ . Do you know  $\lambda_1$ , yes, it is the dominant eigenvalue of the given matrix  $A$ . So compute a new matrix, call it is  $B$  which is  $A - \lambda_1 I$  and compute its dominant eigenvalue, so you are using again power method to compute its dominant eigenvalue. Then once you know it is the dominant

eigenvalue of  $A - \lambda_1 I$ , then your that eigenvalue +  $\lambda_1$  will give you  $\lambda_p$  which is the least eigenvalue.

(Refer Slide Time: 33:05)

So let us discuss about the corresponding eigenvector. So if suppose I call  $x_p$  as the corresponding eigenvector, then  $(A - \lambda_1 I)x_p$  must be  $(\lambda_p - \lambda_1)x_p$  because  $\lambda_p - \lambda_1$  are eigenvalues of  $A - \lambda_1 I$  and the corresponding eigenvector is  $x_p$ . So what does this give, this gives you  $Ax_p$  is equal to  $\lambda_p x_p$ . While the next, the next term will be  $-\lambda_1 I x_p$  that will cancel with  $-\lambda_1 x_p$ . So we get  $Ax_p = \lambda_p x_p$ .

What does that give, this gives you that the Eigen vector corresponding to the eigenvalue  $\lambda_p$  which is the smallest eigenvalue of  $A$  is the same as the corresponding eigenvector associated with the eigenvalue  $\lambda_p - \lambda_1$  of the matrix  $A - \lambda_1 I$ . So you not only get the smallest eigenvalue in magnitude of the given matrix  $A$  but you also get the corresponding eigenvector, what is it, it is a  $x_p$ , what is this eigenvector, this is the eigenvector which is associated with the eigenvalue  $\lambda_p - \lambda_1$  of the matrix  $A - \lambda_1 I$ .

So you are able to get the smallest eigenvalue as well as the largest eigenvalue by using the power method. So let us just recall the steps for computing the smallest eigenvalue of a given matrix  $A$ . So you start with the matrix  $A$ , get its largest eigenvalue, call that as  $\lambda_1$ , so it is the largest eigenvalue in magnitude for the matrix  $A$ , call that as  $\lambda_1$ . Now form a

matrix  $B$  which is  $A - \lambda I$ , for this matrix, you compute the largest eigenvalue, then the smallest eigenvalue of the given matrix  $A$  will be  $\lambda$  such that if  $\lambda$  is the dominant eigenvalue of  $A - \lambda I$ , then  $\lambda$  is related by  $\lambda$  is  $\lambda - \lambda$ .

So you immediately know what is the smallest eigenvalue of the given matrix, what is the associated eigenvector. You compute the corresponding eigenvector associated with  $\lambda$  for the matrix  $A - \lambda I$ , that Eigen vector is the Eigen vector associated with the smallest eigenvalue  $\lambda$  of the matrix  $A$ . So that completes our discussion on how we can get the smallest eigenvalue. So the method does not involve computation of inverse of the matrix  $A$ , so it is much easier to work out because you again apply power method to a new matrix and therefore the computations are very simple.

Can we give locations of the eigenvalues for a given matrix  $A$ ? The answer is yes, there are results which clearly specify the regions within which circular disks within which the eigenvalues are located. So we look into these results and therefore we will be able to know where the eigenvalues of a given matrix are located. The following result gives us a way to find the location of eigenvalues of a given matrix  $A$ . What does the result say, it says that the largest eigenvalue in modulus of a square matrix  $A$  cannot exceed the largest sum of the moduli of the elements along any row or any column.

(Refer Slide Time: 38:23)

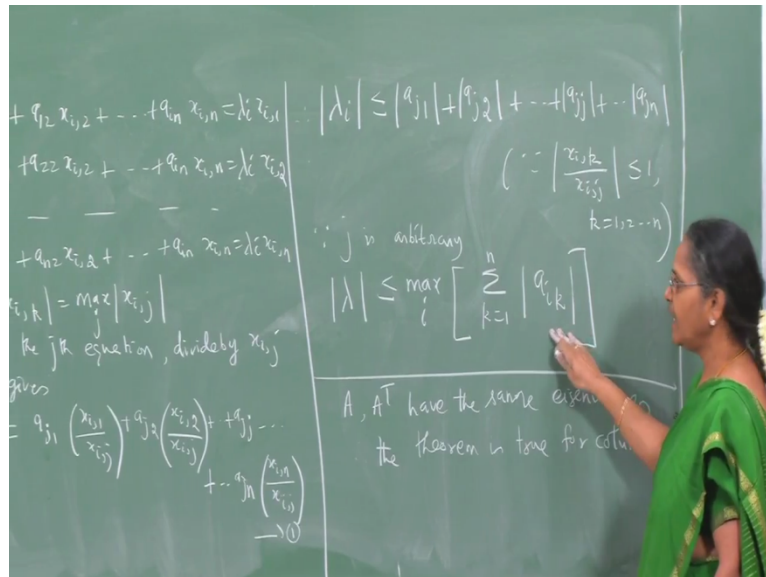

Suppose say  $\lambda_i$  is an eigenvalue of an  $N$  cross  $N$  matrix  $A$ , let us take  $A$  has entries denoted by  $A_{ij}$  where  $i$  and  $j$  run from  $1$  to  $N$ . Suppose  $X_i$  the corresponding eigenvector and having components  $X_{i1}, X_{i2}, \dots, X_{iN}$ , then we know that  $AX_i = \lambda_i X_i$ . So if I write out these  $N$  equations, then they are of this form.  $A_{i1} X_{i1} + A_{i2} X_{i2} + \dots + A_{iN} X_{iN} = \lambda_i X_{i1}$ . Similarly I take the  $2^{\text{nd}}$  row of  $A$  and multiply this column vector and equate that to the  $2^{\text{nd}}$  entry in  $\lambda_i X_i$ . So I continue and write down the  $N$ th equation. Now I take modulus of  $X_{i1}$  to be the maximum of modulus of  $X_{ij}$  over  $j$ .

So what does, once I get that, I take the  $j$ th equation and divide the  $j$ th equation by  $X_{ij}$ . So what will I get, I will get  $\lambda_i$ , so if I take the  $2^{\text{nd}}$  equation and divide by  $X_{i2}$ , then on the right-hand side I have just  $\lambda_i$ . So here I select the  $j$ th equation and divide the  $j$ th

equation by  $x_{ij}$ . So that will give you  $\lambda_i$  is equal to  $A_{j1}$ , that will be the 1<sup>st</sup> term here,  $A_{j1} x_{i1}$ , that divided by  $x_{ij}$ . Then the next term,  $A_{j2} x_{i2}$  divided by  $x_{ij}$  and so on. Then I will have a term  $A_{jj} x_{ij}$ , I divided by  $x_{ij}$ , so that simply gives me  $A_{jj} + \text{etc.} + A_{jn}$  into  $x_{in}$  by  $x_{ij}$ .

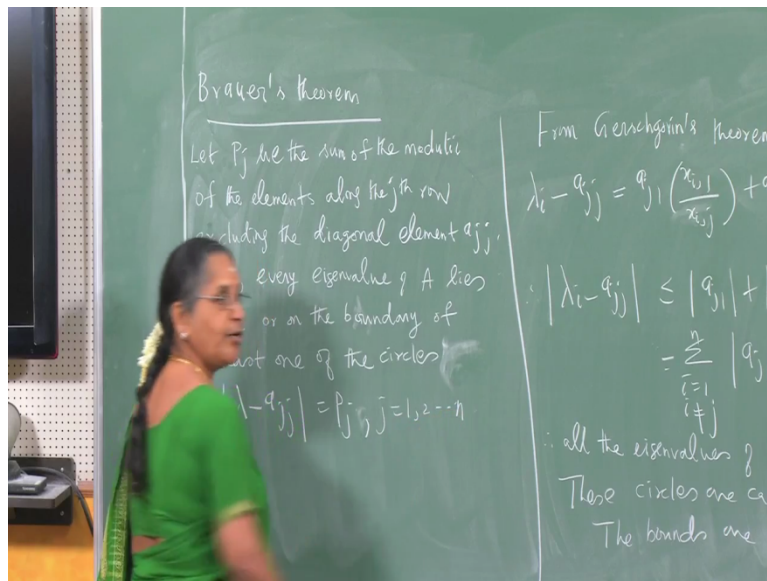

(Refer Slide Time: 41:11)

So if I take the absolute value on both sides, then  $|\lambda_i|$  will be less than or equal to  $|A_{j1}| + |A_{j2}| + \text{etc.} + |A_{jj}| + \text{etc.} + |A_{jn}|$ . Why modulus of  $x_{ik}$  by  $x_{ij}$  is less than or equal to 1, why  $x_{ik}$  in absolute value is the maximum of modulus of  $x_{ij}$ ? And therefore modulus of  $x_{ik}$  by  $x_{ij}$  in absolute value is less than or equal to 1 and therefore  $|\lambda_i|$  is less than or equal to  $|A_{j1}| + |A_{j2}| + \text{etc.} + |A_{jn}|$ . What are these, these are the absolute values of the entries that appear in the  $j$ th equation. And so  $j$  is arbitrary and therefore  $|\lambda|$  is less than or equal to  $\max_i \sum_{k=1}^n |A_{ik}|$ .

And that completes the result that the largest eigenvalue in modulus of a square matrix cannot exceed the largest sum of the moduli of the elements along any row or any column. What about the proof for any column? The matrix  $A$  and  $A^T$  have the same eigenvalues and therefore the proof of the theorem holds good also for columns and hence Gerschgorin's theorem is completed.

(Refer Slide Time: 41:54)

So we now have another result which gives the location of the eigenvalues of the given matrix. It is given by Brauer's theorem and it states that if  $P_j$  is that some of the moduli of the elements along the  $J$ th row, excluding the diagonal elements that are  $A_{JJ}$ , then it says every eigenvalue of  $A$  lies inside or on the boundary of at least one of these circles, which are described as  $\text{mod } \lambda - A_{JJ} \text{ equal to } P_j$  for  $J$  is equal to  $1, 2, 3$  up to  $N$ . So these are circles which have  $A_{JJ}$  as Centre and radius as  $P_j$ . So there are  $N$  such circles and the result says that every eigenvalue of the given matrix  $A$  live inside or on the boundary of at least one of these circles, that is what Brauer's theorem states.

(Refer Slide Time: 43:17)

The proof is very simple, so let us work out the details. We already have seen in Gerschgorin's theorem this step. Namely  $\lambda I$  was written as all these terms  $+ A_{JJ}$  after dividing by  $X_{IJ}$ . So I can bring  $A_{JJ}$  here and write  $\lambda I - A_{JJ}$  is the sum of the rest of the terms. And therefore in absolute value,  $|\lambda I - A_{JJ}|$  will be less than or equal to  $|A_{J1}| + |A_{J2}| + \dots + |A_{J, J-1}| + |A_{J, J+1}| + \dots + |A_{JN}|$ . Why, the reason is modulus of  $X_{IK}$  by  $X_{IJ}$  is less than or equal to 1 for  $K$  running from 1, 2, 3 up to  $N$ . And what is this, this is summation  $I$  is equal to 1 to  $N$ , you see that that is no term  $A_{JJ}$ , so  $I \neq J$  of modulus of  $A_{JI}$  but that is what is denoted by  $P_J$  in the theorem.

So this is equal to  $P_J$ , so what are your circles, your circles are such that they have their centres at  $A_{JJ}$  for  $J$  is equal to 1, 2, 3 up to  $N$  and the radii are given by  $P_J$  for  $J$  is equal to 1, 2, 3 up to  $N$ . So you now know the circles within which the eigenvalues can be located and the result says every eigenvalue of  $A$  lies inside or on the boundary of at least one of these circles which have their Centre at  $A_{JJ}$  and radii at  $P_J$ . So let us now use Gerschgorin's theorem and Brauer's theorem to find out the location of eigenvalues of a given matrix  $A$ .

The Eigen, the circles that we have obtained are called Gerschgorin circles and the bound that we have obtained is called the Gerschgorin's bound. So let us try to determine Gerschgorin's bounds so that we know where all the eigenvalues of a given matrix are located. So we have some important observations to make before we proceed with demonstrating these results. So let us consider these observations. Now we know that  $A$  and  $A$  transpose have the same eigenvalues and therefore all the eigenvalues lie in the union of the  $n$  circles, namely modulus of  $\lambda - A_{jj}$  is less than or equal to  $\sum_{k \neq j} |A_{kj}|$  or  $\sum_{k \neq j} |A_{jk}|$ .

Then secondly all these bounds are independent of each other and therefore all the eigenvalues of  $A$  must lie in the intersection of these bounds. If any of the Gerschgorin circles is isolated, then this circle contains exactly one eigenvalue and if you are given a real symmetric matrix  $A$  such that  $A_{ij} = A_{ji}$ , then in this case we obtain an interval which contains all the eigenvalues. So in case you are given a matrix  $A$  which is the real symmetric matrix, then you can see that, you can obtain an interval which contains all the eigenvalues of this real symmetric matrix.

So let us take an example, suppose say  $A$  is a matrix having entries 3, 2, 2, 2, 5, 2, 2, 2, 3. So let us apply Gerschgorin's theorem and Brauer's theorem and determine the bounds. So all the eigenvalues of this matrix lie in the interval  $|\lambda - A_{jj}| \leq \max\{7, 9, 7\}$ , what is it, it is the row sum or it is also the column sum. So take the 1<sup>st</sup> row, take the entries in the 1<sup>st</sup> row and compute the absolute value of each of the entries and add it or take the entries in the 1<sup>st</sup> column and compute the absolute value of the entries in the 1<sup>st</sup>

column and add that, say add them, then you get value to be 7. Do that for the 2<sup>nd</sup> row and the 3<sup>rd</sup> row or the 2<sup>nd</sup> column and the 3<sup>rd</sup> column.

Which theorem have I applied, I have used Gerschgorin's theorem. So I obtain mod lambda to be less than or equal to 9 and therefore lambda is such that it lies between -9 and 9, this is what my Gerschgorin's theorem says. What does that mean, I have an interval between -9 and 9 in which all the eigenvalues of the given matrix lie. Let us now use Brauer's theorem and see what the result is. The Brauer's theorem tells us the eigenvalues lie in the union of the intervals given by modulus of lambda - A<sub>11</sub> that is 3 less than or equal to P<sub>1</sub>. What is P<sub>1</sub>, the sum of the absolute value of the entries in the 1<sup>st</sup> row, so it is 4.

The 2<sup>nd</sup> condition is modulus of lambda - A 2 2 which is 5 and that is less than or equal to the sum of the absolute value is of the other entries so that is again 4. And from the 3<sup>rd</sup> row we get modulus of lambda -3 is less than or equal to 4. Let us look at the 1<sup>st</sup> inequality, it gives mod lambda -3 less than or equal to 4, mod lambda -5 less than or equal to 4. So -4 less than lambda -5 is less than 4. 1 less than lambda less than 9 and the 3<sup>rd</sup> inequality is mod lambda -3 less than equal to 4 which is the same as the 1<sup>st</sup> inequality. So Brauer's theorem tells us that all the Eigen values lie between -1 and 7 and lambda, all the Eigen values lie between 1 and 9.

Therefore we make use of the results obtained using Gerschgorin's theorem and using Brauer's theorem. The 1<sup>st</sup> inequality says the eigenvalues live between -1 and 7, so it lies in the interval -1 to 7. The 2<sup>nd</sup> inequality says it lies between 1 and 9, so between 1 and 9. And results from Gerschgorin's theorem tells us that lambda lies between -9 and 9, so it lies between say -9 and 9. So now we have to make a conclusion about the interval within which all the eigenvalues lie. So since the bounds are all independent of each other, so we have to find the intersection of these intervals and write down the interval within which all the eigenvalues lie.

So we observe that the intersection of these intervals is -1 less than or equal to lambda less than or equal to 9. So the Eigen values of this given matrix lie in the interval -1 to 9. So if the given matrix A is a real symmetric matrix, then you can find an interval within which all the eigenvalues of the given matrix lie. And I will include more problems on Gerschgorin's bounds in the assignment sheets.
