Indian Institute of Science Education and Research, Pune

Lecture - 01
Part 1
Basic Concepts

Welcome to the first lecture on Graph Theory. My name is Dr. Soumen Maity. I am faculty at Indian Institute of Science Education and Research, Pune. I am grateful to IISER, Pune and NPTEL, IIT Madras for giving me this opportunity to work on this project. This course graph theory is divided into 7 modules. And in the first module we will talk about basic definitions.

(Refer Slide Time: 01:01)

So, these basic definitions will include Eulerian graph, Hamiltonian graph, bipartite graph, complete graph trees and many more. And then next we talk about minimum spanning trees, and here we talk about prims and Kruskal algorithm to find minimum spanning tree in a weighted graph. Third we talk about a matching and we learn how to find maximum matching in bipartite graph. In the fourth module we learn what is vertex cover, and edge cover and also independent set. In the fifth module we learn what is connectivity; we talk about vertex connectivity of a graph and edge connectivity of a graph and how vertex connectivity and edge connectivity are related.

Next we talk about network flows. And in this module we learn how to find maximum flow in a given network using Ford Fulkerson algorithm. Also we learn what is minimum cut and we will prove that the maximum flow is equal to the minimum cut. And finally, we talk about planar graphs and colouring. So, we talk about vertex colouring edge colouring and colouring planar graphs.

So, the reference for this course is introduction to graph theory by DB West and the second reference is graph theory by R Diestel. Let me start with the definition of graph.

(Refer Slide Time: 03:34)

Def. A graph is a pair (V, E) of sets
 Satisfying $E \subseteq V \times V$.
 $V =$ Set of vertices
 $E =$ Set of edges

A graph $G' = (V', E')$ is called a
 Subgraph of graph G if $V' \subseteq V$ &
 $E' \subseteq E$.

A graph is simple if it has
 no loops or parallel edges.

If there is an edge joining v_i & v_j ; then
 they are adjacent. Otherwise they are non-adjacent.

Two or more edges with the same endpoints are called parallel edges.

Ex. e_1 & e_2 are parallel edges
 e_6 is a loop

$G = (V, E)$

So, a graph is a pair V, E of sets satisfying E is a subset of V cross V . Here V is the set of vertices, and E is the set of edges and a graph G prime which is having the vertex set V prime and E prime is called a sub graph or graph G , if V prime is a subset of V and E prime is a subset of E .

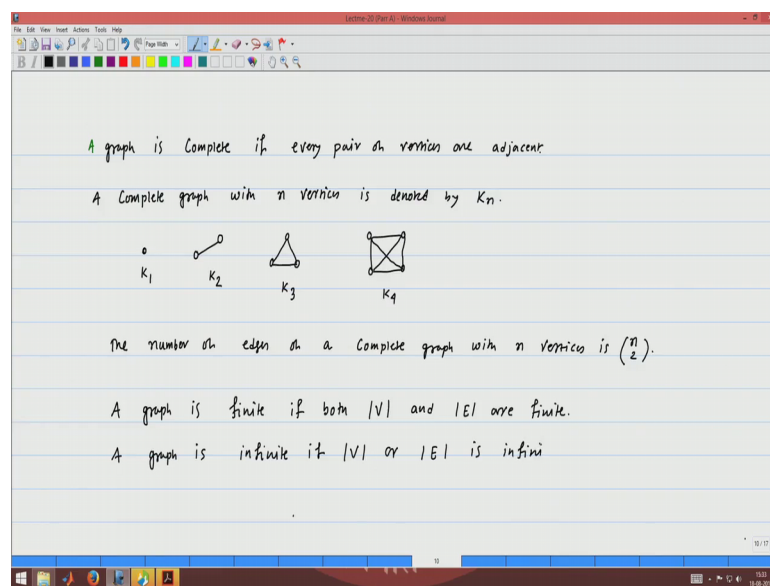

So, let me give an example of a graph. So, these are the vertices of the graph, and I call them v_1, v_2, v_3, v_4, v_5 and an edge joins 2 vertices. So, this edge I call e_1 which joins v_1 and v_2 . This is another edge which joins e_1 and e_2 , I call it e_2 . So, the edge e_7 joins v_1 and v_5 . E_3 joins v_2 v_3 . E_5 joins v_5 and v_3 , and e_4 joins with the v_4 . And e_6 joins v_5 to v_5 ok.

So, this is a graph G with vertex set v_1, v_2, v_3, v_4, v_5 , and the edge set consists of e_1, e_2 up to e_7 . If there is an edge joining v_i and v_j then they are adjacent. So, here you can

see that v_2 and v_3 are adjacent because they are joined by an edge e_3 , whereas, v_2 and v_5 are not adjacent. Otherwise they are non adjacent. 2 or more edges with the same end point are called parallel edges. And a graph simple is simple if it has no loops or parallel edges.

So, for example, here e_1 and e_2 are parallel edges and e_6 . So, e_6 is a loop e_6 is a loop, where as e_1 and e_2 they are parallel edges because they have the same end points.

(Refer Slide Time: 11:04)

So, next we talk about complete graph a graph is complete if every pair of vertices are adjacent.

So, for example, this is a complete graph with one vertex that is called K_1 . So, this is a complete graph with 2 vertices this is denoted by K_2 . This is a complete graph with 3 vertices. This is called K_3 , this is a complete graph with 4 vertices, it is K_4 .

So, a complete graph with n vertices is denoted by K_n . So, definitely the number of edges of a complete graph with n vertices is n choose 2. Because if there are n vertices then every pair of vertices are joined by an edge. So, there will be n choose 2 pairs and n choose 2 edges.

Next a graph is finite if both the number of vertices is a cardinality of V , and cardinality of E are finite. And a graph is infinite if cardinality of V or cardinality of E is infinite. So,

understand special type of graph now that is called complete graph, and K_n is denoted is the notation for complete graph with the n vertices.

Now, next we learn what is degree of a vertex. So, definition the degree of a vertex V in a graph G denoted by $d(V)$ is the number of edges of G incident to V .

(Refer Slide Time: 15:47)

Def: The degree of a vertex v in a graph G , denoted by $d(v)$, is the number of edges of G incident to v .

A graph G is said to be k -regular, if $d(v) = k$ for all vertices $v \in V$.

A Complete graph on n vertices is $(n-1)$ -regular.

C_4 : 2-regular graph

Diagram 1: A graph with vertices v_1, v_2, v_3, v_4 . v_1 has a loop and is connected to v_2 and v_3 . v_2 is connected to v_1, v_3 , and v_4 . v_3 is connected to v_1, v_2 , and v_4 . v_4 is connected to v_2 and v_3 .
 $d(v_3) = 2, d(v_4) = 2$
 $d(v_2) = 3, d(v_1) = 3$

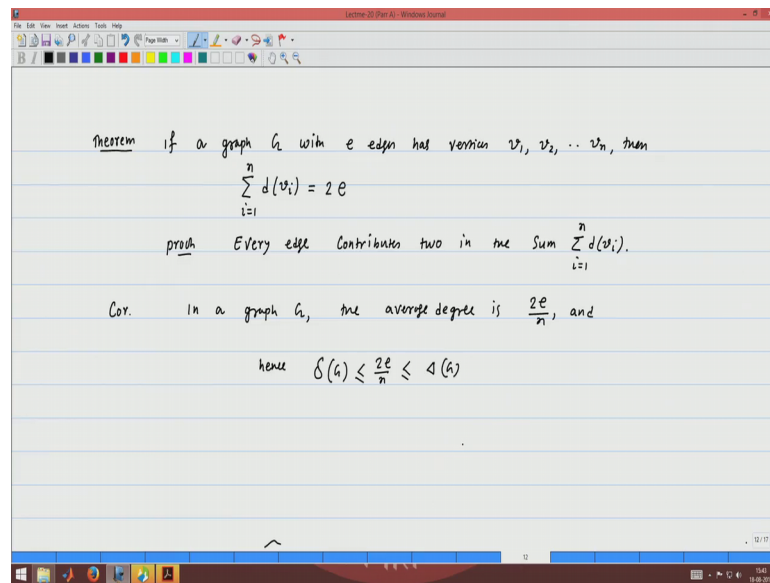

Diagram 2: A square cycle graph C_4 with 4 vertices and 4 edges, labeled as a 2-regular graph.

So, let me give an example of a graph. So, I will label these vertices by v_1, v_2, v_3, v_4 and there is a loop here. So, here you can see that the degree of v_3 is equal to 2 because 2 edges are incident to v_3 degree of v_4 is also 2 because there are 2 edges incident to v_4 . Degree of v_2 is equal to 3, because there are 3 edges incident to v_2 and the degree of v_1 is also 3 because this will be counted 2 degree plus 1 degree here.

A graph G is said to be k regular if the degree of V is equal to k for all vertices V belongs to G . So, an example of a regular graph this is called C_4 cycle of length 4 you will learn soon. So, here you can see that the degree of every vertex is 2. So, this is 2 regular graph. And one observation that a complete graph, graph on n vertices is $(n-1)$ regular.

So, this is because a complete graph with n vertices. Every vertex is adjacent to all the remaining $n-1$ vertices. So, every vertex is having degree $n-1$. So, a complete graph with n vertices is $(n-1)$ regular. Next we talk about a theorem.

(Refer Slide Time: 20:42)

If a graph G with E edges has vertices v_1, v_2, \dots, v_n . Then the degree sum degree of the vertex v_i , i equal 1 to n is equal to twice the number of edges.

So, E stands for the number of edges and n stands for the number of vertices. So, in our previous example if I see that here the degree sum there are 4 vertices. So, the degree sum is summation of d_i , sorry d of v_i i equal from 1 to 4 is equal to 10. And this graph has 5 edges. So, E equal to 5. So, this degree sum is equal to twice of E right. So, it is easy observation because the proof is that every edge contributes 2 in the degree sum right. That is why this is the degree sum is equal to n .

So, we can see here that this edge for example, this is contributing 2 degree in the degree sum. So, one degree is counted as degree of v_4 degree of v_4 is 2 because of this edge and this edge. And the degree of v_3 is also 2 because of this edge and this edge. So, this edge is contributing 2 in the degree sum that is why the degree sum is twice the number of edges. Now we denote something called maximum degree; so that this notation that Δ of G is equal to the maximum degree. So, we will use this notation several times and the maximum degree here is 3. So, this is 3 here and small δ G is the notation for minimum degree, and the minimum degree here is 2, right.

Now, corollary of this theorem in a graph G , the average degree is twice e by n , because this is the degree sum and there are n vertices. So, that is average degree of every vertex is twice e by n . And obviously, this average degree twice e by n . It will be smaller than

the maximum degree and this will be the average degree will be greater than the minimum degree of the graph G . So, these are all fine.

Next we talk about another theorem.

(Refer Slide Time: 26:09)

Theorem In any graph G , the number of vertices with odd degree is even.

proof Let v_1, v_2, \dots, v_n be vertices of G

Suppose v_1, v_2, \dots, v_t are odd vertices
 $v_{t+1}, v_{t+2}, \dots, v_n$ are even vertices

$d(v_1) + d(v_2) + \dots + d(v_t) + d(v_{t+1}) + \dots + d(v_n) = 2E$

$d(v_1) + \dots + d(v_t) = 2E - \underbrace{(d(v_{t+1}) + \dots + d(v_n))}_{\text{even}}$

$d(v_1), d(v_2), \dots, d(v_t)$ are all odd, so t must be even.

This says that in any graph G the number of vertices with odd degree is even. So, if I draw this graph again, now these vertex has degree 2 this vertex has degree 2 this vertex has degree 3 this vertex has degree 3. Now you can see that the number of vertices having odd degree is 2. And that is always true, why this is true? Here is the proof of this. Let v_1, v_2, \dots, v_n be vertices of G . And for simplicity suppose v_1, v_2, \dots, v_t they are odd vertices. And $v_{t+1}, v_{t+2}, \dots, v_n$ are even vertices. The meaning of this one is that odd vertices means the vertices with odd degree even vertices means the vertices with even degrees. So, these are the even vertices these are the odd vertices.

Now, what we know is that we know that the degree of v_1 plus the degree of v_2 plus the degree of v_t plus the degree of v_{t+1} plus the degree of v_n that is the degree sum is equal to twice E right. Now what we can do is that I can write degree of v_1 plus degree of v_t these are the odd vertices equal to twice E minus degree of v_{t+1} plus degree of v_n . Now this is $2E$ is even and these are all even vertices.

So, this is also even. So, this is even. So, the whole thing the right hand side is even right. The whole thing is even, even minus even. So, it is even now we know that this

each term here they are odd because this is the odd degree. So, the left hand side this will be even only if the number of terms are the number of terms is even. So, here degree of v_1 degree of v_2 degree of v_t are all odd, but their sum is even the sum is even. So, t must be even and the t is the number of odd vertices. So, what you have proved is that if in any graph the number of vertices with odd degrees is even.

So, in the first part of first lecture we have learnt some basic definitions like degree of vertex and some related results. In the second part we learn what is walk trail connected graph complement of a graph, and many more.

Thank you very much.
