## *Application of Fourier Transform to ODE's*

Dr. Srinivasa Rao Manam  
Department of Mathematics  
IIT Madras

Welcome back, the last video we have seen the rigorous proof of Fourier integral theorem, so like that given a function  $F(x)$  if you start with and do the Fourier series, write its Fourier series and you fix some  $X$  values you will see that you end up getting some number series, and that number series, the value of the number series, some of the series is known.

The same way in the Fourier integral formula you can substitute some non-periodic signal that is a piecewise continuous and absolutely integrable function  $F(x)$ , left hand side is  $F(x)$  and the right hand side you have a double integral and if you can evaluate to one part of the integral and what remains is the other integral, so we will see that some integration, some integrals values you know analytically you know from this formula, okay, that we will do later that is one application of this Fourier integral formula.

So once you have this Fourier integral formula, so now we can define what is a Fourier transformer and its inverse transform, so that is legitimized, whatever we have defined its Fourier transform and its inverse transform and you have certain properties that we have proved based on these properties you make use of all these properties and we try to solve some problems, the first thing is what do you mean by problem, problem is, you try to apply this Fourier transform to solve certain problems in physics and engineering, so for example problems means either there are ordinary differential equations with initial conditions or ordinary differential equation over a domain with boundary conditions, so something like that if you have some ordinary differential equation, linear ordinary differential equations you can easily solve by applying Fourier transform.

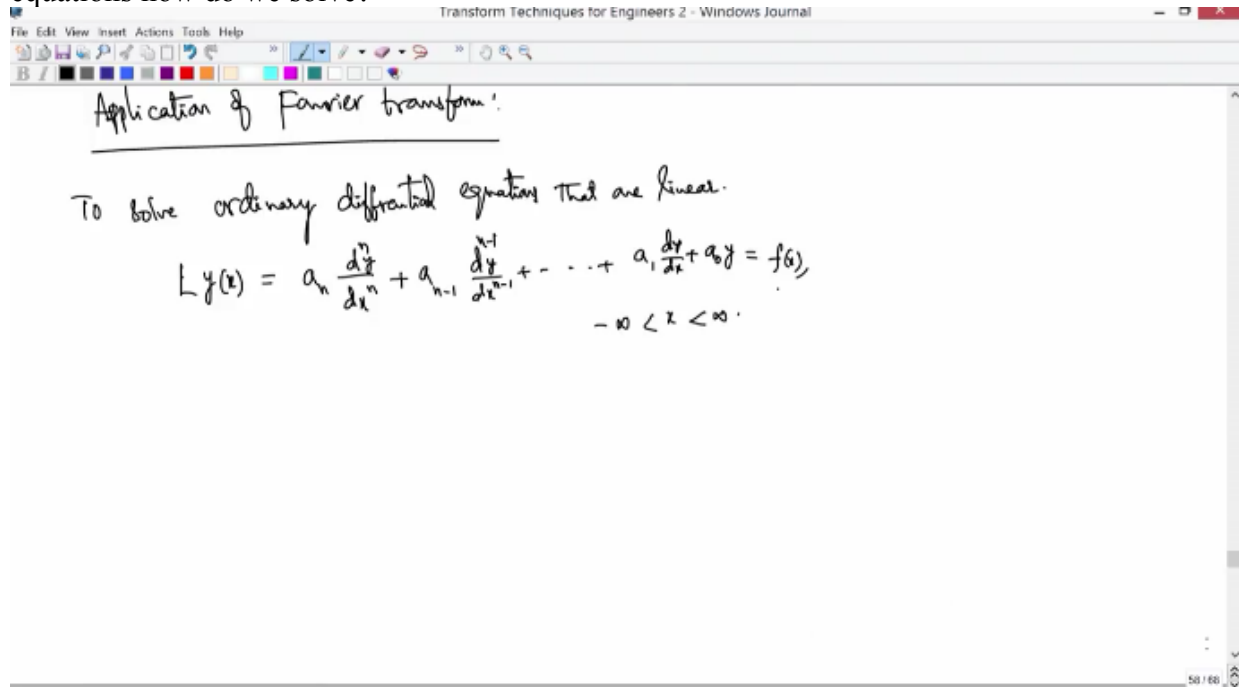

And the same way if you have some PDE's, partial differential equations, so partial differential equations if you have seen in differential equations course any linear partial differential equations in two variables so that is that you can classify into three type of typical equations, so a typical of such equations for elliptic type we have a Laplace equation, and for parabolic type it's a heat equation, and for hyperbolic equation, hyperbolic type equations you have a wave equation, so you have typically three equations which are a wave equation, heat equation, and Laplace equation that is you can also think of 2-dimensional version of parabolic heat equation that is a steady state of a heated plate, okay, so if you think of like that so it's you will get a 2-dimensional Laplace equation, and so these are the 3 typical equations which you can think of as a from, any second, in two variable, second-order partial differential equation in 2 variables. Then you can solve such problems over certain domains that's what we have seen in the differential equations course if you have seen early, if you have done differential equations for engineers you have seen how to solve partial difference, such partial differential equations in certain domains.

So those similar such problems, these linear equations, these are actually linear equation all three types, these equations with some boundary conditions are initial conditions, you can actually solve by using the transform techniques either Fourier transform the later on you can apply a Laplace transform at other transforms which you can use, okay, so you have to suitably, you have to use these transforms and try to solve this boundary value problem, so that is one such application so you can solve ordinary differential equations with initial conditions, partial differential equations with initial and boundary conditions and this is one application and you can also, based on the properties of the Fourier transform you can evaluate some integrals of other type of equations that you can solve other application of partial Fourier transform is solving integral equations, so integral equation is you have something like same like it's analogous to the differential equation, in the differential equation what we mean is an unknown in the derivative, so in the same way if you think of, if your unknown is in the integral under some, under integral that is called the integral equation, so if you can solve certain type of integral equation I will give you the certain form of such linear integral equations you can solve by a Fourier transform, so that is another application of this Fourier transform so we will see one by one.

So let's see the applications, application of Fourier transform, Fourier transform now we mean many, so what we mean is Fourier transform so either Fourier coefficient that is a Fourier transform as in a complex form over a finite interval or you can think of if it is an even function or odd function depending on that you have either sine transform or cosine transform you call this CN, N even you call this cosine transform or rather if you are working with CN, CN's are a complex Fourier transform of a finite signal, and if you have Fourier series in terms of AN, and BN, if AN's are 0 and BN's are nothing but Fourier sine transform, and AN's are Fourier cosine transform is just for the namesake, so those are over for transforms over a finite intervals, okay, so later on what we have is a Fourier transform over a full real line that is in terms of exponential function integral minus infinity infinity  $F(x)$  into exponential function.

And also we have defined in a different place so if your function is defined only on from 0 to infinity and semi-infinite intervals if you have, you have a cosine transform and sine transform and it's inverse transform, so depending on what is your domain, we will try to apply there one of these transforms ordinary differential equation, first application is to solve ordinary differential equations, equations that are linear, linear of any order so let us choose LY, so let me call this LY is an unknown, this is depending on only one variable, one independent variable X so that is what is called ordinary differential equation, this is you have some constant AN so and you have the nth derivative of Y and you have AN-1, N-1 derivative of Y and so on you end up getting A1

$DY/DX + A$  naught,  $A$  naught of  $Y$  equal to, if you have some forcing, so in the systems normally you get the right-hand side  $F(x)$  this is called a forcing term, that means an application basically if you have some force outside force this is the governing equation will have on the right hand side that is a non-homogeneous term, so you have this such equation is if you get an equation like this, this is a linear ordinary differential equation of order  $N$ , okay, so such equations how do we solve?

So first of all to see this equation immediately, what is your domain? Domain is from minus infinity to infinity, so that is what it means if nothing is given means our domain is minus infinity to infinity, so how do I solve this by using Fourier transform? So you will have a Fourier transform over full real line so if you apply  $Y$  cap you apply Fourier transform, for example if your domain is 0 then I apply Fourier cosine transform or sine transform, okay, and once you have this domain the boundary is this,  $X = 0$  is the boundary on that you should have the information that is  $N$  initial conditions and boundary conditions you should have, okay, so at  $X = 0$  this is an initial value problem so once you have this 0 to infinity because there is a boundary in your domain, so at which you have to give the boundary initial conditions, at 0 you should provide the initial conditions, so  $Y$  at 0 and  $Y$  dash at 0 up to  $Y^{(N-1)}$  at 0 you have to provide conditions, so once you give these conditions you apply this cosine transform or sine transform, so right now we have this minus infinity to infinity, so these things we will see as and when you do the problems, that depending on the domain how we apply the Fourier sine transform or cosine transform, we will see that when we do the applications and we do the problems.

So right now I have to consider this general problem, general just equation so how do we solve this apply, we apply Fourier transform, so what you get is  $AN$   $DY/DX$  power  $n$  for which whole function of  $x$  and you have similarly  $AN-1$   $DY$ , these are constants, okay, where  $AN$ ,  $AN-1$  up to  $A1$ ,  $A0$  are constants, let us take it as constants, okay if it is function of  $X$  still have to worry so because it's a product of two functions, so you have to consider such a transform, so if it is constants as of now it is easy, so you will consider like this  $DN-1$  derivative, for this if you take the Fourier transform and so on, so you end up getting  $A1$   $DY/DX$  for which you take the

Fourier transform and you have A naught Y transform, Y is a function of X, A naught is constant, so what you get is Fcap(xi), xi belongs to full realline, so this is what you have if you apply.

To solve ordinary differential equations that are linear.

$$L\{y(x)\} = a_n \frac{d^n y}{dx^n} + a_{n-1} \frac{d^{n-1} y}{dx^{n-1}} + \dots + a_1 \frac{dy}{dx} + a_0 y = f(x),$$

$-\infty < x < \infty$   
 $a_n, a_{n-1}, \dots, a_1, a_0$  are constants.

Apply Fourier transform,

$$a_n \frac{d^n Y}{d\xi^n} + a_{n-1} \frac{d^{n-1} Y}{d\xi^{n-1}} + \dots + a_1 \frac{dY}{d\xi} + a_0 Y = F(\xi),$$

Now because AN is a, it's linear, transformation is linear so AN is because it's a constant it comes out and this nth derivative is I xi power N into, if you repeatedly do the integration by parts and in the definition of the Fourier transform you bring, you send all these nth derivatives on to exponential function and what you get is Fourier transform of Y, and this is what is the Fourier transform of nth derivatives. So like this you go on so you have AN-1, constant comes out, I xi power N-1 into Y cap(xi), so you see that every time you are ending up only Y cap, Fourier transform of Y so when you get A1 I xi into Y1 cap, Y cap (xi) + A naught Y cap(xi) which is equal to F cap(xi) this is what you get, so what we need is, so Y cap is, Y cap(xi) is common, Y cap(xi), and what is this one? This is actually equal to if you because the way you have defined LY is this, so what you end up is so L of, so this is a polynomial right so you cannot write in terms of L though L is some operator, so let me write it as a polynomial, so AN I xi power N up to A1 into I xi + A naught, this is the polynomial in xi, which is equal to F cap

Transform Techniques for Engineers 2 - Windows Journal

10 solve

$$L y(x) \equiv a_n \frac{d^n y}{dx^n} + a_{n-1} \frac{d^{n-1} y}{dx^{n-1}} + \dots + a_1 \frac{dy}{dx} + a_0 y = f(x),$$

$-\infty < x < \infty$   
 $a_n, a_{n-1}, \dots, a_1, a_0$  are constants.

Apply Fourier transform,

$$a_n \widehat{\frac{dy}{dx}}(\xi) + a_{n-1} \widehat{\frac{d^{n-1} y}{dx^{n-1}}}(\xi) + \dots + a_1 \widehat{\frac{dy}{dx}}(\xi) + a_0 \widehat{y}(\xi) = \widehat{f}(\xi),$$

$\xi \in \mathbb{R}$ .

$$a_n (i\xi)^n \widehat{y}(\xi) + a_{n-1} (i\xi)^{n-1} \widehat{y}(\xi) + \dots + a_1 (i\xi) \widehat{y}(\xi) + a_0 \widehat{y}(\xi) = \widehat{f}(\xi).$$

$$\widehat{y}(\xi) (a_n (i\xi)^n + \dots + a_1 i\xi + a_0) = \widehat{f}(\xi).$$

(xi), so if you call this some Q(xi) or whatever, so let's call this some PN(xi) nth degree so you have Ycap(xi) is actually F cap(xi) divided by PN(xi), so what we need? We have now this one xi belong to R, now if you can take the inverse transform here so what you get, if you take the inverse transform for Y you get your YX, that is exactly the solution of this equation, so such a solution is actually inverse transform of this that is actually minus infinity to infinity, 1/root 2 pi F cap(xi)/PN(xi), E power I xi X D xi, so this is exactly your solution if you can evaluate this nicely that is what you will get as a solution, so this is the general procedure to find the solution of this equation, okay.

Transform Techniques for Engineers 2 - Windows Journal

$$a_n \widehat{\frac{dy}{dx}}(\xi) + a_{n-1} \widehat{\frac{d^{n-1} y}{dx^{n-1}}}(\xi) + \dots + a_1 \widehat{\frac{dy}{dx}}(\xi) + a_0 \widehat{y}(\xi) = \widehat{f}(\xi),$$

$\xi \in \mathbb{R}$ .

$$a_n (i\xi)^n \widehat{y}(\xi) + a_{n-1} (i\xi)^{n-1} \widehat{y}(\xi) + \dots + a_1 (i\xi) \widehat{y}(\xi) + a_0 \widehat{y}(\xi) = \widehat{f}(\xi).$$

$$\widehat{y}(\xi) (a_n (i\xi)^n + \dots + a_1 i\xi + a_0) = \widehat{f}(\xi).$$

" P<sub>n</sub>(ξ)

$$\Rightarrow \widehat{y}(\xi) = \frac{\widehat{f}(\xi)}{P_n(\xi)}, \quad \xi \in \mathbb{R}$$

$$\Rightarrow y(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} \frac{\widehat{f}(\xi) \cdot e^{i\xi x}}{P_n(\xi)} d\xi.$$

So this one so if you actually if you know the differential equation theory because if it is the  $n$ th order differential equation the solution you might have seen  $C_1$  times  $Y_1$ , and  $C_2$  times  $Y_2$ , and  $C_N$  times  $Y_N$ , which is homogeneous solution, plus some particular solution  $Y_p(x)$ , what you get here by this solution is called particular solution, when you put  $Y$  equal to,  $F$  is 0 you're getting  $Y = 0$ , okay, so if you take  $F = 0$  so your solution what you got by Fourier transform you put  $F$  cap, if  $F$  is 0,  $F$  cap is 0 so that makes it  $Y = 0$ .

Transform Techniques for Engineers 2 - Windows Journal

Application of Fourier transform:

To solve ordinary differential equations that are linear.

$$L y(x) \equiv a_n \frac{d^n y}{dx^n} + a_{n-1} \frac{d^{n-1} y}{dx^{n-1}} + \dots + a_1 \frac{dy}{dx} + a_0 y = f(x),$$

$-\infty < x < \infty$   
 $a_n, a_{n-1}, \dots, a_1, a_0$  are constants.

Apply Fourier transform,

$$\widehat{a_n \frac{dy}{dx^n}}(\xi) + \widehat{a_{n-1} \frac{dy}{dx^{n-1}}}(\xi) + \dots + \widehat{a_1 \frac{dy}{dx}}(\xi) + \widehat{a_0 y}(\xi) = \widehat{f}(\xi),$$

$\xi \in \mathbb{R}$ .

$$a_n (i\xi)^n \widehat{y}(\xi) + a_{n-1} (i\xi)^{n-1} \widehat{y}(\xi) + \dots + a_1 (i\xi) \widehat{y}(\xi) + a_0 \widehat{y}(\xi) = \widehat{f}(\xi).$$

$$\widehat{y}(\xi) (a_n (i\xi)^n + \dots + a_1 i\xi + a_0) = \widehat{f}(\xi).$$

If  $F = 0$  you get  $Y(x) = 0$ , so from this method, okay, from this is what you get, so that means you're not actually calculating homogeneous solution but this particular solution okay, that is actually the general solution of this equation okay, so that's how we solve, we get only a particular solution here, so by just if you do like this you get a particular solution because there is no boundary involved here, okay, so if you are given a full solution full domain if you apply the Fourier transform what you get is only particular solution, okay.

So let's do some examples, we start with an example here where we use full Fourier transform it's an example what we considered here is  $D^2 Y + 3DY + 2Y = E^{-X}$ , so what is surprising here is if I take  $X$  full real numbers  $E^{-X}$ , when  $X$  is negative this is unbounded thing so that you cannot take the Fourier transform so that is not absolutely integrable function, from  $-0$  to minus infinity or minus infinity to 0, so what is given the domain is actually positives in this you have to solve, and the boundary initial conditions are, so this is  $Y(x)$ , the domain is this 0 to infinity this is the domain and on which you have initially because it's a second-order equation you have got given two initial conditions so those are  $Y'(0)$  and  $Y(0)$  they are given as 0, okay, so and what is the other boundary? This is infinity you can assume that  $Y$  and  $Y'$  they are going to 0 as  $X$  goes to infinity, so this is because you have the infinity, okay.

Once you have such a thing so this is your problem, so if you view this as an initial value problem and you can consider this as an initial value problem if you choose only this one, and if you choose one of the values, one of these conditions here and then if you use this one that is a boundary value problem, so let's solve only initial value problem as of now, so let's take this initial value problem let's solve and then solution goes like this, so how do we solve this? What is given is on

X positive side you have this  $Y(x)$  is defined, and so how are we going to solve this so, but we have, if you want to apply the full Fourier transform you need from  $X$  belongs to minus infinity to infinity, so I extend this  $Y(x)$  from  $X$ , from 0 to infinity to minus infinity to infinity, so how do I do this? So although  $Y$  is actually,  $Y$  is if you restrict to 0 to infinity it is this solution, otherwise it is as though it is extended from minus infinity to infinity.

Then what is the equation now? So equation now is  $D^2 Y/DX^2$  and  $DY/DX + 2Y$  where  $Y(x)$  is here, and then this is equal to now I have  $E^{-X}$ , when  $X$  is positive that is  $X$  is positive, and what I do is I take 0 when  $X$  is negative, those are equal to 0, this is actually same as saying  $E^{-X}$  times  $H(x)$ , so this is how if I take that extension, because then on the negative side it's already  $Y(0)$ , so  $Y(0)$  is actually 0, and  $Y'(0)$  is equal to 0, so suppose these two are conditions are given at this point, okay.

Now if you take  $X$  less than 0, less than side negative side what happens, because these two initial conditions your equation is  $Y'' + 3Y' + 2Y = 0$ , so have a homogeneous equation with homogeneous boundary conditions which are homogeneous initial conditions that are given the solution is actually completely 0 for every  $X$  in minus infinity to 0, so if you choose these conditions so and your equation, because your equation and the negative side is 0 you have completely negative side for all  $X$ , solution  $Y(x)$  is already there, the way you choose your initial conditions that makes it  $Y(x)$  is actually 0,  $Y(x)$  is 0 for every  $X$  less than or equal to 0, that's clear, okay, the solution is actually, solution is this, because of the initial conditions.

Example: Solve  $\frac{d^2 y}{dx^2} + 3 \frac{dy}{dx} + 2y = e^{-x}$ ,  $x > 0$ .  $y(0) = 0 = y'(0)$ .  $x \in (-\infty, \infty)$ .

Solution: Extend  $y(x)$ ,  $x \in (-\infty, \infty)$ .

Equation now is  $\frac{d^2 y}{dx^2} + 3 \frac{dy}{dx} + 2y = \begin{cases} e^{-x}, & x > 0 \\ 0, & x \leq 0 \end{cases} = e^{-x} H(x)$

Solution is  $y(x) = 0$ ,  $\forall x \leq 0$ .

Now only thing you have to worry about  $X$  positive side that is what we chose  $X$  positive is  $E^{-X}$ , so as such so this is at how crazy you look at only negative side and at  $X = 0$  these conditions are satisfied,  $Y(x)$  is actually completely 0, so these conditions are already utilized the negative side, so that way now you consider what happens for  $X$  belongs to minus infinity to infinity if you look at it, this is  $E^{-X}$  times  $H(x)$ , so whenever you have these 0 boundary conditions you can extend it this way with Heaviside function so that your solution negative set is always 0, okay.

And then, so the initial conditions are anyway satisfied okay, these conditions are already utilized that sense, okay. Now if we apply for this full equation, if you apply Fourier transform and so

what is that apply, if you apply? D square Fourier transform of Y dash if I write D square Y/DX square as Y double dash Fourier transform of xi + 3 times DY/DX that is Y dash(xi), cap of xi + 2 times Y cap(xi) equal to, you have E power -X H(x) this cap of xi, that's what you have to choose, so if you calculate this one so what is this Fourier transform of 1/root 2 pi, so right hand side what we need is 1/root 2, Fourier transform is 1/root 2 pi E power -X H(x), H(x) is a negative side is 0, so 0 to infinity is 1 and you have E power - I xi X DX so what you get is 1 over 1 + I xi, if you and 1/root 2 pi is a constant, and so E power -X times 1 + I xi, okay, so of course minus is there, so if you apply 0 to infinity this is actually equal to 1/root 2 pi 1 over 1 + I xi, so the inverse transform of this is actually E power - X H(x), if you are given like this you can easily see the inverse transform as E power -X H(x), so here because it's a derivative if you take the Fourier transform what it comes out is I xi square for 2 derivatives into Y cap(xi), it's a property of Fourier transform and here E power 3 times I xi times, Y cap(xi) and here 2 Y cap(xi), so Y cap(xi) is common herein all places, so you have this equal to here you can write 1/root 2 pi, 1/1 + I xi.

So what is your Y cap(xi)? It is 1/root 2 pi, 1/1 + I xi into 1 divided by, I have I xi square and it's like if I put I xi as X square + 3X + 2, so you have (X+1)(X+2) you can write this, so if you write like that you have I xi + 1 I xi + 2, so this if you write it as a partial fractions, so let me write this as a partial fractions if you write -1/1 + I xi + 1/1 + I xi whole square + 1/1 +, rather 2 + I xi, so this is what is after partial fractions.

So now you can invert it Y cap, if you invert your Y cap, take the inverse Fourier transform that will become Y(x) which is equal to the integral, Fourier integral theorem and then if you do here so for this if you apply Fourier integral theorem what you see is you can easily see, for this inverse is E power -X H(x) so minus of E power -X H(x) and here +, and this will be so if you have a square, square what you do is you try to get this Fourier transform of E power -X times H(x) for which you multiply X, for this full transform if you multiply X any X power K and if I choose this as a function, F(x) this is actually equal to, if you take it as a property you can prove

Transform Techniques for Engineers 2 - Windows Journal

Soln is  $y(x) = 0, \forall x \leq 0$  ✓

$$\hat{y}''(\xi) + 3\hat{y}'(\xi) + 2\hat{y}(\xi) = \widehat{e^{-x} H(x)}(\xi)$$

$$[(i\xi)^2 + 3(i\xi) + 2]\hat{y}(\xi) = \frac{1}{\sqrt{2\pi}} \frac{1}{1+i\xi}$$

$$\hat{y}(\xi) = \frac{1}{\sqrt{2\pi}} \left[ \frac{1}{1+i\xi} \cdot \frac{1}{(i\xi+1)(i\xi+2)} \right]$$

$$= \frac{1}{\sqrt{2\pi}} \left[ -\frac{1}{1+i\xi} + \frac{1}{(1+i\xi)^2} + \frac{1}{2+i\xi} \right]$$

$$\Rightarrow y(x) = -e^{-x} H(x) +$$

Ans =  $\frac{1}{\sqrt{2\pi}} \int_0^{\infty} e^{-x} e^{-i\xi x} dx = \frac{1}{\sqrt{2\pi}} \left. \frac{-e^{-x(1+i\xi)}}{-(1+i\xi)} \right|_0^{\infty} = \frac{1}{\sqrt{2\pi}} \frac{1}{1+i\xi}$

$x^r + 3x^{r-1} + 2x^{r-2} = \frac{1}{(x+1)(x+2)}$

$$\widehat{x^k f(x)}(\xi) = \frac{1}{\sqrt{2\pi}} \frac{1}{(1+i\xi)^{k+1}} \hat{f}(\xi)$$

it, this is you can actually show that this is equal to what you get is  $1/\sqrt{2\pi} \cdot 1/(1+i\xi)^{k+1}$  times  $F(\xi)$ , no something else you will get so apart you get, no, no, no, not this way so what you get is  $F(\xi) \cdot 1/(1+i\xi)^{k+1}$  you get, that's what you will get, okay.

Transform Techniques for Engineers 2 - Windows Journal

Soln is  $y(x) = 0, \forall x \leq 0$  ✓

$$\hat{y}''(\xi) + 3\hat{y}'(\xi) + 2\hat{y}(\xi) = \widehat{e^{-x} H(x)}(\xi)$$

$$[(i\xi)^2 + 3(i\xi) + 2]\hat{y}(\xi) = \frac{1}{\sqrt{2\pi}} \frac{1}{1+i\xi}$$

$$\hat{y}(\xi) = \frac{1}{\sqrt{2\pi}} \left[ \frac{1}{1+i\xi} \cdot \frac{1}{(i\xi+1)(i\xi+2)} \right]$$

$$= \frac{1}{\sqrt{2\pi}} \left[ -\frac{1}{1+i\xi} + \frac{1}{(1+i\xi)^2} + \frac{1}{2+i\xi} \right]$$

$$\Rightarrow y(x) = -e^{-x} H(x) +$$

Ans =  $\frac{1}{\sqrt{2\pi}} \int_0^{\infty} e^{-x} e^{-i\xi x} dx = \frac{1}{\sqrt{2\pi}} \left. \frac{-e^{-x(1+i\xi)}}{-(1+i\xi)} \right|_0^{\infty} = \frac{1}{\sqrt{2\pi}} \frac{1}{1+i\xi}$

$x^r + 3x^{r-1} + 2x^{r-2} = \frac{1}{(x+1)(x+2)}$

$$\widehat{x^k f(x)}(\xi) = \frac{1}{\sqrt{2\pi}} (\hat{f}(\xi))^{k+1}$$

So can we see this one? If you do simply for  $K=1$   $F(x) \cdot \text{cap of } (x)$  if you do this  $1/\sqrt{2\pi} \int_{-\infty}^{\infty} F(x) e^{-i\xi x} dx$ , so I try to take this as, so integral value of this may be so you can just if I substitute this easier, so if you take  $E^{-x} H(x)$  if you take this is actually equal to  $1/(1+i\xi)^{k+1}$ , so this is at least this you can take off so for every  $K$  belongs to the natural numbers, okay, so we choose this, so if you do  $F$  as this  $E^{-x} H(x)$  then what you get if you replace, this is going to be  $E^{-x}$ , and this is going to be 0,

so once you have this, this is equal to 1 over root 2 pi and you have E power -X, so what you get is -E power -X + I xi divided by 1 + I xi that is the integration, and you multiply into X you substitute the limits, because of X this is 0 and you have a minus, minus minus plus now 1/root 2 pi minus, so 0 to infinity you have E power -X times 1 + I xi / 1 + I xi into derivative of X is 1, so we have DX, so this is actually equal to 1/root 2 pi and you see again so 1/1 + I xi comes out and this integral as you can see here so that is going to be 1, one more 1/1 + I xi, so there's a square, so you can easily see that this is the, just by inspection you can see that if it is a

The screenshot shows a software window titled "Transform Techniques for Engineers 2 - Windows Journal" with a toolbar at the top. The main area contains handwritten mathematical work:

- At the top left, the differential equation is written:  $\hat{y}''(\xi) + 3\hat{y}'(\xi) + 2\hat{y}(\xi) = \widehat{x^k e^{-x} H(x)}(\xi)$ .
- Below it, the transformed equation is shown:  $[(i\xi)^2 + 3(i\xi) + 2]\hat{y}(\xi) = \frac{1}{\sqrt{2\pi}} \frac{1}{1+i\xi}$ .
- The solution for  $\hat{y}(\xi)$  is derived as:  $\hat{y}(\xi) = \frac{1}{\sqrt{2\pi}} \left[ \frac{1}{1+i\xi} \cdot \frac{1}{(i\xi+1)(i\xi+2)} \right]$ .
- This is further simplified to:  $= \frac{1}{\sqrt{2\pi}} \left[ -\frac{1}{1+i\xi} + \frac{1}{(1+i\xi)^2} + \frac{1}{2+i\xi} \right]$ .
- The final result is:  $\Rightarrow y(x) = -e^{-x} H(x) +$

On the right side of the page, there are additional notes and formulas:

- A boxed formula:  $\widehat{x^k e^{-x} H(x)}(\xi) = \frac{1}{\sqrt{2\pi}} \frac{1}{(1+i\xi)^{k+1}}, \forall k \in \mathbb{N}$ .
- A formula for the Fourier transform of  $x^k e^{-x} H(x)$ :  $\widehat{x^k e^{-x} H(x)}(\xi) = \frac{1}{\sqrt{2\pi}} \int_0^{\infty} x^k e^{-x} e^{-i\xi x} dx$ .
- A partial derivation of the integral:  $= \frac{1}{\sqrt{2\pi}} \left[ \frac{-e^{-x(1+i\xi)}}{(1+i\xi)} x \right]_0^{\infty} + \frac{1}{\sqrt{2\pi}} \int_0^{\infty} \frac{e^{-x(1+i\xi)}}{(1+i\xi)} dx$ .
- The final result for the integral:  $= \frac{1}{\sqrt{2\pi}} \frac{1}{(1+i\xi)^2}$ .

something, something if you know already the square of this kind of you, instead of replacing this with some function F if you know how to evaluate so that it's Fourier transform and then what you end up is power of Fourier transform of such functions power K+1, so this is what you see. So you can easily see here that this is going to be E power -X H(x) times X so you have X times this and here this one E power -2X H(x) this is X belongs to -infinity to infinity, okay. So what happens when Y(x)=0 clearly so the solution is actually, you can easily see here X is less than or equal to 0, so once you have this one Y(0) is automatically satisfied, Y dash(0) so that is the reason if you are given these zero initial conditions you always extend your right hand side function with Heaviside function for which you have the Fourier transform you know how to evaluate and what happens at Y(x) positive, Y(x) = E power -X + X E power -X + E power -2X, 4X positive, so this is your solution and this is a negative side, how that? And now even if you use this one because let us see whether if it is continuous or not, Y(0) is actually equal to, so as you see is that this is the differential equation so what you're looking for is the solution Y that has derivatives, okay, right hand side is kind of forcing both the X positive and X negative side, one side is anyway these conditions are satisfied, the other side also you can

transform techniques for engineers 2 - windows journal

Solution: extend  $y(x)$ ,  $x \in (-\infty, \infty)$   $y(0) = 0 = y'(0)$   $\forall x \in \mathbb{R}$

Equation now is  $\frac{dy}{dx} + 3\frac{dy}{dx} + 2y = \begin{cases} e^{-x}, & x > 0 \\ 0, & x \leq 0 \end{cases} = e^{-x} H(x), \quad x \in (-\infty, \infty)$

---

Solution is  $y(x) = 0, \quad \forall x \leq 0$  ✓

$$\hat{y}''(\xi) + 3\hat{y}'(\xi) + 2\hat{y}(\xi) = \widehat{e^{-x} H(x)}(\xi)$$

$$[(i\xi)^2 + 3(i\xi) + 2]\hat{y}(\xi) = \frac{1}{\sqrt{2\pi}} \frac{1}{1+i\xi}$$

$$\hat{y}(\xi) = \frac{1}{\sqrt{2\pi}} \left[ \frac{1}{1+i\xi} \cdot \frac{1}{(i\xi+1)(i\xi+2)} \right]$$

$$= \frac{1}{\sqrt{2\pi}} \left[ -\frac{1}{1+i\xi} + \frac{1}{(1+i\xi)^2} + \frac{1}{2+i\xi} \right]$$

$\widehat{x^k e^{-x} H(x)}(\xi) = \frac{1}{\sqrt{2\pi}} \frac{1}{(1+i\xi)^{k+1}}, \quad \forall k \in \mathbb{N}$

$$\widehat{x^k e^{-x} H(x)}(\xi) = \frac{1}{\sqrt{2\pi}} \int_0^{\infty} x^k e^{-x} e^{-i\xi x} dx$$

$$= \frac{1}{\sqrt{2\pi}} \int_0^{\infty} \frac{e^{-x(1+i\xi)}}{(1+i\xi)^{k+1}} dx + \frac{1}{\sqrt{2\pi}} \int_0^{\infty} \frac{e^{-x(1+i\xi)}}{(1+i\xi)^{k+1}} dx$$

$$= \frac{1}{\sqrt{2\pi}} \frac{1}{(1+i\xi)^{k+1}}$$

easily see the condition that if you put  $Y_0$  this is going to be  $-1 + 1$  which is 0, and  $Y'(x)$  is  $E$  power  $-X$   $E$  power  $-X + E$  power  $-X - 2E$  power  $-2X$ , so if you put  $X=0, Y'(0)$  is  $1 + 1 - 2$ , this is also 0, so these conditions are automatically satisfied because  $Y$  is a continuous function, the solution that you calculated is a continuous function, okay.

Transform Techniques for Engineers 2 - Windows Journal

$$= \frac{1}{\sqrt{2\pi}} \left[ -\frac{1}{1+i\xi} + \frac{1}{(1+i\xi)^2} + \frac{1}{2+i\xi} \right]$$

$$\Rightarrow y(x) = -e^{-x} H(x) + x e^{-x} H(x) + e^{-2x} H(x), \quad x \in (-\infty, \infty)$$

$y(x) = 0, \quad x \leq 0$   
 $y(0) = 0 = y'(0)$  ✓

$y(x) = -e^{-x} + x e^{-x} + e^{-2x}, \quad x > 0$   
 $y(0) = -1 + 1 = 0, \quad y'(0) = e^{-1} - 1 + e^{-2} = 1 - 1 = 0$  ✓

$$\widehat{x^k e^{-x} H(x)}(\xi) = \frac{1}{\sqrt{2\pi}} \int_0^{\infty} \frac{e^{-x(1+i\xi)}}{(1+i\xi)^{k+1}} dx + \frac{1}{\sqrt{2\pi}} \int_0^{\infty} \frac{e^{-x(1+i\xi)}}{(1+i\xi)^{k+1}} dx$$

$$= \frac{1}{\sqrt{2\pi}} \frac{1}{(1+i\xi)^{k+1}}$$

So this is what you're looking for is the solution that automatically satisfies these boundary conditions. So and this is not the only way to prove, to solve this equation, you can also solve this equation because the domain is the only positive side you can apply cosine transform or sine transform directly and you can, there you don't have to worry directly these coefficients will

come into the picture so those things whatever may be the value when it is nonzero you can use cosine and sine transforms only when these both the conditions are 0 you can use the direct Fourier transform by extending with Heaviside function, okay.

We will see some more example in this direction, maybe later on we will try to solve these problems with cosine and sine transform, so let's do some more problems for example let me use one more example, one more example is  $Y'' - 4Y' + 4Y = Xe^{-x}$  into  $E$  power  $-X$ ,  $X$  positive and  $Y(0)$  is 0 which is  $Y'(0)$ , if you are given like this so solution as usual you can proceed because it is zero boundary condition you can extend this to full real line okay, so with Heaviside function, so you extend  $Y(x)$ ,  $X$  belongs to minus infinity to infinity, okay, so you have a solution equation is now  $4Y'' + 4Y = Xe^{-x} H(x)$ , now  $H$  belongs to minus infinity to infinity.

Now your conditions are automatically satisfied as you see negative side is always at that point is 0, it's a homogenous equation then negative side the solution is actually you know that homogenous equation with 0 initial conditions is always 0, completely identically 0,  $Y(x) = 0$  for  $X$  negative, so these conditions are automatically satisfied for this equation because at  $X$  equal to 0 it's completely 0, so your  $X = 0$  also it's given 0.

So let us see what happens, so let us solve we are not solving by splitting it like that, and we will try to solve this together as though this is one function okay, we don't split the domains and do this, even if you split you can see that this one you clearly see that these conditions are automatically satisfied, and negative side at  $X = 0$ .

So now look at as usual, apply the full Fourier transform you see that  $\int_{-\infty}^{\infty} x^2 Y(\xi) d\xi - 4 \int_{-\infty}^{\infty} i\xi Y(\xi) d\xi + 4 \int_{-\infty}^{\infty} Y(\xi) d\xi$  and here is a Fourier transform of this you have seen earlier that this is  $1 / (1 + i\xi)^2$ , okay, so if you apply this one  $X^2$  so if you look at this one, this is  $Y(\xi) = 1 / (1 + i\xi)^2$ , this is when you do, when you get this you see that  $1 / \sqrt{2\pi}$ , so you have  $1 / \sqrt{2\pi}$  missing, and what you get is  $1 / \sqrt{2\pi} (1 + i\xi)^{-2}$  and here  $1 / (1 + i\xi)^2$  that is like  $X^2 - 4X + 4$  that is

going to be  $(x-2)^2$  whole square, right,  $(x-2)^2$  whole square that is  $x^2 - 4x + 4$ , so that is what is the left hand side, so this is what you have.

Now if you use the partial fractions  $1/\sqrt{\pi}$ , if you use the partial fractions I write directly here, so what I do is first  $1/(1+i x)$  you have something divided by  $1+i x$  is something some number into  $1/(1+i x)^2$  + something this is here,  $2 - R/(x-2)$ ,  $(x-2)^2$  + what is divided by  $(x-2)^2$  whole square, so if you make this as some numbers A, B, C, D and you can

Example: solve  $y'' - 4y' + 4y = x e^{-x}$ ,  $x > 0$ .  
 $y(0) = 0 = y'(0)$ .

Sol: Extend:  $y(x)$ ,  $x \in (-\infty, \infty)$

$$y'' - 4y' + 4y = x e^{-x} H(x), \quad x \in (-\infty, \infty)$$

$$(i\omega)^2 \hat{y}(\omega) - 4(i\omega) \hat{y}(\omega) + 4 \hat{y}(\omega) = \frac{1}{\sqrt{\pi}} \frac{1}{(1+i\omega)^2}$$

$$\hat{y}(\omega) = \frac{1}{\sqrt{\pi}} \frac{1}{(1+i\omega)^2} \frac{1}{(i\omega-2)^2}$$

$$= \frac{1}{\sqrt{\pi}} \left[ \frac{A}{1+i\omega} + \frac{B}{(1+i\omega)^2} + \frac{C}{(i\omega-2)} + \frac{D}{(i\omega-2)^2} \right]$$

multiply and then we can see we can equate the coefficients of, by partial fraction method you can find I'll write directly it is going to be  $2/27$  you can verify this and it's going to be  $1/9$  and this is going to be  $-2/27$  and this is  $1/9$ , okay, so this is exactly our  $Y(x)$ , if you invert this a first term will give me  $2/27 e^{-x} H(x)$  and  $+1/9 e^{-x} H(x)$  and here it's going to be  $-2/27$  and this is going to be  $e^{2x} H(x)$  because of  $-2$ , okay, if you calculate this Fourier transform you will see that it's going to be this one, and this one will be  $+1/9 x e^{2x} H(x)$ , and where is this valid? From  $-\infty$  to  $\infty$ , so if you look at negative side it's completely 0 that is what we get, and for positive side that is what we want which is equal to  $2/27 e^{-x} + 1/9 x e^{-x} - 2/27 e^{2x} + 1/9 x e^{2x}$ , this is for  $x$  positive side that is what we want.

Now if you verify this  $Y(0) = 2/7$  and  $-2/7$  that is 0, clearly  $Y'(x)$  if you calculate  $2/27 e^{-x}$  with  $-1$  and here  $+1/9 e^{-x} - 1/9 x e^{-x} - 2/27 \times 2 e^{2x} + 1/9 e^{2x} + 2/9 x e^{2x}$ . Now this if you put  $x=0$ , okay, so what you get is  $Y'(0) = -2/27$  and you have  $+1/9$  and here  $-4/27$  and you have  $1/9$ , and this is actually same as 0 again, so  $-6/27$  that is  $-2/9$  already you have  $1/9$ ,  $1/9$  that's  $2/9$ , this is 0, so both the conditions are satisfied this is what we verified, okay, so the actual solution what we are looking for even

Transform Techniques for Engineers 2 - Windows Journal

$$\hat{y}(z) = \frac{1}{\sqrt{\pi}} \frac{1}{(1+iz)^2} \frac{1}{(iz-2)^2}$$

$$\hat{y}(z) = \frac{1}{\sqrt{\pi}} \left[ \frac{\frac{1}{27}}{1+iz} + \frac{1/9}{(1+iz)^2} + \frac{-\frac{2}{27}}{(iz-2)} + \frac{1/9}{(iz-2)^2} \right]$$

---

$$y(x) = \frac{2}{27} e^{-x} H(x) + \frac{1}{9} x e^{-x} H(x) - \frac{2}{27} e^{2x} H(x) + \frac{1}{9} x e^{2x} H(x), \quad x \in (-\infty, \infty)$$

$$y(x) = \frac{2}{27} e^{-x} + \frac{1}{9} x e^{-x} - \frac{2}{27} e^{2x} + \frac{1}{9} x e^{2x}, \quad x > 0$$

Verification

$$\left\{ \begin{array}{l} y(0) = 0, \quad y'(x) = -\frac{2}{27} e^{-x} + \frac{1}{9} e^{-x} - \frac{1}{9} x e^{-x} - \frac{2}{27} e^{2x} + \frac{1}{9} e^{2x} + \frac{2}{9} x e^{2x} \\ y'(0) = -\frac{2}{27} + \frac{1}{9} - \frac{4}{27} + \frac{1}{9} = -\frac{6}{27} + \frac{2}{9} = 0 \end{array} \right.$$

if you solve by other methods you should get you're getting this, this is your solution of that initial value problem that is given as here.

If we solve also by cosine transform or sine transform because it's given in the semi-infinite domain so you can solve even by those methods, that we will see later, okay. So let us solve one more example but this is not that straightforward this is let's do this solve  $Y'' - 4Y = 1$  now, so this is  $X$  positive, so a solution we know already what is its solution and so the conditions are also same given as 0,  $Y$  and its derivatives at  $X = 0$  okay, so if you do this what is so if you have, if you follow the same way then moment you see these initial conditions you can extend this, extend to  $X$  belongs to  $-\infty$  to  $\infty$  together the equation  $Y'' - 4Y = H(x)$ , now this is  $X$  belongs to  $-\infty$  to  $\infty$ .

Example: Solve  $y'' - 4y' + 5y = 1, x > 0$   
 $y(0) = 0 = y'(0)$  ✓

Soln: Extend to  $x \in (-\infty, \infty)$  to get

---

$$y'' - 4y' + 5y = H(x), x \in (-\infty, \infty).$$

Again these conditions are automatically satisfied the negative side, is identically zero solution, so and what happens now? So what happens if you apply the Fourier transform like earlier  $\int_{-\infty}^{\infty} (x^2 - 4x + 5)Y(\omega) e^{i\omega x} dx$  it's a left-hand side, what is a Fourier transform of  $H(x)$  that is  $\int_{-\infty}^{\infty} H(x) e^{i\omega x} dx$  that is  $\int_{-\infty}^{\infty} \delta(x) e^{i\omega x} dx$  we have seen earlier that this is, this is not, this is actually what you get is with our definition  $\int_{-\infty}^{\infty} \delta(x) e^{i\omega x} dx = 1$  so this is your Fourier transform so if I write this here  $\int_{-\infty}^{\infty} \delta(x) e^{i\omega x} dx = 1$  and then  $+ 1$  over  $\int_{-\infty}^{\infty} \delta(x) e^{i\omega x} dx$ , so what I do? What I get is  $Y(\omega)$  is, so  $Y(\omega)$  is now  $\int_{-\infty}^{\infty} \delta(x) e^{i\omega x} dx$  divided by, so what is this one?  $X^2 - 4X + 5$  this I can write like  $(X-2)^2 + 1$ , so what is this one? So if you get the roots of this equation you will see that roots of the equations are  $X = 2 + \sqrt{-1}$  or  $2 - \sqrt{-1}$ , so alright  $2 + \sqrt{-1}$  or  $2 - \sqrt{-1}$  divided by 2 so that is going to be this, these are the roots, so because of those are the roots so you can rewrite this as  $\frac{1}{(X-2)^2 + 1}$  for  $2 + \sqrt{-1}$  and other one is  $2 - \sqrt{-1}$  this is one term, other term if we write like this  $\frac{1}{(X-2)^2 + 1}$  over the same, this division the left hand side  $\int_{-\infty}^{\infty} \delta(x) e^{i\omega x} dx = 1$ , and  $\int_{-\infty}^{\infty} \delta(x) e^{i\omega x} dx = 1$ , so this is what you have, so if you try to take the Fourier transform, so before you take the Fourier transform so what happens here? So this is going to be  $\int_{-\infty}^{\infty} \delta(x) e^{i\omega x} dx$ , this you write

Transform Techniques for Engineers 2 - Windows Journal

Soln: Extend to  $x \in (-\infty, \infty)$  to get

$$y'' - 4y' + 5y = H(x), \quad x \in (-\infty, \infty).$$

$$\hat{y}(z) = \sqrt{\frac{\pi}{2}} \delta(z) + \frac{1}{\sqrt{2\pi}} \frac{1}{iz}$$

$$z^2 - 4z + 5 = 0 \implies z = \frac{4 \pm \sqrt{16 - 20}}{2} = 2 \pm i$$

$$[(iz)^2 - 4(iz) + 5] \hat{y}(z) = \sqrt{\frac{\pi}{2}} \delta(z) + \frac{1}{\sqrt{2\pi}} \frac{1}{iz}$$

$$\hat{y}(z) = \sqrt{\frac{\pi}{2}} \frac{\delta(z)}{(iz - 2 - i)(iz - 2 + i)} + \frac{1}{\sqrt{2\pi}} \frac{1}{iz} \frac{1}{(iz - 2 - i)(iz - 2 + i)}$$

$$= \sqrt{\frac{\pi}{2}} \frac{\delta(z)}{(iz - 2 - i)(iz - 2 + i)} + \frac{1}{\sqrt{2\pi}} \left[ \frac{1/2}{iz} + \frac{1/(-2+i)}{iz - 2 - i} + \frac{1/(-2-i)}{iz - 2 + i} \right]$$

$$y(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} \sqrt{\frac{\pi}{2}} \frac{\delta(z)}{(iz - 2 - i)(iz - 2 + i)} e^{izx} dz + \frac{1}{5} \left( \dots \right)$$

And then here 1 over -2 + 4I times and this is going to be, so what do you get again like earlier you have E power because of this minus, and you will get a plus sign so you have 2 + I times, X times H(x) okay. And then one more, one more term is you have this partial fraction that coefficient -2 + 4I so minus minus comes out I put it here, and then what you have here is E

Transform Techniques for Engineers 2 - Windows Journal

$$[(iz)^2 - 4(iz) + 5] \hat{y}(z) = \sqrt{\frac{\pi}{2}} \delta(z) + \frac{1}{\sqrt{2\pi}} \frac{1}{iz}$$

$$z^2 - 4z + 5 = 0 \implies z = \frac{4 \pm \sqrt{16 - 20}}{2} = 2 \pm i$$

$$\hat{y}(z) = \sqrt{\frac{\pi}{2}} \frac{\delta(z)}{(iz - 2 - i)(iz - 2 + i)} + \frac{1}{\sqrt{2\pi}} \frac{1}{iz} \frac{1}{(iz - 2 - i)(iz - 2 + i)}$$

$$= \sqrt{\frac{\pi}{2}} \frac{\delta(z)}{(iz - 2 - i)(iz - 2 + i)} + \frac{1}{\sqrt{2\pi}} \left[ \frac{1/2}{iz} + \frac{1/(-2+i)}{iz - 2 - i} + \frac{1/(-2-i)}{iz - 2 + i} \right]$$

$$y(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} \sqrt{\frac{\pi}{2}} \frac{\delta(z)}{(iz - 2 - i)(iz - 2 + i)} e^{izx} dz + \frac{1}{5} \left( H(x) - \frac{1}{2} \right) + \frac{1}{(-2+i)} e^{(2-i)x} H(x) - \frac{1}{2+i} e^{(2-i)x} H(x), \quad x \in \mathbb{R}.$$

power 2 - IX times H(x) this is for H belongs to, X belongs to full real line that is minus infinity to infinity, so this is exactly your solution, so what happens to the first integral? Because of this delta function root pi root pi goes and you have root 2, both the place in the denominators you have 1/2 and when you put xi = 0 that is simply 1/2 - 1 - 2 - I times -2 + I so it's going to be 4, -2 whole

square 4 - I square, so it's going to be 5, so together 1/5 that is into 10 that is going to be 1/5 into 1/2 is 1/10, so the first integral is this.

And the second integral and this 1/4 and -1/2 that is going to be 0 so that is gone, and what you have is 1/5 H(x) + and this is what you have, so you have E power 2 + IX / -2 + 4I H(x) and 1 divided by 2 + 4I E power 2 - IX H(x), this is X belongs to minus infinity to infinity, so this gives me a solution as 1/5 for X negative, X positive side, X negative side is anyway 0 so because I have a 0 initial conditions with homogeneous equation you have YX is 0 completely, identically 0 solution in the negative side a positive side 1/5 + E power 2X is anyway common and divided by -2 +, so we maybe you have to see this one C power IX divided by -2 + 4I, then - E power -IX divided by 2 + 4I, right okay so this is for X positive side.

So we'll simplify this 1/5 + E power 2X, so I multiply -2 -4I multiply and divide so that you have E power IX times -2 -4I and the denominator you have a 4 + 16 that is 20, and here again I multiply 2 - 4I and the denominator, if you divide the same and you multiply with 2 + 4I that's going to be again 20, 4 + 16, 20, so as you see 1/5 + E power 2X is common and you can simplify this that 10 comes down and what you get is E power IX - 1 - 2I here E power -IX 1 - 2I,

Transform Techniques for Engineers 2 - Windows Journal

$$y(x) = \frac{1}{5} H(x) + \frac{e^{(2+i)x}}{-2+4i} H(x) - \frac{1}{2+4i} e^{(2-i)x} H(x), \quad x \in (-\infty, \infty).$$

---

$$\Rightarrow y(x) = \frac{1}{5} + e^{2x} \left[ \frac{e^{ix}}{-2+4i} - \frac{e^{-ix}}{2+4i} \right], \quad x > 0$$

$$= \frac{1}{5} + e^{2x} \left[ \frac{e^{ix}(-2-4i)}{20} - \frac{e^{-ix}(2-4i)}{20} \right]$$

$$= \frac{1}{5} + \frac{e^{2x}}{10} \left[ e^{ix}(-1-2i) - e^{-ix}(1-2i) \right]$$

64 / 102

so if take it out minus comes out this is going to be plus, and this is going to be plus, so this is going to be 1/5 times E power 2X/10, and this together is 2cos X so you have 5 cos X, and then here minus E power 2X/10 and you have E power IX - E power IX so you have 2I times E power IX - E power IX is, so you have again 2I sine X, so that makes it E power 2X/5 cos X and here so this 2 is 5 so you have this is going to be +I square is -1 so that makes it plus, you have E power 2X sine X 2E power 2X divided by 5, so this is what you have as your solution.

Transform Techniques for Engineers 2 - Windows Journal

$$\Rightarrow y(x) = \frac{1}{5} + e^{2x} \left[ \frac{e^{ix}}{-2+4i} - \frac{e^{-ix}}{2+4i} \right], \quad x > 0$$

$$= \frac{1}{5} + e^{2x} \left[ \frac{e^{ix}(-2-4i)}{20} - \frac{e^{-ix}(2-4i)}{20} \right]$$

$$= \frac{1}{5} - \frac{e^{2x}}{10} \left[ e^{ix}(1+2i) + e^{-ix}(1-2i) \right]$$

$$= \frac{1}{5} - \frac{e^{2x}}{5} \cos x - \frac{e^{2x}}{5} \cdot 2i \sin x$$

$$y(x) = \frac{1}{5} - \frac{e^{2x}}{5} \cos x + \frac{2}{5} e^{2x} \sin x, \quad x > 0.$$

64 / 102

So your YX is this solution, okay, so as you can see when you substitute Y at 0, cos 0 is 1 so you have 1/5 - 1/5 that is 0, this term is 0 so it's clearly Y(0) is 0 and if you calculate Y dash (x) which is, this is if we differentiate this this 0 and here you have sine X E power 2X/5 and here are -2 E power 2X cos X/5, again if you do differentiate this term so 2/5 cos X E power 2X and this gets cancelled anyway, so and then if we differentiate this part we have 4/5 E power 2X sine X.

Now if you substitute Y dash(0) here, this term is 0 because of sine X and because of sine X that is 0, so you have Y at 0 is 0, and Y dash(0) is also 0, so these two are verified, okay.

Transform Techniques for Engineers 2 - Windows Journal

$$\Rightarrow y(x) = \frac{1}{5} + e^{2x} \left[ \frac{e^{ix}}{-2+4i} - \frac{e^{-ix}}{2+4i} \right], \quad x > 0$$

$$= \frac{1}{5} + e^{2x} \left[ \frac{e^{ix}(-2-4i)}{20} - \frac{e^{-ix}(2-4i)}{20} \right]$$

$$= \frac{1}{5} - \frac{e^{2x}}{10} \left[ e^{ix}(1+2i) + e^{-ix}(1-2i) \right]$$

$$= \frac{1}{5} - \frac{e^{2x}}{5} \cos x - \frac{e^{2x}}{5} \cdot 2i \sin x$$

$$y(x) = \frac{1}{5} - \frac{e^{2x}}{5} \cos x + \frac{2}{5} e^{2x} \sin x, \quad x > 0.$$

$$y(0) = 0, \quad y'(x) = \sin \frac{2x}{5} - \frac{2e^{2x}}{5} \cos x + \frac{2}{5} \cos x e^{2x} + \frac{4}{5} e^{2x} \sin x$$

$$y(0) = 0, \quad y'(0) = 0 \quad \parallel$$

64 / 102

So with this we can easily see that this even though 1 is not absolutely integrable function in this example, you can actually extend this as with Heaviside function, Heaviside function has a Fourier transform in terms of a delta function because these we see we are minimum by having we are doing the Fourier transform of very few generalized functions, usual functions anyway we know how to find Fourier transform, but generalized functions also that to only 1 or 2 which comes in the application, for example heavy side function are the delta function itself, only these two you see how to find the Fourier transform, we have already seen so make use of them to evaluate, to solve this simple ordinary differential equation okay with the initial data when it is a zero boundary, zero initial conditions you can solve that again, you're able to solve just by using the Fourier transform, full Fourier transform.

So you don't have to do this way, so you can also do all these problems using Fourier cosine transform or Fourier sine transform, because the domain is a same infinite that is between 0 to infinity, so these things we will see maybe in the next video. Thank you very much.
