Lecture – 18
Part 2
Chromatic Number and Max. Degree

Welcome to the second part of lecture 18 on Graph Theory. In the first part of this lecture we talked about 2 lower bounds for chromatic number of a graph. That chromatic number of a graph is always greater than equal to the tick size of the graph, and the other one is that the chromatic number of the graph is greater than or equal to the cardinality of b by maximum independent set size.

(Refer Slide Time: 01:00)

Lecture -18 (Part B)

Proposition 2 $\chi(G) \geq \frac{|V(G)|}{\alpha(G)}$

Remark This bound could be very loose.

Ex.

$(K_1) \quad (K_1) \quad (K_1) \quad \dots \quad (K_1) \quad (K_k)$
 G
 n components

$\alpha(G) = n, \quad |V(G)| = n-1 + k$

$k = \chi(G) \geq \frac{|V(G)|}{\alpha(G)} = \frac{n-1+k}{n} < 2$ for large n .

So, the second bound that we got is the proposition 2 probably that $\chi(G)$ is greater than equal to $|V(G)| / \alpha(G)$. Now one remark sometime this bound works fine, but they could be very loose also sometime. So, this bound could be very loose, and we give an example to sort of support this remark. Let me concentrate this graph. This graph has n components, n components. The first component is K_1 ; that means, just one vertex.

The second component is also complete graph with one vertex; that means, just a single vertex. And you have such components $n-1$ such components right. And then the n th component is complete graph with k vertices. So, this is the graph G it has n

components is the graph G . Now what is the size of maximum independent set for what is $\alpha(G)$ here? $\alpha(G)$ is clearly n because you can pick in the independent set $n - 1$ vertices from $n - 1$ components, and one vertex from k . So, that will give you independent size maximum independent set of size n . And what is the number of vertices here $V(G)$ is equal to here you have k vertices, and in this $n - 1$ components you have $n - 1$ vertices, so $n - 1 + k$.

Now, what is the chromatic number of this graph G the chromatic number of this graph is like we have used that you can use that result that chromatic number of a graph G is maximum of chromatic number of different components. So, c is a component. So, this component required one color this component required, one color this component required one color, but this component required k colors. So, the chromatic number of this graph is maximum of $1, 1, 1$ and k which is equal to k right.

So, as we can see that the chromatic number is k , and our this bound gives that $\chi(G)$ is greater than equal to $V(G) / \alpha(G)$, which is $(n - 1 + k) / n$. And this will be less than 2 for large n right. That is easy to see, but actual chromatic number is k . So, the lower bound says that the chromatic number is something less than 2 , but actual chromatic number is k . So, that is mean for this graph the bound given by this proposition 2 is very loose ok.

So, we talked about 2 lower bounds for chromatic number. Now we move to upper bound for chromatic number.

(Refer Slide Time: 06:54)

Chromatic number & Max degree

The colours are $1, 2, 3, \dots$

The greedy colouring relative to a vertex ordering v_1, v_2, \dots, v_n on $V(G)$ is obtained by colouring the vertices in the order v_1, v_2, \dots, v_n . Assign to v_i the smallest indexed colour not already used for its neighbours among v_1, v_2, \dots, v_{i-1} . In a vertex ordering, each vertex has at most $\Delta(G)$ earlier neighbours.

So, the greedy algorithm cannot force to use more than $\Delta(G) + 1$ colors.

Ex.

x_1	x_2	x_3	x_4	x_5	x_6	x_7	x_8
1	1	1	1	2	2	2	2

x_1	x_2	x_3	x_4	x_5	x_6	x_7	x_8
1	1	2	2	3	3	4	4

And we give a greedy algorithm to color the vertices of a graph. So, chromatic number and its relation with maximum degree. And also this talk about the upper bound for chromatic number. So, I will start with an algorithmic technique to color the vertices of a graph, the colors are 1 2 3 like this. You are not really going to use different colors we will use numbers instead of colours ok.

Now, what is this greedy colouring algorithm? The greedy colouring relative to a vertex ordering v_1, v_2, \dots, v_n . So, this colouring algorithm depends on how you order the vertices of the graph G . And the greedy colouring relative to a vertex ordering is obtained by colouring the vertices in the order v_1, v_2, \dots, v_n . So, you choose an arbitrary ordering of the vertices. This algorithm does not say how you ordered the vertices.

So, you have to just decide on an arbitrary ordering of the vertices. And then you colour the vertices in this order you colour the vertex v_1 first. And then v_2 first with this specific rule you assign to v_i in the i th step assign to v_i the smallest indexed colour not already used for its neighbour among v_1, v_2, \dots, v_{i-1} . I will explain this one among v_1, v_2, \dots, v_{i-1} . And in a vertex ordering, what about ordering you take it does not matter each vertex has at most $\Delta(G)$ neighbour on the left or earlier neighbours.

So, the greedy algorithm cannot force to use more than $\Delta(G) + 1$ colors. So, this is what the algorithm is, but I need to explain it. So, what you do is that a given a graph you just decide on an arbitrary ordering of the vertices, and then you colour the vertices in

this order only. So that means, you colour v_1 first and then v_2 first. So, when you are assigning a color to v_2 for example, you use the smallest index colour not already used for it is neighbour on the left hand side; that means, you use the smallest index colour for v_2 which is not used for v_1 provided v_1 is neighbour of v_2 . And the number of colours required to greedily colour the graph it depends on what ordering you have taken.

If you change the ordering of the vertices the number of colours required to colour the graph might differ. So, I will give an example that how the number of colours required by the greedy algorithm changes when you change the order of the graph order of the vertices. So, let me give this example. So, I considered a bipartite graph, say this one. You have 4 vertices in the left side and 4 vertices on the right side and I call them or level them x_1, x_2, x_3, x_4 on the left and x_5, x_6, x_7, x_8 on the right.

So, x_1 is adjacent to x_7, x_6, x_5, x_2 is adjacent to x_8, x_6 and x_5 . x_3 is adjacent to x_5, x_7 and x_8 and x_4 is adjacent to x_6, x_7 and x_8 . Now the algorithm does not know that whether this is a bipartite graph or some other graph. So, it will decide on some arbitrary ordering if I choose this ordering for example, is $x_1, x_2, x_3, x_4, x_5, x_6, x_7$ and x_8 .

Suppose this is the ordering I decide one and then I will start colouring with x_1 and I will colour this vertex x_1 1. So, I give colour 1 to x_1 . Now when I colour x_2 I will use the smallest index colour not already used for it is neighbour among the previous on it is it is neighbour on the left hand side. So, x_2 's neighbour on the left hand side is no neighbour on the left hand side. So, I can use the smallest index colour that is available. So, I can use one again for x_3 , it does not have. So, x_1 and x_2 are not neighbour of x_3 . So, I cannot you I can use the same colour one x_4, x_1, x_2, x_3 are not neighbour of x_4 .

So, I look at the neighbour of a vertex x_i on it is left hand side only. I do not look at the right hand side at this moment. So, I can give colour one. Now for x_5 I look at it is neighbour on the left hand side. So, x_5 has neighbour x_3, x_2, x_1, x_3, x_2 and x_1 . So but all of them are coloured one, so the colour among the colours 1 2 3 4. I can use the smallest index colour for x_5 that is 2 right. For x_6 again I look at it is neighbour on the left hand side and the neighbour of x_4 are sorry, neighbour of x_6 are x_4, x_2 and x_1 all of them are coloured one. So, I can use colour 2 for x_6 .

Similarly, for x_7 you can check that all its neighbours on the left hand side are coloured one. So, I can use colour 2 for x_7 and similarly for x_8 I can use colour 2 again. Now it is good that you got a greedy algorithm coloured this bipartite graph with 2 colours, as I said that if you change the ordering of the vertices the required number of colours might change. So, if you take this ordering for example, say x_1, x_1 because you can start with any arbitrary ordering, and the number of colours required depends on what ordering you choose.

So, $x_1, x_8, x_2, x_7, x_3, x_6, x_4, x_5$. Now if you choose this ordering, because the ordering is an arbitrary ordering you do not know in which order you have to color the vertices. So, if you choose this ordering then first for x_1 you can use colour one fine for x_8 it has no neighbour on the left hand side. So, again you can use the colour one. Now for x_2 has neighbour on the left hand side 8. So, you cannot use colour one again for x_2 because x_2 which is adjacent to x_8 . So, you have to use the smallest index colour which has been not used for it is neighbour on the left hand side. So, you have to use colour 2 for x_2 .

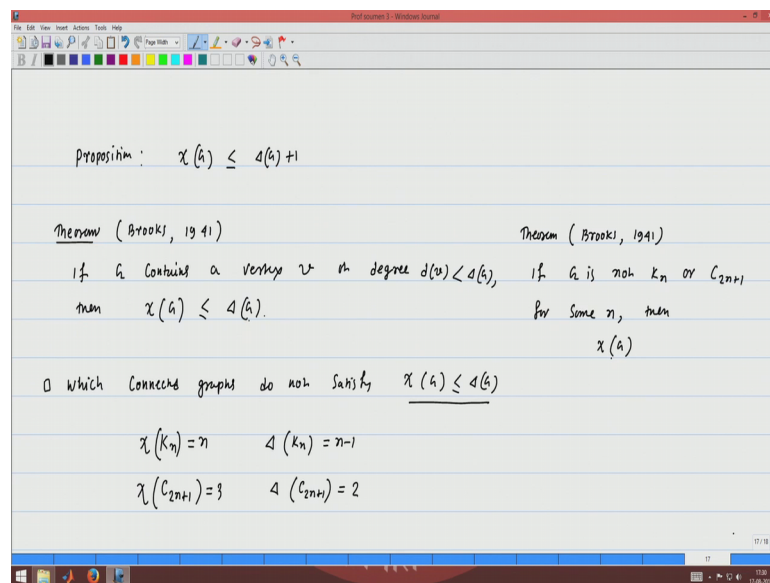

Now, look at x_7 , x_7 has neighbour x_1 and x_1 is coloured with one. So, for x_7 you have to use the smallest index colour available that is 2. Now go to x_3 , x_3 has 3 neighbours x_5, x_7 and x_8 . So, the neighbours of x_3 is x_7 and x_8 on the left hand side. So now, you can see that the 2 neighbours of x_3 they are already coloured 1 and 2. So, x_3 cant. So, x_3 has to use the next smallest index colour available. So, x_3 will be coloured with colour 3. And similarly x_6 is on the left hand side it has neighbour x_2 and x_1, x_2 and x_1 .

I can remove this 2 now and they are coloured 1 and 2. So, the smallest index colour not used for it is neighbour on the left hand side that is 1 2 are already used. So, you have to use colour 3 for x_6 . Now look at x_4 . x_4 has neighbour x_6, x_7 and x_8 . x_8 is one neighbour for x_4 on the left hand side. x_7 is another neighbour for x_4 and x_6 is also a neighbour of x_4 . And so, the neighbours have already used the colour 1 2 and 3. So, you have to use the next smallest available colour that is 4, smallest indexed colour that is 4. And similarly for x_5 you can check that you have to use colour 4.

So, for this ordering you can see that the number of colours used by the greedy algorithm is 4. So, this explains that how many colours you need to use by the greedy algorithm

that depends on completely on the ordering of the vertices how do you order the vertices. And this algorithm does not talk about how to order the vertices. So, that the number of colours required will be less. So, this example explains that if you change the ordering of the vertices you required different number of colours right. So, we talk and clearly when you are colouring the i th vertex v_i , it can have maximum $\Delta(G)$ neighbours on the left hand side.

(Refer Slide Time: 24:12)

On it is left because the degree of this vertex is maximum $\Delta(G)$ right. And it might happen that all the neighbours on it is all the $\Delta(G)$ neighbours they have different colours.

So, for v_i you have to assign $\Delta(G) + 1$ the colour $\Delta(G) + 1$. So, that is why this proposition is a obvious consequence of the greedy algorithm, that this gives upper bound that $\Delta(G)$ is always less than or equal to $\Delta(G)$, sorry chromatic number of G is always less than equal to $\Delta(G)$ $\Delta(G)$ is the maximum degree of the graph G plus 1. So, this is also explained in the in the greedy algorithm, that in any vertex ordering each vertex v_i has at most $\Delta(G)$ neighbours on it is left. So, the greedy algorithm cannot force to use more than $\Delta(G) + 1$ colours.

So, this clearly says that the chromatic number of the graph G is always less than equal to the maximum degree plus 1. So now, just for information we talk about some theorems results known in this area theorem, Brooks theorem 1941. It says that if G

contains a vertex v of degree d_v strictly less than ΔG ; that means, it is not a ΔG regular graph. That is at least one vertex which has degree less than the highest degree.

Then you can improve this upper bound slightly that ΔG sorry the chromatic number of the graph G is less than equal to ΔG . So, in this case when there is a vertex of degree strictly less than ΔG , you can this theorem gives an ordering of the vertices which requires depth first search, which is a technique in algorithm you start with one vertex and systematically you visit all the vertices which are accessible from the vertex v . So, since we do not know depth first search algorithm we will not talk about the proof of this algorithm.

But the outline of this outline of the proof of this theorem that you start with vertex v which has degree strictly less than ΔG and applied d f s. And so, the d f s will give you ordering of the vertices. And you colour the vertices of the graph in a reverse order of the d f s. So, this is just for information that you can improve your result slightly instead of $\Delta G + 1$ it can be ΔG only. Now one which connected graphs do not satisfy this condition. This is just a remark of observation that χ of G is less than equal to ΔG .

You look at this complete graph with n vertices. We know that χ of K_n is equal to one sorry, is equal to n . And Δ of K_n is equal to $n - 1$. So, here this connected graph K_n the complete graph with n vertices does not satisfy this condition. Another graph is cycle with odd number of vertices C_{2n+1} . And we know that what cycle has chromatic number 3 and the maximum degree of cycle C_{2n+1} is equal to 2.

So, χ of C_{2n+1} is $\Delta + 1$ basically right. So, here is the other theorem again by Brooks 1941, that if G is not K_n it is not a complete graph or not a odd cycle C_{2n+1} for some n , except this 2 graphs for the other graphs χ of G . Of course, I am talking about connected simple graphs χ of G is less than equal to ΔG . So, that is all. So, we have learnt what is a chromatic number of a graph. And we talked about it is lower bound using the clique number maximum clique size and maximum independent size, size of maximum independent set. And also we talked about upper bound based on the maximum degree of the graph G . That is all for today.

Thank you very much.
