Transform Techniques for Engineers

Application of Fourier Transforms to Differential and Integral Equations

Dr. Srinivasa Rao Manam
Department of Mathematics
IIT Madras

Welcome back, the last video we have seen how to solve ordinary differential equations with initial conditions using fully Fourier transform, we will try to solve this, so when you have those problems when we have 0 boundary kind, 0 initial conditions that means Y at 0 and Y dash at 0 is 0, if they are given and you can extend that when it is given the ordinary differential equation is given in the positive side that means 0 to infinity you can extend this to the minus infinity to infinity with right hand side by taking X positive anyway is given, and the negative side you make it 0 so that it will be in terms of Heaviside function for which you take that, you can take the full Fourier transform and try to invert after that you invert and get the solution. So this is possible if you have 0 initial conditions, if the conditions are not 0 at 0 that means initial conditions are not 0 conditions then you may have to, you cannot use this, these conditions are not automatically satisfied if you extend it as a Heaviside function in the right hand side. So in that case you may have to use Fourier sine transform or Fourier cosine transform, we will try to solve I'll just give you just for the sake of doing solving how to use this cosine and sine transform, any one of them you can use if your domain is 0 to infinity, so we'll just try to solve one or two problems on that in this video. So we'll consider this problem example, so let's take the same problems that we have solved but with nonzero conditions, let's do this one, so let's take Y double dash, so how do we solve this? Y double dash + $3Y$ dash + $2Y = E$ power $-X$, and X is positive, initial data is given as $Y(0)$ is 1, Y dash(0) = 2, so clearly this data is not 0, it's not 0 so you cannot extend this to given domain

is 0 to infinity you cannot extend this to minus infinity to infinity with the Heaviside function on the right and use the full Fourier transform we cannot do this because they're not 0 boundary conditions, so what we do is we try to apply a Fourier sine or cosine transform, so let's use any one of them, let's solve by Fourier cosine transform, okay, let's solve this by Fourier cosine transform, you can also use sine transform doesn't really matter, so if you use the Fourier transform so what you'll have the first term is $D^2 Y/DX^2$, X is positive, X is 0 to infinity, so if you apply the Fourier cosine transform on this, so F of FC of this which is, which becomes a function of ξ that is $\sqrt{2/\pi}$ that is a Fourier transform we have defined, Fourier cosine transform 0 to infinity $D^2 Y/DX^2 \cos \xi X DX$, do the integration by parts $\sqrt{2/\pi}$ you get $Y'(x)$ into $\cos \xi X$ right, so you bring this derivative over here so for that you differentiate, so do the integration by parts so you get 0 to infinity $Y'(x)$ and you have this ξ comes out, because of \cos , \cos derivative is $-\sin \xi X$ into ξ , so that ξ comes out and makes it negative sign becomes plus, this is DX . Clearly so you're looking for Y' and if you want to apply Fourier cosine transform Y has to be absolutely integrable function, okay, $Y(x)$ has to be absolutely integrable function from 0 to infinity that means $\lim_{x \rightarrow \infty} Y(x)$ has to be 0, as X goes to infinity has to be 0, it has to go to 0 at big values of X , so and Y and Y' 's derivatives, okay, you're applying for Y' also, Fourier cosine transform Y'' also, so in any case this Y' has to be 0 and \cos thing when you apply, so $-\sqrt{2/\pi}$ first term becomes the contribution will be $\cos 0$ is 1 and you have this $-$ sign, so you have $Y'(0)$ that we have as 2, so you have 2 times that $+\sqrt{2/\pi}$ ξ times again you apply Fourier integration by parts here, if you do this you have $Y(x)$ $\sin \xi X$ and

Example: Solve $y'' + 3y' + 2y = e^{-x}$, $x > 0$.
 $y(0) = 1$, $y'(0) = 2$.

Soln: Let us solve this by Fourier cosine transform.

$$F_c \left(\frac{d^2 y}{dx^2} \right) (\xi) = \sqrt{\frac{2}{\pi}} \int_0^{\infty} \frac{d^2 y}{dx^2} \cos \xi x dx$$

$$= \sqrt{\frac{2}{\pi}} \left[y(x) \cos \xi x \Big|_0^{\infty} + \xi \int_0^{\infty} y(x) \sin \xi x dx \right]$$

$$= -\sqrt{\frac{2}{\pi}} \cdot 2 + \sqrt{\frac{2}{\pi}} \xi \left[y(x) \sin \xi x \Big|_0^{\infty} - \int_0^{\infty} y(x) dx \right]$$

$y(x)$
 ∞
 $\lim_{x \rightarrow \infty} y(x) = 0$

you have 0 to infinity and $-\xi$, ξ comes out, so one more ξ comes because of the derivative of sine, and we have ξ 0 to infinity, $Y(x) \cos \xi X DX$, so this is a Fourier cosine transform of Y , so what you have is $-2\sqrt{2/\pi} + \sqrt{2/\pi} \xi^2$ because this is 0 contribution $\sin \xi X$ at $\xi X = 0$, Y at infinity has to be 0, Y and Y' both, okay, so we use these conditions Y and Y' both are 0 at X goes to infinity, so this you have a minus and what you get is, what is left is this integral, this integral is with this coefficient is simply Fourier cosine transform of $Y(x)$ okay, so this is what you have for the first term.

Transform Techniques for Engineers 2 - Windows Journal

Example: Solve $y'' + 3y' + 2y = e^{-x}$, $x > 0$.
 $y(0) = 1$, $y'(0) = 2$.

Soln: Let us solve this by Fourier cosine transform.

$$F_c \left(\frac{dy}{dx} \right) (s) = \sqrt{\frac{2}{\pi}} \int_0^{\infty} \frac{dy}{dx} \cos sx \, dx$$

$$= \sqrt{\frac{2}{\pi}} \left[y(x) \cos sx \Big|_0^{\infty} + s \int_0^{\infty} y(x) \sin sx \, dx \right]$$

$$= -\sqrt{\frac{2}{\pi}} y(0) + \sqrt{\frac{2}{\pi}} s \int_0^{\infty} y(x) \sin sx \, dx$$

$$= -2\sqrt{\frac{2}{\pi}} - s F_c(y(x)) (s).$$

$$y(x)$$

$$\lim_{x \rightarrow \infty} y(x) = 0$$

Second term you do the sameway, so in second term if you do, if you apply for second term, so you try to apply, so I am just applying to the equation Fourier cosine transform then we get $-2\sqrt{2/\pi} - s$ Fourier cosine transform of $Y(x)$ $+ 3$ times Y dash, this is Y dash if you apply again same technique, instead of Y dash you have simply Y , if you have a Y dash here so one integration by parts will give me $Y(x) \cos xi X$, here you have $Y(x)$ here itself, so you can if you apply this Y at 0 so what you get is $-3\sqrt{2/\pi}$ and $\cos xi X$, so $\cos 0$ is 1, Y at 0 is 1, so that is 1, so this is what you get for this boundary term and here you get $+ xi$ times and that old root $2/\pi$ integral will become Fourier cosine transform of $Y(x)$ and xi , so this whole thing is the Fourier cosine transform and this is equal to this plus and you have one more term 2 times Fourier cosine transform of $Y(x)xi$, which is equal to E power $-X$ if you calculate Fourier cosine transform of E power $-X \cos xi X$, 0 to infinity root $2/\pi$ this is the Fourier cosine transform. And on the right it should have this integral also that value is 1 by, so if you can do the integration by part and solve it, so this is going to be root $2/\pi$ $1/1 + xi$ square, okay, that's what you have, so if you do this you get root $2/\pi$ 1 over $1 + xi$ square, so you have xi positive side this xi is Fourier cosine transform, so try to get what is your Fourier cosine transform of $Y(x)xi$, this coefficient of this is $-xi$ square, so you have 2 here, $2 - xi$ square and here you get $+xi$, $+xi$ and then this is equal to root $2/\pi$ $1/1 + xi$ square and this is going to be plus, so minus this is going to be $+5\sqrt{2/\pi}$, so $+5$ you can put it like this, so this is root $2/\pi$, so this is $5+$, so let's solve and do that in the next step, so this becomes Fourier cosine transform of $Y(x)$, this is root $2/\pi$ what you get is divided by $1 + xi$ square you have $5+$, so you have $6 + 5xi$ square that is the right hand side, and if you divide this side left hand side you have xi square, so you have a $-$ sign, and you have xi square $- xi - 2$, I think we made a mistake, so this 3 so when I applied 3

Transform Techniques for Engineers 2 - Windows Journal

$$= -\sqrt{\frac{2}{\pi}} \cdot 2 + \sqrt{\frac{2}{\pi}} \mathcal{F} \left[\cancel{y(x) \cos 3x} - \int_0^{\infty} y(x) \cos 2x \, dx \right]$$

$$= -2\sqrt{\frac{2}{\pi}} - \mathcal{F}_c(y(x))(2)$$

$$-2\sqrt{\frac{2}{\pi}} - \mathcal{F}_c(y(x))(2) - 3\sqrt{\frac{2}{\pi}} + 3\mathcal{F}_c(y(x))(3) + 2\mathcal{F}_c(y(x))(2) = \sqrt{\frac{2}{\pi}} \frac{1}{1+s^2}, \quad s > 0$$

$$\mathcal{F}_c(y(x))(s) (2 - s^2 + 3s) = \sqrt{\frac{2}{\pi}} \left(\frac{1}{1+s^2} + 5 \right),$$

$$\Rightarrow \mathcal{F}_c(y(x))(s) = -\sqrt{\frac{2}{\pi}} \frac{6+5s^2}{(1+s^2)} \cdot \frac{1}{s^2 - s - 2}$$

times Ydash, 3 times this and you have 3 xi, so I think that is a mistake I have, so you have 3 here, 3 missing for this second term, and you have this, you have 3xi, 3 xi, xi square - 3 xi, -2 yeah, so that's what you have, xi square - 3 xi - 2, so if we actually do this, do the partial fractions -root 2/pi, so partial fractions you can have for, one is so here what is left here is Fourier sine transform, okay, when I apply this one this is going to be Fourier sine transform this is, that is another mistake.

Transform Techniques for Engineers 2 - Windows Journal

$$= -2\sqrt{\frac{2}{\pi}} - \mathcal{F}_c(y(x))(2)$$

$$-2\sqrt{\frac{2}{\pi}} - \mathcal{F}_c(y(x))(2) - 3\sqrt{\frac{2}{\pi}} + 3\mathcal{F}_c(y(x))(3) + 2\mathcal{F}_c(y(x))(2) = \sqrt{\frac{2}{\pi}} \frac{1}{1+s^2}, \quad s > 0$$

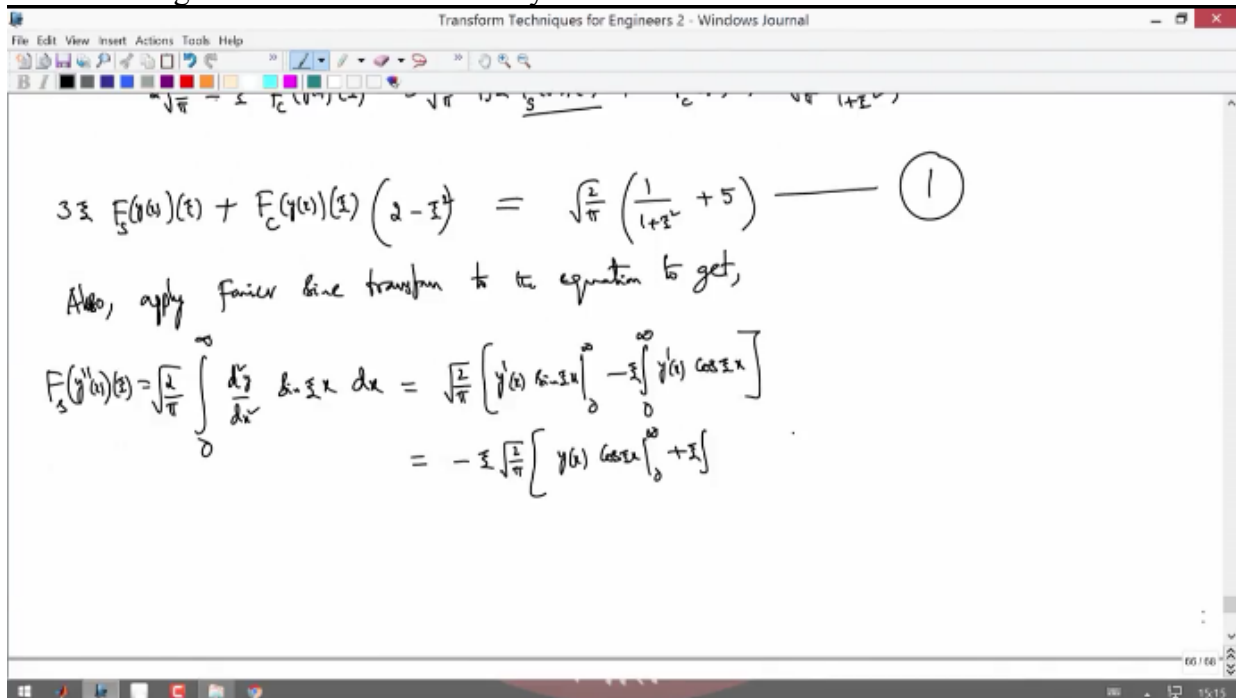

$$\mathcal{F}_c(y(x))(s) (2 - s^2 + 3s) = \sqrt{\frac{2}{\pi}} \left(\frac{1}{1+s^2} + 5 \right),$$

$$\Rightarrow \mathcal{F}_c(y(x))(s) = -\sqrt{\frac{2}{\pi}} \frac{6+5s^2}{(1+s^2)} \cdot \frac{1}{s^2 - 3s - 2}$$

$$= -\sqrt{\frac{2}{\pi}}$$

Fourier sine transform which you have, okay, so what you get is this one, this 2 - xi square times this + 3 times, 3 xi times Fourier sine transform of Y(x)(xi) + this is equal to this one, this is one equation, okay, so when you actually apply the Fourier cosine transform so that means you end

up with both Fourier sine and cosine transform, okay, so you cannot solve this equation directly so you need another, you can also apply Fourier sine transform for this and get one more equation like this, okay, so let's apply Fourier sine transform now, so basically if you want to solve this ODE with nonzero initial conditions you have to apply both the Fourier transform and Fourier sine transform get the two equations, solve for this Fourier cosine transform or Fourier sine transform and invert it you will get your $F(x)$, that is what exactly we need to do. So apply for Fourier sine transform again, so you apply not again so, also apply Fourier sine transform to the equation to get, what do you get if you apply? Fourier sine transform, so you have Fourier sine transform, what is this? Let's calculate, if you apply $Y''(x)$ square and you have Fourier sine transform is this, instead of cosine ξX , you have $\sin \xi X$ DX, this is your Fourier sine transform of $Y''(x)$ which is function of ξ , so this if you apply you get $\sqrt{2/\pi} Y'(x) \sin \xi X$ for which you apply 0 to infinity, and this is 0 because of sine, and you have $-\int_0^\infty \xi \cos \xi X dx$ because sine you differentiate with respect to X so you have $Y'(x) \sin$ becomes \cos , $\cos \xi X$, okay, so again if you apply so this is 0, so you have $-\xi$ of course you have $\sqrt{2/\pi}$, $\sqrt{2/\pi} \xi$ times, do one more time if you integration by parts $Y(x) \cos \xi X$, 0 to infinity you have $-\xi$ comes out this becomes $+$ after differentiating cosine function 0 to infinity.

Now you have $Y(x) \sin \xi X$ DX, so this is exactly so what you get is this is a $-$ sign, $-Y$ at 0, $-Y$ at 0 is given as 1, so 1 is minus minus plus ξ times $\sqrt{2/\pi}$ 0 at 0 is 1, okay, so that is what is this boundary terms, and this becomes ξ square $\sqrt{2/\pi}$ this is Fourier sine transform of $Y(x)$, which is function of ξ .

And then what happens to, now if you apply to the equation this Fourier sine transform you will see that if you apply you have $Y''(x)$ so that is this, so let me put this so $\xi \sqrt{2/\pi} - \xi$ square Fourier sine transform of $Y(x)$ of $\xi + 3$ times, now Y' dash, in the place of Y dash you have Fourier sine transform for Y' dash if we take, again instead of Y dash you have Y , so this will be you get, that's a minus sign because of this second term here, so $-\xi$ times Fourier sine transform of $Y(x)$ function of ξ , because this coefficient is 0, because of this boundary terms even with Y at X , and $\sin \xi X$ that is 0, and this is equal to right hand side Fourier

sinetransform of this will be xi divided by 1+ xi square root 2/pi xi dividedby 1 + xi square this is for thisintegral, so if you try to calculate thisintegral 2/pi 0 to infinity E power-X sine xi X DX is actually equalto 2/pi xi divided by 1 + xi square, okay, so that's how it is so 0, xi is0it's clearly you can see it 0.

B I [color palette]

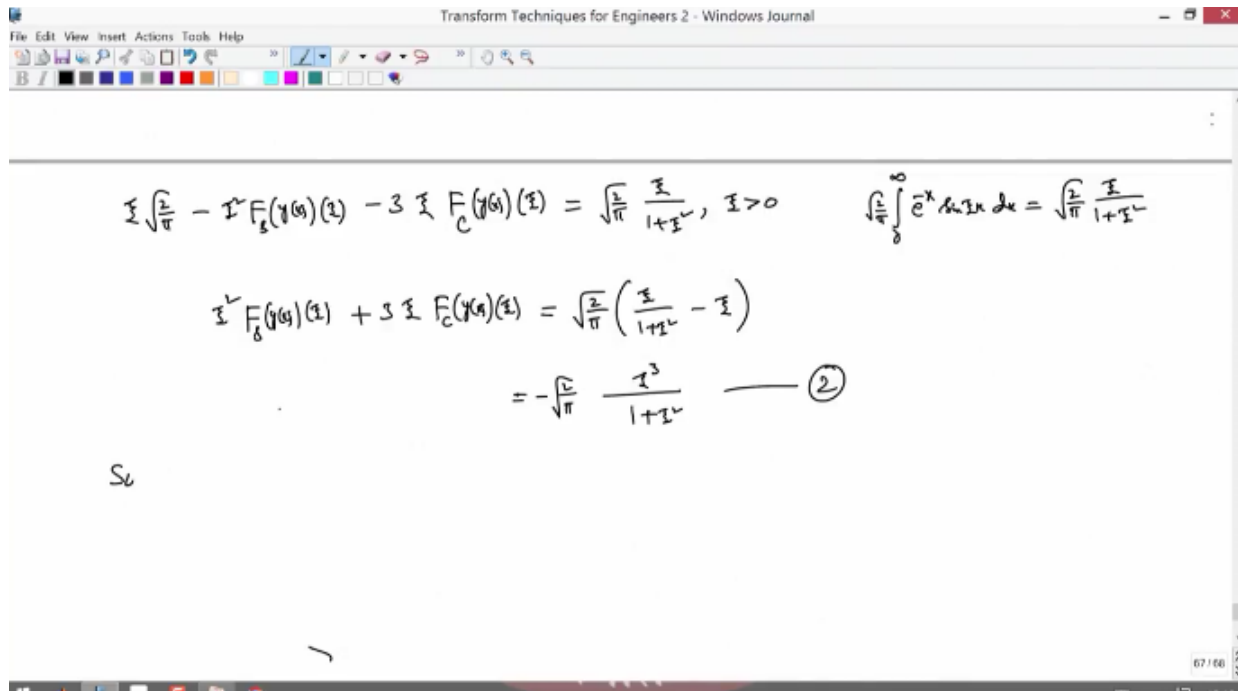

Also, apply

$$\begin{aligned}
 F_s(y''(x))(\xi) &= \sqrt{\frac{2}{\pi}} \int_0^{\infty} \frac{d^2 y}{dx^2} e^{-\xi x} dx = \sqrt{\frac{2}{\pi}} \left[y'(x) e^{-\xi x} \Big|_0^{\infty} - \xi \int_0^{\infty} y'(x) e^{-\xi x} dx \right] \\
 &= -\xi \sqrt{\frac{2}{\pi}} \left[y(x) e^{-\xi x} \Big|_0^{\infty} + \xi \int_0^{\infty} y(x) e^{-\xi x} dx \right] \\
 &= \xi \sqrt{\frac{2}{\pi}} - \xi^2 F_c(y(x))(\xi)
 \end{aligned}$$

$$\xi \sqrt{\frac{2}{\pi}} - \xi^2 F_c(y(x))(\xi) = 3 \xi F_s(y(x))(\xi) = \sqrt{\frac{2}{\pi}} \frac{\xi}{1+\xi^2} \qquad \sqrt{\frac{2}{\pi}} \int_0^{\infty} e^{-\xi x} e^{-\xi x} dx = \sqrt{\frac{2}{\pi}} \frac{\xi}{1+\xi^2}$$

67/68

So if you, so this is what you get from xi positive, now what happens to your, okay again I think I made a mistake what do you have here Fourier, if you apply the first one so for the third term this is not Fourier sine transform if you apply a Fourier sine transform for one derivative, one integration by parts will give me what you have is here this is cosine transform, Fourier cosine transform, so you have xi square Fourier sine transform of Y(x) xi + 3 xi, Fourier cosine transform of Y(x) which is function of xi, which is equal to root 2/pi, what you have is xi/xi square 1 + xi square here - xi, so which is 1 + xi square comes out, root 2/pi you have xi - xi - xi cube, so you have -xi cube. Right, yeah, so this is exactly what you have as a second equation, so you try to solve 1 and 2, so these are the linear equations for Fourier sine transform and cosine transform, okay.

Let's eliminate Fourier cosine both the equations 1 and 2, solve 1 and 2 for either sine FC $Y(x)$ of x or FS (YF) this is a transform for the function, unknown function $Y(x)$, okay, so if you do this you eliminate the FC you will get FS, FS will be let me write it directly, so your FS of $Y(x)$ as a function of ξ , this is equal to I'll directly write what you get, so you can just verify, you'll see that this is going to be if you solve it these two linear equations, you eliminate FC cosine and if you do that I'm directly writing, so if you do this you'll see that it's going to be $\sqrt{2/\pi}$, $\sqrt{2/\pi} \xi / (\xi^2 + 1)$, $\xi^2 + 4$, this is what you will get if you actually solve for Fourier sine transform, 1 and 2 you solve just get this Fourier FS, FS if you calculate this is what you get, this you try to write it as a partial fractions, if you write the partial fractions for this term this will be $3\xi / (1 + \xi^2)$, please verify this $1 + \xi^2$ whole square $- 2\xi$ divided by $\xi^2 + 4$, so this is what you'll get, so these things, now I know what exactly the inverse transform of this, because I know that I see that this is, this quantity is Fourier sine transform of E^{-x} , so if here if you do that, if you do this one now so Fourier transform if you take the inverse transform, take inverse transform of on both sides, inverse sine transform rather okay, sine on both sides to get, what you are getting? So left-hand side you will get the unknown function $Y(x)$, if you take the inverse transform you have $3 \times \sqrt{2/\pi} \xi / (1 + \xi^2)$ if there's a Fourier inverse transform that is going to be E^{-x} , the other one the second term so you have here again, okay so last term if you see, if you look at the last term that is going to be -2 again similar things $\xi^2 + 2$ square, so instead of 1 so if you actually see this integral E^{-x} if you use what I get is here I get $A / (A^2 + \xi^2)$, so this is what you have, so instead of A I have 2 now here, 2 square.

Transform Techniques for Engineers 2 - Windows Journal

Solve ① & ② for either $F_c(y(x))(s)$ or $F_s(y(x))(s)$.

$$F_s(y(x))(s) = \sqrt{\frac{2}{\pi}} \frac{5s - s^3}{(s^2+1)(s^2+4)}$$

$$= \sqrt{\frac{2}{\pi}} \left(\frac{3s}{1+s^2} + \frac{2s}{(1+s^2)^2} - \frac{2s}{s^2+4} \right)$$

Take inverse Laplace transform on both sides to get

$$y(x) = 3e^{-x} - 2e^{-2x} + xe^{-x}$$

And the third term, so you get Fourier inversion of this, I inverse Fourier, sine transform will give me $-2 \times \text{root } 2/\pi \times x/x^2 + 2$ square, that is E^{-2X} , and here because $1 + x^2$ square whole square you have so this will give me X into E^{-X} , okay, so that means it should be, I don't know really let me see X into E^X , what is the Fourier sine transform of that? Integral 0 to infinity $\text{root } 2/\pi \times X$ into $E^{-X} \sin xi X$ DX , so what is this? This is the inverse transform, right, so if you take the Fourier transform I should get back this, so this will give me $\text{root } 2/\pi$ so there's no way you will get this number 2, okay, but $X E^{-X}$ if you actually calculate as let's solve it you take the derivative of $X E^{-X}$ that is going to be $X - E^{-X}$ that's one derivative, other one is E^{-X} one more differentiate, if you differentiate this is going to be $X E^{-X}$ and you have $-E^{-X}$, $-E^{-X}$, and this is, this one + 3 times of this, this is a second derivative, and + 2 times of X into E^{-X} , what is this value, is this 0? 3, here you have 2, that's going to be 1, 1, 1, it's going to be, is it E^{-X} , $3E^{-X}$ and here you have, so it's E^{-X} , fine, 2, 3, 2 here 3 and -3 that is going to be 0, cancelled. So X into E^{-X} it's fine, so what you should be getting here is x divided by $1 + x^2$ square whole square, so the partial fractions, this 2 is not there, okay, so this corresponds to this one, so you have this, this is your general, this is the solution that satisfies the initial conditions Y at 0 is 1 and 2 these are used when you apply the Fourier cosine transform and Fourier sine transform.

Transform Techniques for Engineers 2 - Windows Journal

Take inverse Laplace transform on both sides to get

$$y(x) = 3e^{-x} - 2e^{-2x} + xe^{-x}$$

$$\frac{\sqrt{2}}{\pi} \int_0^{\infty} x e^{-x} \cos 2x \, dx = \frac{2}{(1+2^2)^2}$$

$$\begin{aligned} & \frac{3}{2} (-xe^{-x} + e^{-x}) + 2(xe^{-x}) \\ & + \cancel{x e^{-x} - e^{-x} - e^{-x}} \\ & = e^{-x} \end{aligned}$$

So if you directly solve by other methods you will get this solution, okay, it's just a confirmation, so I've calculated instead of calculating this as they do, so instead of, so if you calculate this, there's no way you will get this 2, so that means I've written wrong these partial fractions it should not be any 2 here, so you just verify, please verify that, so try to get the partial fractions you will see that they will get, you should get this form and so that you end up getting X power E power that you can easily put it in the equation and verify, that is exactly the

Transform Techniques for Engineers 2 - Windows Journal

$$F_s^{-1}(f(s)) = \sqrt{\frac{2}{\pi}} \frac{5s - s^3}{(s^2+1)(s^2+4)}$$

$$= \sqrt{\frac{2}{\pi}} \left(\frac{3s}{1+s^2} + \frac{s}{(1+s^2)^2} - \frac{2s}{s^2+4} \right)$$

Take inverse Laplace transform on both sides to get

$$y(x) = 3e^{-x} - 2e^{-2x} + xe^{-x}$$

$$\frac{\sqrt{2}}{\pi} \int_0^{\infty} x e^{-x} \cos 2x \, dx = \frac{2}{(1+2^2)^2}$$

$$\begin{aligned} & \frac{3}{2} (-xe^{-x} + e^{-x}) + \frac{2(xe^{-x})}{2} \\ & + \cancel{x e^{-x} - e^{-x} - e^{-x}} \\ & = e^{-x} \end{aligned}$$

equation, this is your Y dash, Y double dash, this is your 2Y dash, and this is your 3Y, right, this is your 2Y and this is your 3Y dash, which is actually equal to E power -X, so that means X into E power -X satisfies, they give an equation.

Transform Techniques for Engineers 2 - Windows Journal

Take inverse ^{and} transform on both sides to get

$$y(x) = 3e^{-x} - 2e^{-2x} + xe^{-x}$$

Initial C
Verified:

$$y(0) = 1, \quad y'(0) = -3e^{-x} + 4e^{-2x} - xe^{-x} + e^{-x} \Big|_{x=0}$$

$$= -3 + 4 + 1 = 2$$

$$\frac{\sqrt{\pi}}{2} \int_0^{\infty} xe^{-x} \cos sx \, dx = \frac{2}{(1+s)^2}$$

$$3 \frac{d}{ds} \left(\frac{-xe^{-x} + e^{-x}}{2} \right) + \frac{2(xe^{-x})}{2}$$

$$= \frac{e^{-x} \cdot 2}{2}$$

And now we can verify so Y at 0 is actually equal to 3-2 1, and when you put X = 0 that is 0, so Y dash at 0 also -3 power -X + 4 E power -2X + X E power -X, minus of this + E power -X if you put X = 0 here you'll see that -3 + 4 that is 0 + 1 so you have, that is also 0, that is 5 - 3 that's 2, that is exactly what we have the condition, so given conditions that it is Y at 0 is 1, and Y dash at 0 is 2 that is exactly what we got, they are verified okay, so these are verified, conditions are verified, initial conditions are verified, so this is how you solve, so given any ordinary differential equation you try to apply both Fourier cosine transform and sine transform, so if you apply, if you can apply if you have a 0 initial conditions you can extend this function to the domain to -infinity to infinity, and you can use only one transform that is full Fourier transform, otherwise if your domain is the only positive, and if your initial conditions are non-zero boundary condition, non-zero condition that is Y dash and Y0, Y at 0 and Y dash at 0 if they are non-zero you cannot extend as a Heaviside function and make use of the full Fourier transform, so you don't have choice but to use Fourier sine transform or cosine transform that are defined over for functions, absolutely integrable functions over, however the domain 0 to infinity. So if you apply one transform you will not be able to solve the equation, we will have to apply both sine and cosine transform and use the boundary conditions whatever initial conditions involved in the problem, you use inside this boundary terms when you do the integration by parts and you get two equations you solve them, either for Fourier sine transform or Fourier cosine transform and then you invert it you get back the same thing, so from these equations 1 and 2 either you solve for Fourier cosine transform or Fourier sine transform you will get, and then you invert it you will get your Y(x), so I have done for Fourier sine transform, I solved 1

Transform Techniques for Engineers 2 - Windows Journal

File Edit View Insert Actions Tools Help

$$-2\sqrt{\frac{2}{\pi}} - \xi F_c(y(x))(\xi) - 3\sqrt{\frac{2}{\pi}} + 3F_s(y(x))(\xi) + 2F_c(y(x))(\xi) = \sqrt{\frac{2}{\pi}} \frac{1}{1+\xi^2}, \quad \xi > 0$$

$$3F_s(y(x))(\xi) + F_c(y(x))(\xi) (2-\xi^4) = \sqrt{\frac{2}{\pi}} \left(\frac{1}{1+\xi^2} + 5 \right) \quad \text{--- (1)}$$

Also, apply Fourier sine transform to the equation to get,

$$F_s(y''(x))(\xi) = \sqrt{\frac{2}{\pi}} \int_0^{\infty} \frac{d^2}{dx^2} y(x) \sin \xi x \, dx = \sqrt{\frac{2}{\pi}} \left[y'(x) \cos \xi x \Big|_0^{\infty} - \xi \int_0^{\infty} y'(x) \cos \xi x \, dx \right]$$

$$= -\xi \sqrt{\frac{2}{\pi}} \left[y(x) \cos \xi x \Big|_0^{\infty} + \xi \int_0^{\infty} y(x) \sin \xi x \, dx \right]$$

$$= \xi \sqrt{\frac{2}{\pi}} - \xi^3 F_s(y(x))(\xi)$$

and 2 for FS, you can also try for solving eliminate YFS and try to get FC and you invert with Fourier cosine transform you may end up the same solution, so this is how we solve these ordinary differential equations with initial conditions, okay.

Transform Techniques for Engineers 2 - Windows Journal

File Edit View Insert Actions Tools Help

$$y(x) = 3e^{-x} - 2e^{-2x} + xe^{-x}$$

Initial conditions are verified: $y(0) = 1$, $y'(0) = -3e^0 + 4e^{-2 \cdot 0} - x e^{-x} + e^{-x} \Big|_{x=0} = -3 + 4 + 1 = 2$

$$\sqrt{\frac{2}{\pi}} \int_0^{\infty} x e^{-x} \sin \xi x \, dx = \frac{2}{(1+\xi^2)^2}$$

$$3 \int_0^{\infty} \frac{-x e^{-x} + e^{-x}}{2} + \frac{2(x e^{-x})}{2}$$

$$= \frac{e^{-x} y''}{2}$$

So this is one of the applications which we have, this is one of the applications of the Fourier transform that involves both full Fourier transform or Fourier cosine transform or Fourier sine transform.

So let's move on to some other applications you can also solve to certain type of integral equations, as I said an integral equation is so let me define now formally what is the integral equations, integral equations like differential equations, in the differential equations your

unknown function Y, so any function of X, Y its derivative Y dash = 0, this is called the differential equation because unknown function Y is under the derivative Y(x), right this is the meaning of Y dash.

So in your equation you have an unknown that is under this differential sign, derivative of this unknown function, integral equation is also you can think of function of X Y(x) and instead of derivative you have this integral, and your domain should be, can be anything, so some domain let us say I use A to B of Y(x), and if you want this to be function of X, so let's write Y(t) is an unknown, and some kernel, some function K(x,t) and you integrate under integral sign you have this unknown function, okay, this you should have so such equations are integral equations. Any function of this form is called an integral equation, so we can solve certain type of integral equations, linear integral equations that means the term, this term without Y, linear means you put Y, so Y should be you only Y terms not Y square or any higher Y's, let me put it, so this is a linear equation, so as usually the definition so it involves only Y and integral, under the integral only Y, Y(t) not Y square kind of thing totally. If you formally mathematically if you can write instead of Y you put Y1 + CY2, in the place of Y you should get back F(x,y1) under this integral sign Y1(t) whatever okay, so this plus C times, C comes out again same instead of Y you have Y2 integral A to B, Y2(t) K(XT, DT) okay, so that has to be 0. So in integral equation + for Y1, + C times integral equation for CY2 that is what you should get for F(x,y) integral A to B, Y(t), K(xt,dt).

Integral equation for Y, you should be able to split, if your Y is in this form you should be able to write it as integral equation for Y1 + C times integral equation for Y2, then that is called that

Transform Techniques for Engineers 2 - Windows Journal

$$y(x) = 3e^x - 2e^{-x} + xe^x$$

$$y'(x) = -3e^x + 4e^{-x} - xe^x + e^x$$

$$= -3 + 4 + 1 = 2$$

$$\int_0^{\sqrt{\pi}} xe^{-x} dx = \frac{1}{(1+x)^2}$$

$$3y' + \frac{(-xe^x + e^{-x})^3}{x^2 - e^{-x} - e^{-x}} + \frac{2(xe^x)}{2y}$$

$$= e^{-x} y''$$

Linear Integral equations:

$$F\left(x, y(x), \int_a^b y(t)K(x,t) dt\right) = 0$$

$$F(x, y_1 + cy_2) = F(x, y_1) + cF(x, y_2)$$

such equations are linear integral equations, so you can solve certain type of linear integral equations, let me write exactly what kind of form of linear equations you can solve, so I will remove this general integral equation, so let me briefly give you what kind of equations you can solve, so you have Y(x), let's say, so let's choose some A(x) it's a given function plus under this integral sign let's choose from A to B, A to B means you can also extend because we know let's say let's take from -infinity to infinity, so that we can use the full Fourier transform, Y(t) here some K(x,t), okay and DT this is equal to F(x), so X belongs to -infinity to infinity, if it is

like this you can apply your Fourier transform okay, so if you apply you can divide both sides if $F(x)$ is non-zero you can apply, so you can write like this, so you can apply both sides say $A(x)$ will, you can write it here, you can absorb it here by $A(x)$, you call whatever here as F mu $F(x)$, so here $K(x,t)$ divided by X Smu $K(x,t)$, so your typical equation can be in this form or you can remove this and keep it like this, that is also you can, that is also called linear equation, okay. So different type of linear equations, so this A I'll put constant let us say some constant L where L is either 0 or 1, if it is 0 it is a, it's a first kind of equation, if it is 1 is the second kind of equation because outside this integral you have an unknown, if it is there you call the second kind of equation of one type, and if $L = 0$ this is first kind equation, so these are type of equations which you have, so what kind of equations we can solve is when the kernel, this K is called kernel, this $K(x,t)$ if you want to apply Fourier transform here, this should be this kind of convolution function, convolution integral, so the convolution means $K(x,t)$ should be $K(x-t)$, so it should be in this form, then I can apply both sides Fourier transform, for example if I apply Fourier transform, if I have this then what if you apply a Fourier transform Y cap (ξ) for the first term + here, if you apply Fourier transform, Fourier transform if you apply we know that this is a convolution form $Y(t)$ into $K(x,t)$ is Fourier transform of this convolution, okay. This is convolution integral, so Fourier transform will be Y cap (ξ) into K cap (ξ) , alright, so this is what you get in the left hand side, the right hand side you have F xi (ξ) , so you can easily write Y cap (ξ) as F cap (ξ) divided by $1 + \sqrt{2\pi}$ into K cap (ξ) , so from this if you take both sides inverse Fourier transform you can get your function $F(x)$, that is satisfying this integral equation, $Y(x)$ as Fourier integral Fourier transform, Fourier integration of, inverse Fourier transform of F cap (ξ) this is an integral which you have to evaluate, if you really want form of solution want, so this is actually you know already that $1/\sqrt{2\pi}$ integral $-\infty$ to ∞ , F xi E power $i x$ X D xi, so this is function of X because you're integrating with respect to ξ , ξ will go, so this is the exactly the way that you want, that is the unknown function that satisfies this integral equation, this is how you solve this linear integral equations, we will try to give you some examples, let's give some example.

Transform Techniques for Engineers 2 - Windows Journal

File Edit View Insert Actions Tools Help

$y(x) = 3e^{-x} - 2e^{-2x} + xe^{-x}$

Initial conditions are verified: $y(0) = 1$, $y'(0) = -3e^{-x} + 4e^{-2x} - xe^{-x} + e^{-x}$
 $= -3 + 4 + 1 = 2$

$\int_0^{\infty} x e^{-x} \cos x dx = \frac{1}{(1+x)^2}$

$3 \int \frac{(-xe^{-x} + e^{-x})^2 + 2(xe^{-x})}{+ xe^{-x} - e^{-x} - e^{-x}}$
 $= \underline{e^{-x} y''}$

Linear Integral equations:

$y(x) + \int_{-\infty}^{\infty} y(t) k(x,t) dt = f(x), x \in (-\infty, \infty)$

If $k(x,t) = k(x-t)$, then

$\hat{y}(\xi) + \sqrt{2\pi} \hat{y}(\xi) \cdot \hat{k}(\xi) = \hat{f}(\xi)$

$\Rightarrow \hat{y}(\xi) = \frac{\hat{f}(\xi)}{1 + \sqrt{2\pi} \hat{k}(\xi)} \Rightarrow y(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} \frac{\hat{f}(\xi)}{1 + \sqrt{2\pi} \hat{k}(\xi)} e^{i\xi x} d\xi$

Let's do some example now, solve $\int_{-\infty}^{\infty} |x-t|^{-1/2} y(t) dt = f(x)$, $x \in (-\infty, \infty)$, how do we solve this? So I don't have, this is a linear equation because only Y 's are there, there is no way square kind of thing and your kernel is in the form of $X^{-1/2}$, so I can solve this by Fourier transform method, by solution, by transform method, by applying Fourier transform because the domain is full space, if your domain is only 0 to ∞ you can apply Fourier sine transform depends, okay, Fourier transform we get, what we get, the left hand side so you have $\sqrt{2\pi} \text{mod } X^{-1/2}$ for which you take the Fourier transform whatever you get, okay, that's function of ξ times $\hat{Y}(\xi)$ this is because left hand side is basically convolution of, because why is this so? Because this is actually convolution of $\text{mod } X^{-1/2}$ convolving with $Y(x)$ for which if you take the Fourier transform this is exactly what you have, Fourier transform of F convolution G is $\sqrt{2\pi}$ times convolution of this, transform of first function and transform of second function that is exactly you have by the property of the Fourier transform. Now this is your left hand side, the right hand side is simply Fourier transform of F , so what you get? You need looking for Y as a solution, so you try to $Y(\xi)$ as $F(\xi)$ divided by $\sqrt{2\pi} \text{mod } X^{-1/2}$ Fourier transform of this, so if we actually calculate that, so you need to calculate what is $1/\sqrt{2\pi}$ Fourier transform of, right, so what is this one? So you calculate $\text{mod } X^{-1/2}$ Fourier transform of ξ , what is this one? By definition $1/\sqrt{2\pi} \int_{-\infty}^{\infty} |x|^{-1/2} e^{-i\xi x} dx$, so this you need to find to proceed here, to put it here and then try to get the inverse transform for this one, so if you apply

The image shows a handwritten derivation on a whiteboard or paper. At the top, it says "Example. Solve $\int_{-\infty}^{\infty} |x-t|^{-1/2} y(t) dt = f(x)$, $x \in (-\infty, \infty)$ ". Below this, it says "Soln: By Applying Fourier transform, we get". The derivation proceeds as follows:

$$\widehat{|x|^{-1/2} * y(x)}(\xi) = \sqrt{2\pi} \widehat{|x|^{-1/2}}(\xi) \cdot \hat{y}(\xi) = \hat{f}(\xi)$$

$$\Rightarrow \hat{y}(\xi) = \frac{\hat{f}(\xi)}{\sqrt{2\pi} \widehat{|x|^{-1/2}}(\xi)}$$

$$\Rightarrow y(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} \frac{\hat{f}(\xi)}{\sqrt{2\pi} \widehat{|x|^{-1/2}}(\xi)} e^{i\xi x} d\xi$$

To the right of these equations, there is a calculation for the Fourier transform of $|x|^{-1/2}$:

$$\widehat{|x|^{-1/2}}(\xi) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} |x|^{-1/2} e^{-i\xi x} dx.$$

The derivation is written in black ink on a white background, with some corrections and underlines. The top of the page shows a window title "Mathematical techniques for Engineers 2 - windows journal" and a standard toolbar.

this finally if you take the inverse transform here $1/\sqrt{2\pi} \int_{-\infty}^{\infty} \hat{F}(\xi) \text{mod } X^{-1/2} d\xi$, after getting this you put it here $\text{mod } X^{-1/2}$ which is a function of ξ , $E^{i\xi x} d\xi$, this is exactly the solution, okay.

Transform Techniques for Engineers 2 - Windows Journal

Example: Solve $\int_{-\infty}^{\infty} |x-t| y(t) dt = f(x), \quad x \in (-\infty, \infty)$

Sol: By applying Fourier transform, we get

$$\widehat{|x|^{-1/2} * y}(z) = \sqrt{2\pi} \widehat{|x|^{-1/2}}(z) \cdot \hat{y}(z) = \hat{f}(z)$$

$$\Rightarrow \hat{y}(z) = \frac{\hat{f}(z)}{\sqrt{2\pi} \widehat{|x|^{-1/2}}(z)}$$

$$\Rightarrow y(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} \frac{\hat{f}(z)}{\sqrt{2\pi} \widehat{|x|^{-1/2}}(z)} e^{izx} dz$$

$$\widehat{|x|^{-1/2}}(z) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} |x|^{-1/2} e^{-izx} dx$$

So you try to get this and put it here, you try to get this and put it here and you can evaluate what is that you get, if you actually see this so maybe we have not done this earlier, so maybe these things we'll see in the next video how to calculate this part, and then we'll put it here and try to evaluate, how we can evaluate such interiors, and also so basically so that tells you that see if I try to substitute, try to get this part and put it here and this is, we need to, we can try to evaluate this transform this integral, this integral we can try to evaluate, so again we use certain properties of Fourier, certain properties of the Fourier transform to evaluate such integrals, so that is again so we use the same properties, so you have the convolution if you have a product of 2 such transform which you know, so root 2 pi times Fourier transform of something into Fourier transform of something, suppose you have 2 such functions you know already, then inverse transform of this is simply, inverse transform of this, this is actually inverse transform of this function here, what you have is here? This is the inverse transform of this function, so if this function is what you have is here, you can write like root 2 pi, I mean 2 functions, product of 2 functions into root 2 pi inverse transform of this will be simply convolution function of this function, inverse transform of this and inverse transform of this, that's what that is the property we use, okay.

Transform Techniques for Engineers 2 - Windows Journal

Example: Solve $\int_{-\infty}^{\infty} |x-t| y(t) dt = f(x), \quad x \in (-\infty, \infty)$

Sol: By applying Fourier transform, we get

$$\widehat{|x|^{-1/2} * y}(z) = \sqrt{2\pi} \widehat{|x|^{-1/2}}(z) \cdot \hat{y}(z) = \hat{f}(z)$$

$$\Rightarrow \hat{y}(z) = \frac{\hat{f}(z)}{\sqrt{2\pi} \widehat{|x|^{-1/2}}(z)}$$

$$\Rightarrow y(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} \frac{\hat{f}(z)}{\sqrt{2\pi} \widehat{|x|^{-1/2}}(z)} e^{izx} dz$$

$$\widehat{|x|^{-1/2}}(z) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} |x|^{-1/2} e^{-izx} dx$$

So convolution function transform, something like if I write F convolution of G(x) Fourier transform you take root 2 pi because without definition this root 2 pi comes out, F cap(xi) times G cap(xi) this if you take the Fourier transform, if you take the inverse transform if i write like inverse cap okay, and if you apply here this inversion will cancel this Fourier transform, so you end up getting this, so what is the sign means? This is actually 1/2 pi by definition 1/root 2 pi okay, root 2 pi so integral -infinity to infinity, so this root 2 pi this root 2 pi goes E power this times E power I xi X D xi okay, so this is exactly what you have, so you can use this once you have this convolution you apply Fourier transform and it's inverse transform. so you can see that convolution you can write a product of Fourier transform of F and G and with the exponential function if you integrate that is exactly what you get, so such property if we use here to evaluate this in the next video, okay.

Transform Techniques for Engineers 2 - Windows Journal

Example. Solve $\int_{-\infty}^{\infty} |x-t| y(t) dt = f(x), \quad x \in (-\infty, \infty)$

Soln: By applying Fourier transform, we get

$$\widehat{|x|^{-1/2} * y}(z) = \sqrt{2\pi} \widehat{|x|^{-1/2}}(z) \cdot \hat{y}(z) = \hat{f}(z)$$

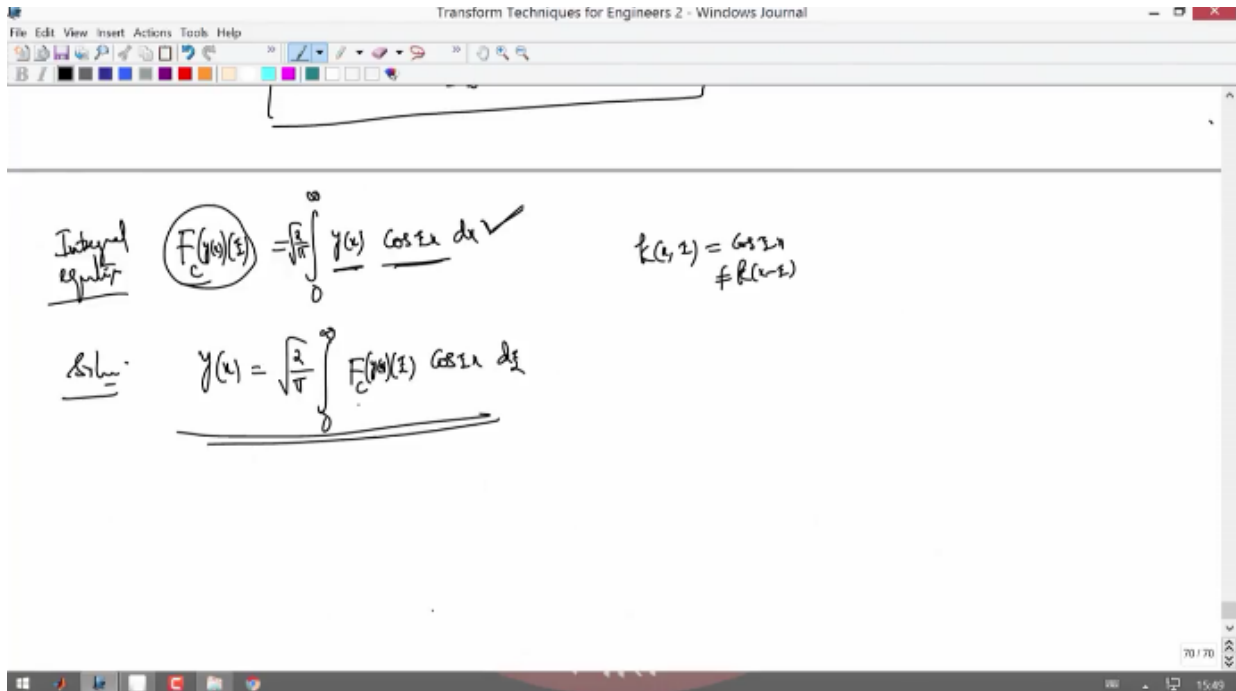

$$\Rightarrow \hat{y}(z) = \frac{\hat{f}(z)}{\sqrt{2\pi} \widehat{|x|^{-1/2}}(z)}$$

$$\Rightarrow y(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} \frac{\hat{f}(z)}{\sqrt{2\pi} \widehat{|x|^{-1/2}}(z)} e^{izx} dz$$

$$\widehat{|x|^{-1/2}}(z) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} |x|^{-1/2} e^{-izx} dx$$

$$f * g(x) = \int_{-\infty}^{\infty} \hat{f}(z) \cdot \hat{g}(z) e^{izx} dz$$

So we'll see that this is one such application of Fourier transform where the domain is -infinity to infinity, and we can use full Fourier transform and also another, so this is a restricted, only certain integral equations you can solve when the kernel is of $K(x,t) = x-t$ form that is it's already that integral, the integral equation, the integral term it should be like convolution type of integral, so that we can apply the Fourier transform you can apply that, you can apply the property of the Fourier transform on the convolution of 2 functions, and then you can get your Fourier transform of the unknown function, and you invert it you can get back your solution, so this is how you can solve, so we have already have such integral equations, for example Fourier cosine transform $Y(x)$ if you have, what is the Fourier cosine transform? Fourier cosine transform of Y is $\cos xi \int_0^{\infty} Y(x) dx$, this is from 0 to infinity and we have $\sqrt{2/\pi}$ as your Y cap of, this is Fourier cosine transform of $Y(x)$ which is function of xi , so if this is given if you know that Fourier cosine transform of xi this is given and you have $Y(x)$ is this, okay, otherwise let's write inverse transform, for this if you write the inverse transform again $\sqrt{2/\pi} \int_0^{\infty} \cos xi \cdot Y(x) dx$, so whichever is unknown, so each of these are integral equations for the unknowns $Y(x)$, here the unknown is Fourier cosine transform, if you have this if you know this one, and if you know this given that this is known, you can get this Fourier, if this is, if I give you this as some known function, then this is an integral equation with unknown as Y , you invert it you can get your solution, this is an integral equation, though it is whose kernel is not of the form which you choose $K(x,t)$ here $X \cos xi$ which is not of type $K(x-xi)$ though, okay, so but here these are the simplest those Fourier cosine transform of sine transform simplest, linear integral equations, okay, so here also just by inversion, the solution is we're not applying so if you apply here if you apply Fourier inverse transform here I'm just getting directly a solution, okay.

So here if you want this as an unknown, if this is an unknown so again same thing, okay, so if this is your integral equation you have a solution by inverse transform, inverse transform as a solution, is this a solution, so you have the solution for this integral equation though it is not in this form, not only such thing when K is of this form you can solve by earlier method otherwise also if it is simple cosine function or sine function, if it is a sine also same situation, so instead of cosine you have sine xz , so you can simply inverse transformation will give you the solution, these are simple linear integral equations, okay, simplest type Fourier transform and Fourier cosine transform and Fourier sine transform, these are simplest kind of integral equations, for example F again $F_c(x)$, this is a Fourier transform $1/\sqrt{2\pi}$ integral from $-\infty$ to ∞ $F(x) e^{-ix} dx$, this is an integral equation for unknown $F(x)$, okay. So what is its inverse? Inverse transform will give you the solution, inversion gives solution, what is the solution? $F(x)$, so inversion actually will give me $F(x) = 1/\sqrt{2\pi}$ integral from $-\infty$ to ∞ $F_c(x) e^{ix} dx$, as though this is given, if this is given this is an integral equation IE, integral equation for unknown $F(x)$, given that F_c is known, so if F_c is known this is known thing I'm putting here, and you know by inverse transform this is the case, this is your solution, okay, so you have an integral equation, you have a solution either it is, these are the simplest integral equations Fourier transform either cosine, sine, or full Fourier transform, these are all simplest

transform techniques for engineers 2 - windows journal

Integral equation $F_c(y(x)/z) = \int_0^{\infty} \frac{y(x)}{\cos zx} dx$ $k(x,z) = \frac{\cos zx}{\sin zx}$

Inverse transform $y(x) = \sqrt{\frac{2}{\pi}} \int_0^{\infty} F_c(y(x)/z) \cos zx dz$

I.E for $f(x) : \hat{f}(z) = \frac{1}{\sqrt{\pi}} \int_{-\infty}^{\infty} f(x) e^{-izx} dx$

Inversion giving solution $f(x) = \frac{1}{\sqrt{\pi}} \int_{-\infty}^{\infty} \hat{f}(z) e^{izx} dz$

integral equations for which you have solutions by the inverse transform, and if your kernel, integral equation, if kernel is of this form and $K(x,t)K(x-t)$ then the integral term will be convolution type of integral, when you apply the Fourier transform or Fourier cosine transform

Transform Techniques for Engineers 2 - Windows Journal

Linear Integral equations:

$$y(x) + \int_{-\infty}^{\infty} y(t) k(x,t) dt = f(x), \quad x \in (-\infty, \infty)$$

If $k(x,t) = k(x-t)$, i.e.

$$\hat{y}(z) + \sqrt{\pi} \hat{y}(z) \cdot \hat{k}(z) = \hat{f}(z)$$

$$\Rightarrow \hat{y}(z) = \frac{\hat{f}(z)}{1 + \sqrt{\pi} \hat{k}(z)} \Rightarrow y(x) = \frac{1}{\sqrt{\pi}} \int_{-\infty}^{\infty} \frac{\hat{f}(z)}{1 + \sqrt{\pi} \hat{k}(z)} e^{izx} dz$$

Example: Solve $\int_{-\infty}^{\infty} |x-t|^{-1/2} y(t) dt = f(x), \quad x \in (-\infty, \infty)$

Sol: By applying Fourier transform, we get

$$\widehat{|x|^{-1/2}}(z) = \frac{1}{\sqrt{\pi}} \int_{-\infty}^{\infty} |t|^{-1/2} e^{-itz} dt$$

you can write it as a product of a unknown, Fourier transform of the unknown, and the Fourier transform of the kernel.

So that you can get your unknown, Fourier transform of the unknown function you can write it as something known, and at the end you take the inverse transform to get the solution, only thing involved is how to evaluate such integrals of Fourier transforms, and when you take the inverse transform those integrals you have to evaluate to solve these integral equations, these are

the simplest application, so you can also solve some integral equations if it's in this form, okay, so this is another application where you can use these Fourier transforms, we will see as I said in this example, we will try to evaluate this integral in the next video, you may need some more Fourier transforms required, so for example this one, this Fourier transform you may require and then to avail it, to know what exactly is the solution, what exactly this integral you need to evaluate this Fourier transform of this, and then you have to see how to evaluate this using known transforms, okay. So we will see that in the next video. Thank you very much.
