Transform Techniques for Engineers

Evaluation of Integrals by Fourier Transforms

Dr. Srinivasa Rao Manam
Department of Mathematics
IIT Madras

Welcome back, in the last video we have seen how to solve some special linear integral equations using Fourier transform, we have done some examples how to find the solution of linear integral equation, and we did there, we have not finished the problems, so we'll just look into that and relevant some more problems on that, and we'll see, you also have seen how to find, so you can see that, we have seen that cosine Fourier transform and sine Fourier transform and usual full Fourier transform or some kind of integral equations if the right-hand side is given so inversion will give the solution, okay, that's what we have seen, we will see these kind of examples concerning these integral equations.

Transform Techniques for Engineers 2 - Windows Journal

Example: Solve $\int_{-\infty}^{\infty} |x-t|^{-1/2} y(t) dt = f(x); \quad x \in (-\infty, \infty) \checkmark$

Soln: By applying Fourier transform, we get

$$\widehat{|x|^{-1/2} * y(x)}(\xi) = \sqrt{2\pi} \widehat{|x|^{-1/2}}(\xi) \cdot \hat{y}(\xi) = \hat{f}(\xi)$$

$$\Rightarrow \hat{y}(\xi) = \frac{\hat{f}(\xi)}{\sqrt{2\pi} \widehat{|x|^{-1/2}}(\xi)}$$

$$\Rightarrow y(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} \frac{\hat{f}(\xi)}{\sqrt{2\pi} \widehat{|x|^{-1/2}}(\xi)} e^{i\xi x} d\xi$$

$$\widehat{|x|^{-1/2}}(\xi) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} |x|^{-1/2} e^{-i\xi x} dx$$

$$f * g(x) = \int_{-\infty}^{\infty} \hat{f}(\xi) \cdot \hat{g}(\xi) e^{i\xi x} d\xi$$

So to start with the example that we have started yesterday so this is the equation to solve, and then by applying, we applied the Fourier transform both sides so given integral, this is an integral equation, the integral term is a convolution product of $|x|^{-1/2}$ with Y , X for which if you take the Fourier transform this is by the property of the Fourier transform. A product of these two, so once you have this you can get your \hat{Y} cap, that is a Fourier transform of 1 on function Y , and which you see that this is this, F is given function, so \hat{F} cap is the Fourier transform of F , and if you do the inversion you will get this.

So in order to find, evaluate this integral we need to calculate this term, we will see how we do this, we need to calculate this Fourier transform of $|x|^{-1/2}$, so to do this we will just do the general, some other Fourier transform of some certain function and using the gamma function we will be able to find this Fourier transform of this, okay, so let's do that, and then come back to this and we'll substitute and try to get the inversion, so what I do is I try to find, so this little digression to do this, to find that thing we need to evaluate sine, so we'll consider, so evaluate this integral if you do this integral if you can evaluate $|x|^{-1/2}$ that is Fourier transform of $|x|^{-1/2}$, okay, evaluate Fourier transform of $|x|^{-1/2}$ for the cap which is a function of ξ , so this how do we do this? What I do is this is, you can see that this is actually this X , X is from 0 to infinity, so this is the integral over with this line, this is from 0 to infinity, and if you consider this as X -axis and Y -axis and you think of this quantity or you consider Fourier integral, sorry you consider this counterintegration we will try to evaluate over this closed interval within for the integral $F(z)$ is $Z^{-1/2}$ times $e^{-i\xi Z}$.

If you want to evaluate this $\int_{-\infty}^{\infty} |x|^{-1/2} e^{-i\xi x} dx$, because you are in the complex plane, this is your ω , so this is your ω inside, in that ω within this domain your function is analytic which is differentiable function because it's exponential and a polynomial, so you need to find this ω because this is analytic including this line and this circular curve, and this line so this has to be, this is integral over this ω by Cauchy theorem this is actually equal to 0 , okay. Then because you see that this, if you calculate this one you parameterize this curve, you parameterize this curve and you parameterize this curve, and if you do the parameterization

over this curve what happens is that Z is R times $E^{i\theta}$, R is fixed θ is between 0 to $\pi/2$, so if you do that DZ will be $iR E^{i\theta} d\theta$, okay, so if you evaluate this over this circular arc CR the integral contribution will be $\int_0^{\pi/2} (R e^{i\theta})^{n-1} iR E^{i\theta} d\theta$, okay, and then $E^{-i\theta}$, R is, x is anyway real number, so Z is R times $E^{i\theta}$, DZ is again $iR E^{i\theta} d\theta$, so this is the integral on this contribution, so you can easily see this quantity is a bounded thing if you look at this quantity what happens to this, as R goes to infinity, okay, so as R goes to infinity this is the polynomial this is exponential function $E^{i\theta}$ this is, if you look at this $E^{i\theta}$ is $\cos \theta + i \sin \theta$ so what you get is

Digression: Evaluate $\hat{z}^{n-1} = \int_0^{\infty} z^{n-1} e^{-iz} dz$

$\int_{CR} f(z) dz = \int_0^{\pi/2} R^{n-1} e^{-iRz} dt = 0$

$z = R e^{i\theta}, 0 \leq \theta \leq \pi/2$

$\int_0^{\pi/2} \frac{R^{n-1} e^{i\theta} e^{-iR R e^{i\theta}} i R e^{i\theta} d\theta}{e}$

that I and this $-I$ becomes, so what you have to do is this one $E^{i\theta}$, $I \theta$ is this here you look at $\cos \theta$ into $E^{i\theta}$, you need to get I^2 is -1 that is going to be plus, so you consider here is plus so that I get $E^{i\theta}$ $-I x R \cos \theta$, so you have I here that is plus, and $E^{i\theta}$ I this, and then $-x R \sin \theta$, okay, θ is between 0 to $\pi/2$, so as R goes to infinity this quantity is going to 0 , even whatever you multiply with R^{n-1} doesn't matter because R power, this is a polynomial into exponential function always goes to 0 , so that way the contribution over this is 0 , so if you look at this one, if you look at the parameterization for this that is this integral, and if you look at this one whatever is left that means this is equal to, so its integral over this to 0 to I infinity, okay, so if you actually redo it so this is, so that is how

Diagram: Evaluate $\int_0^{\infty} x^{n-1} e^{-ix} dx$ ✓

$$\int_{\partial\Omega} f(z) dz = \int_0^{\infty} x^{n-1} e^{-ix} dx + \int_{\text{arc}} z^{n-1} e^{-iz} dz + \int_{\text{imag axis}} z^{n-1} e^{-iz} dz = 0$$

$$z = re^{i\theta}, \quad 0 \leq \theta \leq \pi/2$$

$$dz = ire^{i\theta} d\theta$$

$$\int_0^{\pi/2} \frac{r^{n-1} e^{i(n-1)\theta} e^{-ir e^{i\theta}} ire^{i\theta} d\theta}{e^{i(n-1)\theta} (e^{-ir \cos\theta} - i r \sin\theta)} \rightarrow 0$$

7/1/08

you can see that integral over 0 to infinity is same as integral over 0 to I infinity or rather over this line, or over the Y-axis your integral value, so that is same as saying if I consider I xi X as some T, some variable T if we consider like this and what you get is ID xi DX is DT, so both if you, by complex variable method so both are same so you will see that if you calculate over this so this integral over this that means this integral is same as integral over this line is exactly what I am going to write here, so by just substituting this variable I xi X with a new variable T if you do this, this integral value if you call this I the integral value X power N-1 E power -I xi X D xi, DX this is equal to, so this is and you substitute this I xi, so what you get in the place of X, you get T/I xi power N-1, and E power -T, DT is so you need to put DX that is DT/I xi, okay, and this is 0 to infinity.

So this is exactly what you get if you directly put it, so 0 to infinity along Y-axis, okay, so if you do this one so here also if you do the parameterization this is X is 0 + Y is I times Y, Y is between 0 to infinity something like this, so you do the same thing, if you do this substitution also you'll get the same thing, along the Y axis or along this Y axis we actually have to write I times 0 into I times infinity, in the complex plane I infinity or -I infinity anything is actually only one infinity, so anything, there's nothing like -infinity or +infinity in a complex plane, you write only as infinity, so in that sense or if you do directly here you will get the same thing so you will see that integral along this Y axis is actually this, or you simply put it in this way you will see that but you have to compromise somewhere that you see when you put X = 0, T is 0 when you put X = infinity, and this is I xi times infinity you cannot write, you don't write this I infinity this is in complex plane, I infinity is actually there's one infinity so that's going to be only infinity, so if you do this one this is your integral.

Now I use gamma function by rewriting, I just take -I, if I bring this I up -I/xi power N-1 I have one more here, so that comes out and 0 to infinity what you have is T power N-1 into E power -T DT this is exactly the definition of gamma function, gamma function is, gamma of N is actually definition is 0 to infinity, T power N-1 into E power -T DT, so if you do that so what I get is gamma N divided by xi power N times -I, -I I can write like E power I pi/2, I sine pi/2 that is -E power -I pi/2 is -I, so if you use this E power -I pi/2 power N so that is N pi/2, okay, so this

power N into this is a gamma anyway I've written, so this is gamma power, gamma of N divided by xi power N, this is E power -IN pi/2 that is a cos I can rewrite like cos N pi/2 and then -I sine N pi/2, so this is actually your integral.

Let $z = t$
 $dz = dt$

$$\int_0^{\infty} t^{n-1} e^{-t} dt = \int_0^{\infty} \left(\frac{t}{iz}\right)^{n-1} e^{-t} \frac{dt}{iz}$$

$$= \left(\frac{-i}{z}\right)^n \int_0^{\infty} t^{n-1} e^{-t} dt$$

$$= \frac{\Gamma(n)}{z^n} \left(e^{-i\pi/2}\right)^n$$

$$= \frac{\Gamma(n)}{z^n} \left(\cos \frac{n\pi}{2} - i \sin \frac{n\pi}{2}\right)$$

$0 + iy, 0 < y < \infty$

$$\Gamma(n) := \int_0^{\infty} t^{n-1} e^{-t} dt$$

$$(-i) = e^{-i\pi/2}$$

$$\int_{\partial\Omega} f(z) dz = \int_0^{\infty} z^{n-1} e^{-iz} dt = 0$$

$z = re^{i\theta}, 0 \leq \theta \leq \pi/2$

$$dt = i r e^{i\theta} d\theta$$

$$\int_0^{\pi/2} \frac{r^{n-1} e^{in\theta} e^{-iz} i r e^{i\theta} d\theta}{e^{i2n\theta} - i2n\theta}$$

As $r \rightarrow \infty, (e^{i2n\theta} - i2n\theta) \rightarrow 0$

So if I put $N = 1/2$ we know that gamma 1/2 is root pi okay, so root pi, so this is actually if you look at this Fourier transform, Fourier transform of, this is not Fourier transform this is actually kind of it's not, we're not doing it from minus infinity to infinity as a Fourier transform, so I don't write this as a Fourier transform, I'm just simply evaluating this integral so then you get this gamma 1/2 is this, so if you do this if we put N equal to this what you have is 0 to infinity X power N-1/2 is X power -1/2 power E -I xi X DX value = gamma 1/2 that is root pi/xi power 1/2 into cos N is 1/2, so pi/4 -I sine pi/4.

transform techniques for engineers - windows journal

$$= \left(-\frac{i}{2}\right)^n \int_0^{\infty} t^{n-1} e^{-t} dt$$

$$= \frac{\Gamma(n)}{2^n} \left(e^{-i\pi/2}\right)^n$$

$$= \frac{\Gamma(n)}{2^n} \left(\cos \frac{n\pi}{2} - i \sin \frac{n\pi}{2}\right)$$

$$n = \frac{1}{2}, \quad \Gamma\left(\frac{1}{2}\right) = \sqrt{\pi}$$

$(-i) = e^{-i\pi/2}$

$z = re^{i\theta}, \quad 0 \leq \theta \leq \pi/2$

$dt = ire^{i\theta} d\theta$

$$\int_0^{\pi/2} \frac{r^{n-1} e^{in\theta} ire^{i\theta} d\theta}{e^{i\lambda t} e^{i\lambda t}} \rightarrow 0$$

$$\int_0^{\infty} t^{-1/2} e^{-\xi t} dt = \frac{\sqrt{\pi}}{\xi^{1/2}} \left(\cos \frac{\pi}{4} - i \sin \frac{\pi}{4}\right)$$

So if you compare the coefficients real part and imaginary part if you equate what you get is, you can see that it's a E power -I xi X, so this is going to be cos xi X DX is actual equal to this cos pi/2 sine pi/2 is 1/root 2, 1/root 2, okay, so what you have is root pi/2 times xi power -1/2, okay, xi is positive, so you have to choose that xi is positive, so you have to evaluate that xi is positive, so as though you evaluated this way, this integral, so here you have xi is positive, and similarly if you compare the imaginary parts X power -1/2 sin xi X DX is equal to, it's also same xi power -1/2 xi is positive here again, so this is what you get this integral, so using this integral, so we'll just go back and try to write this how do you find this Fourier transform of this, you rewrite this as 1/root 2 pi, 1 is from 0 to infinity and when X is positive this is going to be X power minus, this mod X is X, X power -1/2 E power -I xi X DX this is what exactly, this integral we evaluated just now, and the other integral is 1/root 2 pi integral - infinity to 0, mod X when you have mod X, when X is negative this is -X power -1/2 and you have E power -I xi X DX, so mod X -1 power -1/2 that is 1 over -1 under root this is exactly 1/I, so you have 1/I times 1/X power 1/2 or X power -1/2, so you have -I times of this is exactly this one, so -X power -1/2 is and actually this one, okay, so this if you substitute so you see that is going to be -I and this I can replace this with this simply X power -1/2 these are the two integrals which you know now.

Transform Techniques for Engineers 2 - Windows Journal

Sol: By Applying Fourier transform, we get

$$\widehat{|x|^{-k} * y(x)}(\xi) = \sqrt{2\pi} \widehat{|x|^{-k}}(\xi) \cdot \hat{y}(\xi) = \hat{f}(\xi)$$

$$\Rightarrow \hat{y}(\xi) = \frac{\hat{f}(\xi)}{\sqrt{2\pi} \widehat{|x|^{-k}}(\xi)}$$

$$\Rightarrow y(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} \frac{\hat{f}(\xi)}{\sqrt{2\pi} \widehat{|x|^{-k}}(\xi)} e^{i\xi x} d\xi$$

$$\widehat{|x|^{-k}}(\xi) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} |x|^{-k} e^{-i\xi x} dx \quad \checkmark$$

$$f * g(x) = \int_{-\infty}^{\infty} \hat{f}(\xi) \cdot \hat{g}(\xi) e^{i\xi x} d\xi$$

$$= \frac{1}{\sqrt{2\pi}} \int_0^{\infty} x^{-k} e^{-i\xi x} dx + \frac{1}{\sqrt{2\pi}} \int_{-\infty}^0 (-x)^{-k} e^{-i\xi x} dx$$

$$\underline{(-x)^{-k} = -e^{-k} x^{-k}}$$

$\int_{-\infty}^{\infty} f(x) \cos \xi x dx$

So if you now use again if you try to use $X = -T$ if you put, okay, if you evaluate $X = -T$ DX is minus minus plus and this is going to be infinity to 0, and you have $-X$ power $-1/2$ 1 by so you get $-T$ power $-1/2$ that comes again as $-I$ times root T , T power $-1/2$, so if you do that $-I$ comes again outside that is going to be I square that is plus okay and this is going to be, so T power $-1/2$ and you have E power $+I \xi T$ and this is DT , okay so again when you replace -0 to infinity this is going to be minus, so this is how if you replace a dummy variable T with X and this is also with X , this is also with X , this is exactly what you have, this Fourier transform this is this now if you use these two integrals we have just now evaluated and put it here what we see is you can get what exactly the value of this Fourier transform. Fourier transform of X power mod X power $-1/2$ will be, what you will see is it's going to be 1 by, see if you eventually if you calculate put in C , you will see that it's going to be $1/xi$, or x power $-1/2$ as your Fourier transform, we can just substitute and see that this is what you get.

So anyway, so when you do this if you actually see this substitute and see what you end up is you will see that is going to be mod x power $-1/2$, we'll just calculate take it as an exercise and you will see that this if you substitute these two integrals you evaluate it like I have done in those two integrals you try to calculate like here how to calculate this integral evaluated this integral, now we evaluated $+I \xi$ you see that what exactly you get and you substitute into these two integrals here and you end up getting this, so Fourier transform of X power $-1/2$ x will be

Transform Techniques for Engineers 2 - Windows Journal

Sol: By Applying Fourier transform, we get

$$\widehat{|x|^{-1/2} * y(x)}(\xi) = \sqrt{2\pi} \widehat{|x|^{-1/2}}(\xi) \cdot \hat{y}(\xi) = \hat{f}(\xi)$$

$$\Rightarrow \hat{y}(\xi) = \frac{\hat{f}(\xi)}{\sqrt{2\pi} |x|^{-1/2}(\xi)}$$

$$\Rightarrow y(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} \frac{\hat{f}(\xi)}{\sqrt{2\pi} |\xi|^{-1/2}} e^{i\xi x} d\xi$$

$$\widehat{|x|^{-1/2}}(\xi) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} |x|^{-1/2} e^{-i\xi x} dx \checkmark$$

$$f * g(x) = \int_{-\infty}^{\infty} \hat{f}(\xi) \cdot \hat{g}(\xi) e^{i\xi x} d\xi$$

$$= \frac{1}{\sqrt{2\pi}} \int_0^{\infty} x^{-1/2} e^{-i\xi x} dx - \frac{1}{\sqrt{2\pi}} \int_0^{\infty} x^{-1/2} e^{i\xi x} dx$$

$$= |x|^{-1/2}$$

mod xi power -1/2, so what I do is this one you simply this is, so instead of writing here I write here so that you have mod xi power 1/2 on side you take it up, okay, so here I will try to invert here so this is going to be, this is actually equal to 1/root 2 pi times, what I do is -I square I use -I xi Fcap(xi) multiplied with I already have xi here so I need to have xi, okay, here you have a mod xi, if you multiply mod xi here I have already, I need to have mod xi power 1/2 so you have mod xi power -1/2 times, -I to compensate with this you need to multiply I so that this is exactly same as that, so this is equal to 1/root 2 pi -I mod xi times Fcap of, okay, so here I split this mod xi as xi times signature function of xi okay.

Transform Techniques for Engineers 2 - Windows Journal

Sol: By Applying Fourier transform, we get

$$\widehat{|x|^{-1/2} * y(x)}(\xi) = \sqrt{2\pi} \widehat{|x|^{-1/2}}(\xi) \cdot \hat{y}(\xi) = \hat{f}(\xi)$$

$$\Rightarrow \hat{y}(\xi) = \frac{\hat{f}(\xi) |\xi|^{1/2}}{\sqrt{2\pi}} = \frac{1}{\sqrt{2\pi}} -i\xi \hat{f}(\xi) \cdot |\xi|^{-1/2}$$

$$= \frac{1}{\sqrt{2\pi}} (-i\xi \hat{f})(\xi \text{sgn}(\xi) |\xi|^{-1/2})$$

$$\Rightarrow |\xi| = \xi \text{sgn}(\xi) = \begin{cases} \xi & \xi > 0 \\ -\xi & \xi < 0 \end{cases}$$

$$\widehat{|x|^{-1/2}}(\xi) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} |x|^{-1/2} e^{-i\xi x} dx \checkmark$$

$$f * g(x) = \int_{-\infty}^{\infty} \hat{f}(\xi) \cdot \hat{g}(\xi) e^{i\xi x} d\xi$$

$$= \frac{1}{\sqrt{2\pi}} \int_0^{\infty} x^{-1/2} e^{-i\xi x} dx - \frac{1}{\sqrt{2\pi}} \int_0^{\infty} x^{-1/2} e^{i\xi x} dx$$

$$= |x|^{-1/2}$$

What is signature function of xi? When xi is positive this is going to be 1 so you have xi, and xi is negative this is going to be -1 so you have -xi, this is exactly mod xi function, so mod xi is so you also multiply with the SGN signature of xi that I include here, SGN(xi) I times of this mod xi times -1/2, so these are the two functions I use, so if I now use this, if I now use this one so I will remove this, so how do I integrate, so if I this is a product of two Fourier transform of 2 such functions this I know, this is the Fourier transform of what you get root 2 pi times, what is the Fourier transform of, Fourier transform of F cap(x) let us say, what is this one? This is actually -xi F cap(xi), so in the place of this, in the place of this I put this one so Fourier transform of 1/root 2 pi, and this I can write F dash(x) Fourier transform, okay, which is a function of xi times.

Again one more what about this? Isine xi, so if you use, make use of this similar thing or the make use of this integral that I have evaluated so if you use, I give as a, give it as an exercise I'll directly write here and this I sign, I signature of xi times mod xi power -1/2 is actually equal to Fourier transform of mod X power -1/2 SGN(x), so you try to calculate this so if you do this, if

Transform Techniques for Engineers 2 - Windows Journal

Soln: By Applying Fourier transform, we get

$$\widehat{|x|^{-1/2} * y(x)}(\xi) = \sqrt{2\pi} \widehat{|x|^{-1/2}}(\xi) \cdot \hat{y}(\xi) = \hat{f}(\xi)$$

$$\Rightarrow \hat{y}(\xi) = \frac{\hat{f}(\xi) |\xi|^{1/2}}{\sqrt{2\pi}} = \frac{1}{\sqrt{2\pi}} (-i \text{sgn}(\xi)) \widehat{|x|^{-1/2}}(\xi)$$

$$\Rightarrow \widehat{|x|^{-1/2}}(\xi) = \frac{1}{\sqrt{2\pi}} \widehat{\text{sgn}(x)}(\xi)$$

$$\widehat{|x|^{-1/2}}(\xi) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} |x|^{-1/2} e^{-i\xi x} dx$$

$$f * g(x) = \int_{-\infty}^{\infty} \hat{f}(\xi) \hat{g}(\xi) e^{i\xi x} d\xi$$

$$= \frac{1}{\sqrt{2\pi}} \int_0^{\infty} x^{-1/2} e^{-i\xi x} dx - \frac{1}{\sqrt{2\pi}} \int_0^{\infty} x^{-1/2} e^{i\xi x} dx$$

$$= \frac{1}{\sqrt{2\pi}} \int_0^{\infty} x^{-1/2} dx$$

Integral $\int_{-\infty}^{\infty} \frac{F(y(x))(\xi)}{C} = \sqrt{\frac{2\pi}{C}} \int_0^{\infty} y(x) \frac{\sin \xi x}{\cos \xi x} dx$

$$f(x, z) = \frac{\cos \xi x}{\sin \xi x}$$

you try to calculate this Fourier transform you will end up getting this one by making use of the integral that just evaluated, so if I write like this so this will be X power -1/2 SGN(x) signature only F(x) for which you have Fourier transform of xi, so that is exactly what I wrote for both of this, okay.

Transform Techniques for Engineers 2 - Windows Journal

Sol: By Applying Fourier transform, we get

$$\widehat{|x|^{-1/2} * y(x)}(\xi) = \sqrt{2\pi} \widehat{|x|^{-1/2}}(\xi) \cdot \widehat{y}(\xi) = \widehat{f}(\xi)$$

$$\Rightarrow \widehat{y}(\xi) = \frac{\widehat{f}(\xi) |\xi|^{1/2}}{\sqrt{2\pi}} = \frac{1}{\sqrt{2\pi}} (-i \xi \widehat{f}(\xi)) \cdot |\xi|^{-1/2}$$

$$= \frac{1}{\sqrt{2\pi}} (-i \xi \widehat{f}(\xi)) (i \operatorname{sgn}(\xi) |\xi|^{-1/2}) = \frac{1}{\sqrt{2\pi}} \int_0^{\infty} x^{-1/2} e^{-i\xi x} dx - \frac{1}{\sqrt{2\pi}} \int_0^{\infty} x^{-1/2} e^{i\xi x} dx$$

$$= \frac{1}{\sqrt{2\pi}} \widehat{f(x)}(\xi) \cdot \widehat{x^{-1/2} \operatorname{sgn}(x)}(\xi) = |\xi|^{-1/2}$$

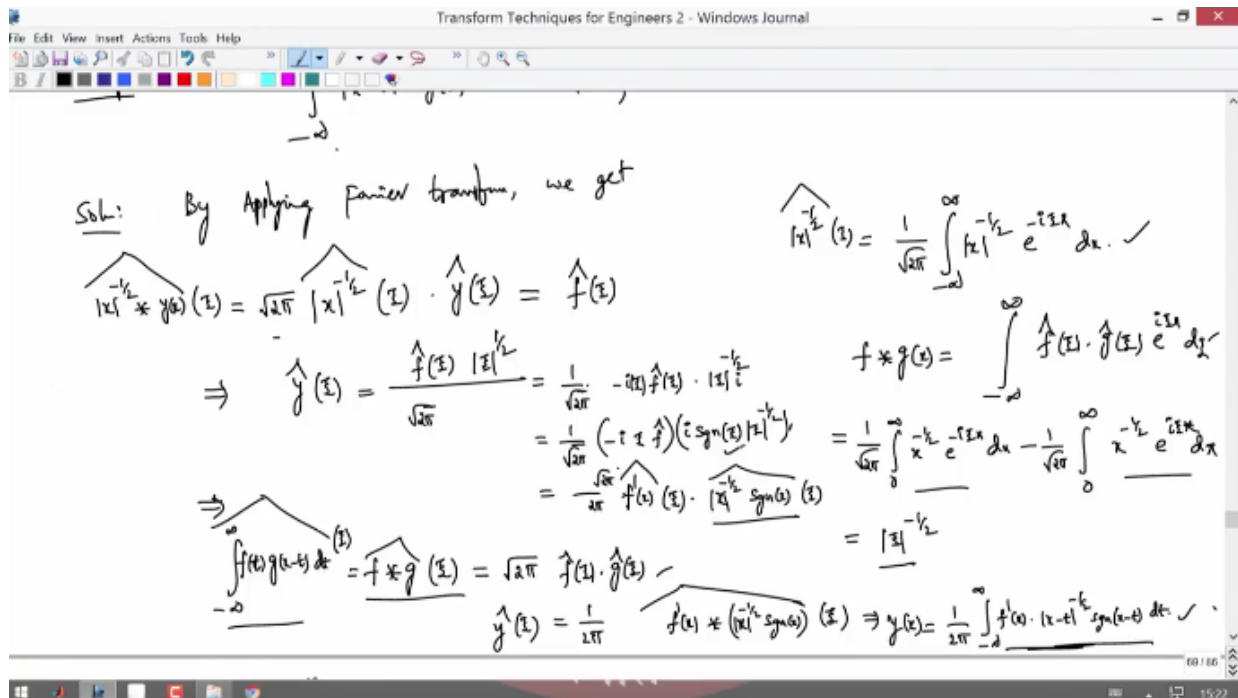

$$\int_{-\infty}^{\infty} f(x) g(x-t) dx = f * g(\xi) = \sqrt{2\pi} \widehat{f}(\xi) \cdot \widehat{g}(\xi)$$

$$\widehat{f}(\xi) = \frac{1}{\sqrt{2\pi}} \widehat{f(x) * (x^{-1/2} \operatorname{sgn}(x))}(\xi)$$

Integral eq. for $F_c(y(x))(\xi) = \sqrt{\frac{2}{\pi}} \int_0^{\infty} y(x) \frac{\sin \xi x}{\cos \xi x} dx$

$$f_c(\xi, \eta) = \frac{\cos \xi \eta}{\sin \xi \eta}$$

Now you take the inverse transform then what you get is $F(x)$ which is equal to $1/2 \pi$ times this integral minus infinity to infinity $F'(x)$ times F is given function in this integral equation, right hand side F' , so it's assume that F is differentiable so you have $F'(x)$ convolving with $\operatorname{mod} X$ power, so it is actually $\operatorname{mod} X$, okay, so where is this one? I think I have written, so this should be, this is actually, this is actually Fourier transform of $\operatorname{mod} X$ power minus of signature of X , there's a mistake, so you write like and you have $X^{-1/2} \operatorname{sgn}(x-t)$ DT that is exactly your solution, sorry this is here Fourier transform, this is your Y cap, so this is your $Y(x)$, $Y(x)$ is this this is your solution of the integral equation, so the rudiment of this, you know the important quantity that you have to evaluate is this integral, so this integral is we just made use of this gamma function and we could evaluate and put $N = 1/2$ you see that this is the quantity for minus, $+ i \xi X$ you have a similar thing, so similar thing so you make use of these two, these integrals and you can evaluate this, you can evaluate this Fourier transform of this by writing separately, in the same way you can see that Fourier transform of this is same as Fourier transform of, same as this one, okay, Fourier transform of this is same as this second term.

So this things you take it in exercise and this is how you solve, you evaluate that integral this is a little tough but you try to understand and do the calculations you will see that this is going to be this one, this is your solution of the integral equation.

So I'll leave it here we'll try to do some other problem which is a little easier to do, so let me do for the sake of solving some simpler problem, let's solve one more example, solve some $U(x)$ times or let me use $Y(x) - 1/2$ minus infinity to infinity $Y(t)$ this integral equation if you solve, you want to solve this $DT = F(x)$, F is anything and you have X is between minus infinity to infinity, so again the procedure is same you apply the domain is full domain, you can apply the Fourier transforms so that you have first term is $Y \text{ cap}(\xi)$ and this one, this is actually minus Fourier transform of $Y \text{ cap}$, so this is a convolution product of E power $-2T$ convolving with Y , okay this is exactly your function, so this is a convolution function, convolution of these two functions so when you take the Fourier transform for this with $1/2$, okay, $1/2$ times if you take the Fourier transform of this, this is actually this on which you take the Fourier transform what you see is it's going to be minus, this is going to be 4 so A square, this -2 is A , so A square divided by, so what you are evaluating is this is going to be 1 over, rather 4 divided by $\xi^2 + 4$, $\xi^2 + 2$ square, okay, so what exactly is a Fourier transform of 2 power $2X$ E power $-I \xi X$ integral minus infinity to infinity DX , this is going to be, and now this is actually mod T , this is mod T , so E power -2 mod T , so if you do this so you have to calculate for this, you have to calculate this one so you write 0 to infinity E power $-2X$, E power $-I \xi X$ DX that is $1 +$ minus infinity to 0 E power $-2X$, when X is negative this is going to be $+2XE$ power $-I \xi X$ DX , so once you substitute this with $-X$ with X is going to be 0 to infinity and you have minus and this is going to be plus and this is exactly, these are the two things you evaluate and try to substitute you see that, you will see that this is what is the quantity, so 2 goes so you have 2 so you will see that this is what you get, so this is into your $Y \text{ cap}(\xi)$, Fourier transform of this will be this, and Fourier transform (y) is this, okay, so this is equal to $F \text{ cap}(\xi)$.

So this will give me $Y \text{ cap}(\xi)$ as $F \text{ cap}(\xi)$ times $\xi^2 + 4$ divided by, $\xi^2 + 4 - 2$ that is $\xi^2 + 2$, so this is same as $F \text{ cap}(\xi)$ you write $\xi^2 + 4$ as $\xi^2 + 2 + 2$, so then one cancel the first term and you have $F \text{ cap}(\xi) + 2$ divided by $\xi^2 + 2$ and you have F

cap(xi), now you take the inverse transform for this both sides, you'll get Y(x) as if you take Fourier inverse transform that is F(x) and this one and you have again, so this is like you can write like 1/root 2 divided by, okay, so you write like xi square + root 2 square divided by 2, 2 root 2, if you actually see you will see that it's going to be 2 root 2, so I'm not evaluating this, so you'll try to evaluate Fourier transform of E power -root 2 mod X, Fourier transform of this is actually equal to this one, okay, if you directly use the same way if you try to calculate it, split into two parts for mod I mod X - I have 0 to infinity it is X, - infinity to 0 this is -X if you do and calculate you will end up seeing that this is the case, so if I 2 divided by this is actually

The screenshot shows a Windows Journal window with the following handwritten content:

Example: Solve $y(x) = \frac{1}{2} \int_{-x}^{\infty} y(t) e^{-\sqrt{2}|x-t|} dt = f(x), -\infty < x < \infty.$

Fourier transform of both sides:

$$\hat{y}(\xi) = \frac{2}{\xi^2 + 4} \hat{y}(\xi) = \hat{f}(\xi)$$

$$\Rightarrow \hat{y}(\xi) = \hat{f}(\xi) \cdot \frac{\xi^2 + 4}{\xi^2 + 2} = \hat{f}(\xi) + \frac{2}{\xi^2 + 2} \hat{f}(\xi)$$

Fourier transform of the kernel:

$$\int_{-\infty}^{\infty} e^{-\sqrt{2}|x|} e^{-i\xi x} dx = \int_0^{\infty} e^{-\sqrt{2}x} e^{-i\xi x} dx + \int_0^{\infty} e^{-\sqrt{2}x} e^{i\xi x} dx$$

$\Rightarrow y(x) = f(x) + \frac{2\sqrt{2}}{\xi^2 + (\sqrt{2})^2} = e^{-\sqrt{2}|x|} f(x)$

1/√2, 1/√2, 1/√2 times Fourier transform of this one, what is that? This is actually Fourier transform of, we have not done this so anyway so you can see you know I'm directly writing, so this is a product of two parts, two parts is a product you write this as Fourier transform of, so if you write this is a convolution of, I am writing directly, convolution of E power -root 2 mod X convolution with F(x) this function convolution function of X for which whose Fourier transform is this one, so that you can take it as an exercise with 1/√2 comes out, so this whole thing if you do that take the Fourier transform what you end up is this product of these two, okay.

Transform Techniques for Engineers 2 - Windows Journal

Example: Solve $y(x) - \frac{1}{2} \int_{-x}^0 y(t) e^{-2|x-t|} dt = f(x), -\infty < x < \infty.$

$\hat{y}(\xi) - \frac{2}{\xi^2 + 4} \hat{y}(\xi) = \hat{f}(\xi)$

$\Rightarrow \hat{y}(\xi) = \hat{f}(\xi) \cdot \frac{\xi^2 + 4}{\xi^2 + 2} = \hat{f}(\xi) + \frac{2}{\xi + 2} \hat{f}(\xi).$

$\Rightarrow \boxed{y(x) = f(x) + \frac{1}{\sqrt{2}} \left(e^{-\sqrt{2}|x|} * f(x) \right)}$ ✓

73/86 15:29

So this take it as an exercise this is how you get a solution of an integral equation just by applying direct Fourier transform for each of the terms and then you get this unknown term Fourier transform is given with known terms, you take the inverse transform that is what exactly the solution it'll be, okay, so this is how we can apply Fourier transform to find the solutions of linear, simple linear integral equations.

We'll also do some more similar problems on using, you can also work out some Fourier transforms directly, direct Fourier sine transform Fourier cosine transform or Fourier transforms, so I will give as an assignment certain problems so that you just need to find its inverse, to find the solution of this transforms you just identify the linear equation as Fourier sine transform with right hand side is given, so if you try to invert it that is the solution of this integral equation which is Fourier sine transform or cosine transform.

So just for the sake of repeating and let me, which I explained in the last video this is exactly, see if this is your sine transform of Fourier cosine transform if it with sine this is going to be F(S), okay, either C or S okay, Cor S cosine or sine, or sine for this, cosine is for the below, so

Fourier sine or cosine is this, if this function is given you want to, if unknown is $Y(x)$ inverse transform will give you Φ_c or Φ_s okay, this is what you get Fourier sine, Φ_s corresponds to sine, Φ_c corresponds to cosine, so anyone of them, Φ_c if you put it so you put it in the bracket, so that if you choose Φ_c you have to choose cosine. So directly this is just we know that it's inverse transform of this, this one, given this one you can calculate this, okay, you can just by inverse transform.

Similarly you can use the full Fourier transform and its inverse transform is, will give you the solution of this integral equation, if this right-hand side means this is given, F_c is given and this is an integral equation, simple linear integral equation of course first kind because this unknown is not outside, okay, so this is exactly the linear equation which you can solve just by inversion, so these things I give as the direct problems in assignment you can do later.

So what are the other applications you can do? You can also evaluate certain integrals, certain integrals you can evaluate if I'll just do one example in this video, I realize that this is not the Fourier transform of this derivative, derivative is actually with our definition this is actually $i \xi f(x)$, so that to account for minus you have to write it here, so we put it here, this minus you put it here so that you can calculate that minus you can always take it out and you can write this as Y_c $-1/\pi$ and this one, this is exactly what you have, so this is small correction here so earlier I put $-i \xi f(x)$ whose Fourier, that is Fourier transform of F_c , now it is a Fourier transform of F_c is $i \xi$ times F_c , earlier I write $-i \xi$ so that is the only thing, so you will see similar things such thing okay so you have a minus something like with minus, and you have this signature thing so you just have to verify whether this is Fourier transform of this, is actually this or not, okay, without this negative sign, so negative sign you can put it here so whether this is the Fourier transform of this I have to see, okay, so that's only then start, okay, so that's the only small amendment we can make, so we can also evaluate, we use a convolution product, we can use some another application is evolution can evaluate certain integrals, some integrals we can evaluate just by using the property of the Fourier transform that is Fourier transform of this convolution product, this is actually equal to which is a Fourier transform of convolution product is a function of X which is finally after taking the Fourier transform this function of ξ

is actually equal to $\sqrt{2\pi}$ times $F(\omega)$ times $G(\omega)$, okay, so we can evaluate by making use of this, and this one and we also used Parseval's inequality, okay, so what we have is, so we just look back what is the property that we have used in the Parseval's identity you have this one, Fourier inversion will give me this one, so we'll go so what you end up is this one, so Parseval's identity is this, $F(\omega)$ so without this, so you have, we try to use this one, we try to use this.

The image shows a software window titled "Transform Techniques for Engineers 2 - Windows Journal" containing handwritten mathematical derivations. The derivations are as follows:

$$\int_{-\infty}^{\infty} f(x-y)g(y)dy = f * g(x) = \int_{-\infty}^{\infty} \hat{f}(\xi) \cdot \hat{g}(\xi) e^{i\xi x} d\xi$$

put $x=0$,

$$\int_{-\infty}^{\infty} f(-y)g(y)dy = \int_{-\infty}^{\infty} \hat{f}(\xi) \hat{g}(\xi) d\xi \quad \checkmark$$

$$\int_{-\infty}^{\infty} f(t)g(-t)dt = \int_{-\infty}^{\infty} \hat{f}(\xi) \hat{g}(\xi) d\xi \quad \checkmark$$

Let $g(-t) = \overline{f(t)}$, then $\hat{g}(\xi) = \widehat{g(-t)}(\xi) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} g(t) e^{-i\xi t} dt = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} \overline{f(t)} e^{-i\xi t} dt$

$$= \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} f(t) e^{-i\xi(-t)} dt$$

$-t = \tau$

$$\int_{-\infty}^{\infty} |f(t)|^2 dt = \int_{-\infty}^{\infty} \hat{f}(\xi) \overline{\hat{f}(\xi)} d\xi$$

So we will basically use this one, this equality this is from Parseval's identity that property 10 if we use, if you want to evaluate, if you know that if your integral, integral is involving some product of 2 products suppose you have $D(\omega)$, and each of this you know what is its Fourier inverse transform, so that you can put it there and you can evaluate this, suppose after putting this, after getting this inversion if you can evaluate this integral this is you can easily evaluate this integral, and so that finally so this integral will be known, okay, so with this idea we'll try to evaluate.

$\int_{-\infty}^{\infty} f(x)g(x) dx = \int_{-\infty}^{\infty} \hat{f}(z) \hat{g}(z) dz$

put $x=0$, $\int_{-\infty}^{\infty} f(-y) g(y) dy = \int_{-\infty}^{\infty} \hat{f}(z) \hat{g}(z) dz$

$\int_{-\infty}^{\infty} f(t) g(-t) dt = \int_{-\infty}^{\infty} \hat{f}(z) \hat{g}(z) dz$ ✓

Let $g(-t) = \overline{f(t)}$, then $\hat{g}(z) = \widehat{g(-t)}(z) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} g(t) e^{-izt} dt = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} \overline{f(t)} e^{-izt} dt$

$\int_{-\infty}^{\infty} |f(t)|^2 dt = \int_{-\infty}^{\infty} \hat{f}(z) \overline{\hat{f}(z)} dz$ ✓

$\int_{-\infty}^{\infty} |f(t)|^2 dt = \int_{-\infty}^{\infty} |\hat{f}(z)|^2 dz$ ✓

$\hat{g}(z) = \overline{\hat{f}(z)}$ ✓

$\int_{-\infty}^{\infty} f(t) e^{-izt} dt = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} f(t) e^{-izt} dt$

$-t = x$

$= \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} f(x) e^{-izx} dx$

$\hat{g}(z) = \overline{\hat{f}(z)}$

40 / 60

So we'll use $F(-y) G(y)$ minus infinity to infinity, so let me use this one, so $F(-y) G(y) DY, F(-y) G(y) DY$ is same as minus infinity to infinity, $F \cap (xi) \rightarrow G \cap (xi) D xi$, so from this either this or this both are same so from this you got this one, okay as a property, this is one property and making use of this we got this property, this is a part of this Parseval's identity so we make use of this to evaluate some integrals, for example one example is can do evaluate integral minus infinity to infinity I equal to, we want to find the value of I, I is from DX divide

Transform Techniques for Engineers 2 - Windows Journal

File Edit View Insert Actions Tools Help

Evaluate some integrals:

$\widehat{f * g}(z) = \sqrt{2\pi} \hat{f}(z) \hat{g}(z)$ ✓

↓

$\int_{-\infty}^{\infty} f(-y) g(y) dy = \int_{-\infty}^{\infty} \hat{f}(z) \hat{g}(z) dz$ ✓

Example: Evaluate $I = \int_{-\infty}^{\infty} \frac{dx}{(x^2 + a^2)(x^2 + b^2)}$

73 / 60

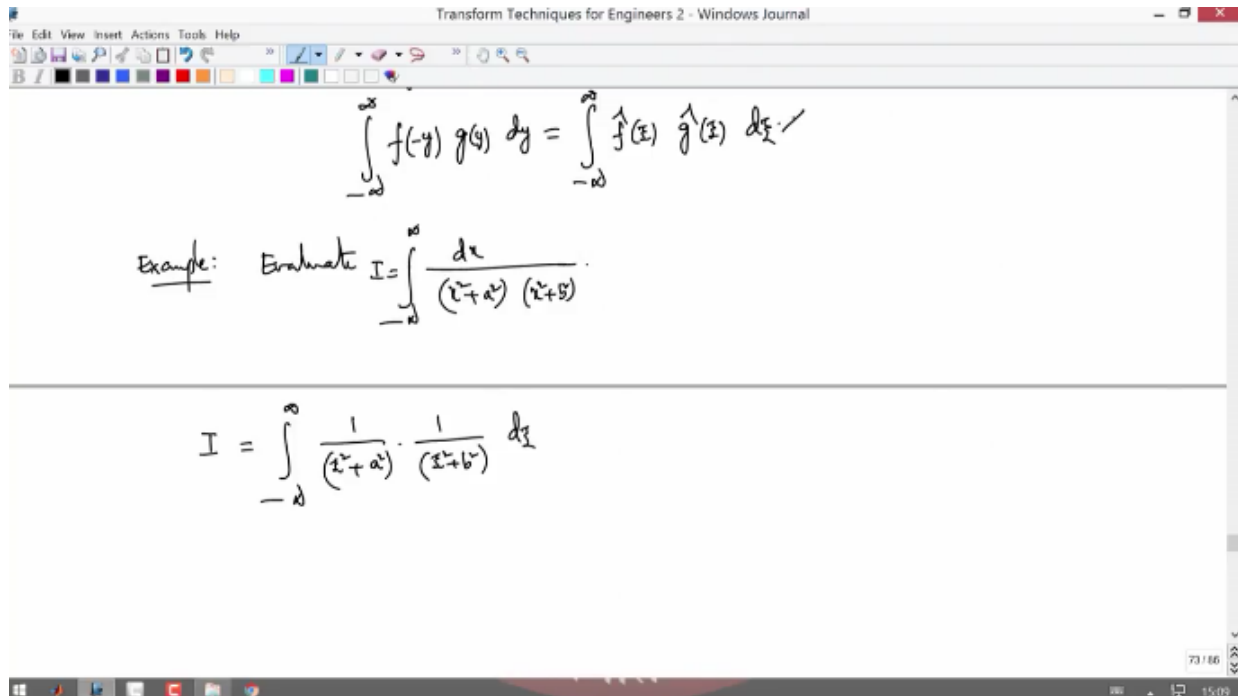

by $X^2 + A^2$ times $X^2 + B^2$, okay, so this is equal to you can rewrite like $D/x^2 + A^2 + B^2$, so as the 2 products you can write like 2 product types, one of this $D/x^2 + A^2$, I just change the dummy variable and then this we know that this

is inverse transform of this one, so this is by the earlier this property we can rewrite this is equal to minus infinity to infinity, this is suppose your F, this is your G cap, this is your F cap and this is your G cap, then what you have is F cap and you have this, this is going to be suppose this is your F and this is your G, okay, so if this is your F cap what you have to write is F here so if this is your F the inverse transform, so we F inverse of F/ xi square + A square times F inverse of which is a function of, for example here I have to write function of -Y times F inverse(1/xi square + B square) as a function of Y.

Example: Evaluate $I = \int_{-\infty}^{\infty} \frac{dx}{(x^2+a^2)(x^2+b^2)}$.

$$= \int_{-\infty}^{\infty} \frac{1}{f} \cdot \frac{1}{g} \cdot dx = \int_{-\infty}^{\infty} f^{-1}\left(\frac{1}{x^2+a^2}\right)(-y) \cdot f^{-1}\left(\frac{1}{x^2+b^2}\right)(y) dy.$$

See if this is a G cap where we are writing G(y) so we are using this one, so left hand side I'm writing here, so when you get this inverse transform of F and that as you get a function of Y finally replace Y by -Y and here you do this, so if you use this you can easily see that this is going to be, so you can you know you try to calculate this Fourier inversion of both, Fourier inversion of for this we already seen if you have seen earlier Fourier transform of E power -A mod X is actually Fourier transform of this if you calculate, you try to see that it's going to be one such integrals, so you will get 1/xi square + something into 1/xi square + X square, so if you have seen earlier I don't know whether I have done, I'll just let me see, so we have this integral I which is minus infinity to infinity, so you can split this as sum xi square + A square into 1/xi square + B square into D xi, so I just changed the dummy variable.

Now we make use of this inequality here, we make use of this equality so if you use this so you want to see identify this as right hand side so that implies what you have is the $F(\xi)$ you're looking for $1/\xi^2 + A^2$, what is its inversion? So inversion you're looking for, so you have $F(x)$ will be, so integral $1/\sqrt{2\pi}$ minus infinity to infinity $\int_{-\infty}^{\infty} \frac{dx}{x^2 + A^2}$, so this if you want to evaluate you can evaluate this and get your function $F(x)$ that is one way, that is if you want to do this you have to use contour integration technique that is you consider minus infinity to infinity, you use this contour integration and you have x^2 , so your function consider this function $F(z)$ is over this, within this domain, integral over this domain ω , so consider, so do ω this is the contour we have consider, and that is your ω , if this is your ω , so contour is ω so this is DZ . So what is your function, $F(z)$ is I consider E^{XZ} , X is fixed number, Z divided by $Z^2 + A^2$, so the singularities of this function if you know a little bit of complex analysis, complex variables you have, Z is $-iA$, okay, so those are that is what you get is $-A^2$, Z^2 is $-A^2$ and Z is $+iA$, so these are the roots, these are the singularities, one point will be somewhere here other will be down, so you have a singularity

$$I = \int_{-\infty}^{\infty} \frac{1}{(z+a)} \cdot \frac{1}{(z+b)} dz$$

$$\Rightarrow \hat{f}(z) = \frac{1}{z+a}$$

$$f(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} \frac{1}{z+a} e^{iz} dz$$

$$\int_{2\pi} f(z) dz =$$

$$f(z) = \frac{e^{iz}}{z+a}$$

$$z = \pm ia$$

76 / 80

inside there is a theorem that tells you that this is actually equal to $2\pi i$ times, this $2\pi i$ times some residues, residue of this $F(z)$, as Z goes to this IA , okay, at $Z = IA$, so the meaning of residue is this limit, basically if you don't know what is residue you have to write $(Z-IA)$ times $F(z)$, now you take the limit Z goes to IA , so that is actually is the residue, so $2\pi i$ times is that the whole thing, so this is equal to, the residue means just this limit and $2\pi i$ times that, so this is equal to that, so if you calculate this that you can easily calculate because we know what is the $F(z)$ and then you can calculate this, because you will see that is, this over which this you can actually prove by some theorem in the complex variables that over which this is 0 because this is exponential, function is you have oscillator function divided by some more than order of Z more than Z order, okay, so you can easily, one can prove that is actually on this it is 0, so you have this one is actually $2\pi i$ times this, that is one way of to find evaluate this

transform techniques for engineers - windows journal

File Edit View Insert Actions Tools Help

$$I = \int_{-\infty}^{\infty} \frac{1}{(x^2+a^2)} \cdot \frac{1}{(x^2+b^2)} dx$$

$$\Rightarrow \hat{f}(s) = \frac{1}{s^2+a^2}$$

$$f(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} \frac{1}{s^2+a^2} e^{isz} ds \quad \checkmark$$

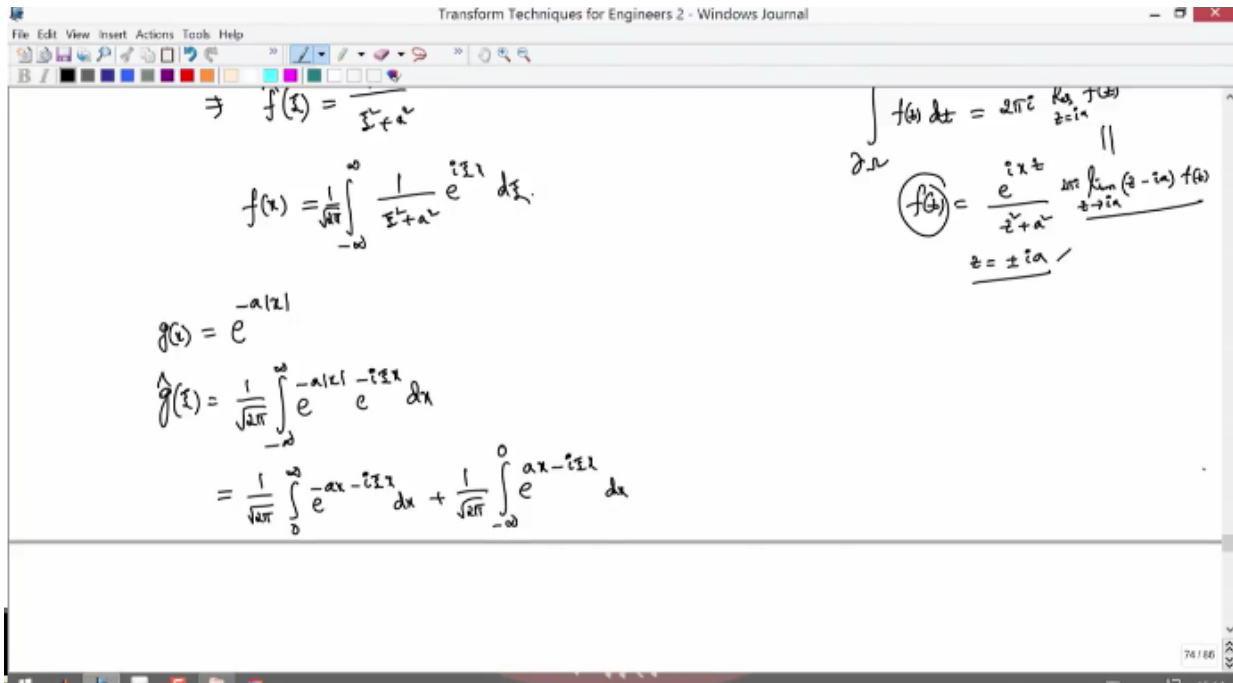

$$\int_{\gamma} f(z) dz = 2\pi i \sum_{z=i\alpha} \text{Res } f(z)$$

$$\hat{f}(z) = \frac{e^{izx}}{z^2+a^2} \quad \lim_{z \rightarrow ia} (z-ia) f(z)$$

$$z = \pm ia \quad \checkmark$$

integral, so instead of doing this way if you know complex variables you calculate this and you will end up finally what is this function, so I do it in a different way, I'll try to see that $1/x^2 + A^2$, okay, so I consider my I , a priori I know as though I know this function $F(x)$, if you calculate this complex variable technique you can get it.

Let me calculate $E^{-Ax} \text{ mod } X$, if this is my function $F(x)$ okay, let us say some $G(x)$ is this function, so what happens to its Fourier transform, so $G \text{ cap } (xi)$ is actually equal to $1/\sqrt{2\pi}$ and integral minus infinity to infinity, $E^{-Ax} \text{ mod } X$, $E^{-Ixi} X \text{ DX}$, this is what is Fourier transform, so this you split it, split this integrals from 0 to infinity and you get this will be, if it's X is positive this is going to be E^{-AX} and then you have $-Ixi X$ that is one DX and if it is other part will be $1/\sqrt{2\pi}$ - infinity to 0, in this case it's going to be AX when X is negative, $\text{mod } X$ is $-X$ so minus minus plus so you have AX and here you have $Ixi X \text{ DX}$.

Now if you root, if you substitute X/-X so you get a minus for DX and this is going to be infinity to 0 and here you have a-AX and you have a +AX, so this is what you get and because - infinity to 0 so you can make it plusher and then write 0 to infinity, so these are the two integrals you get, so one is this 1/root 2 pi so this you can easily evaluate, so this is E power A+ I xi into X, so 1 over A + I xi times E power -A + I xi X for which you apply 0 to infinity, this is one first integral, a second integral will be 1/root 2 pi E power -A - I xi times X divided by A- I xi, this is also from 0 to infinity, this is equal to 1/root 2 pi and this is going to be, and of course you have a minus sign, minus sign you have in a differentiate you can get the minus sign, so this minus minus plus, this is minus of this quantity, so let me put this minus here, and so you see that this is going to be 1/root 2 pi, 1/A+ I xi because at infinity this is A is positive, so A is positive, let's choose this way so you have E power -AX, it's going to be at infinity it's 0, so this one minus, minus minus plus again so here also you get 1/root 2 pi 1 over A - I xi, so what you see is 1/root 2 pi, now you have A square - I square that is + xi square times, and what you get is this A-I xi + A + I xi that is 2A.

Transform Techniques for Engineers 2 - Windows Journal

$$g(x) = e^{-a|x|}, \quad a > 0$$

$$\hat{g}(\xi) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} e^{-a|x|} e^{-i\xi x} dx$$

$$= \frac{1}{\sqrt{2\pi}} \int_0^{\infty} e^{-ax - i\xi x} dx + \frac{1}{\sqrt{2\pi}} \int_0^{\infty} e^{-ax + i\xi x} dx$$

$$= \frac{1}{\sqrt{2\pi}} \left[\frac{1}{(a+i\xi)} e^{-(a+i\xi)x} \right]_0^{\infty} - \frac{1}{\sqrt{2\pi}} \left[\frac{1}{(a-i\xi)} e^{-(a-i\xi)x} \right]_0^{\infty}$$

$$= \frac{1}{\sqrt{2\pi}} \left[\frac{1}{a+i\xi} + \frac{1}{a-i\xi} \right] = \frac{1}{\sqrt{2\pi}} \frac{2a}{a^2 + \xi^2}$$

$$\Rightarrow \hat{g}(\xi) = \frac{1}{\sqrt{2\pi}} \frac{2a}{a^2 + \xi^2}$$

So this implies, so $\hat{G}(\xi)$ is actually equal to $1/\sqrt{2\pi} \cdot 2A/A^2 + \xi^2$, so if your G is, if I multiply with the root, if I consider this with $1/2A$, so let me choose with $1/2A$ for G I will have $1/2A$ here, and again I'll have $1/2A \cdot 1/2A$ because that my function G is that, so $2A \cdot 2A$ comes down you have $2A$, and finally you have $2A$ comes as a factor, and you have $2A$ so that gets cancelled, so we end up getting simply this, this is simply $1/\sqrt{2\pi} \cdot 1/A^2 + \xi^2$, okay, so if you don't want that root 2π also so you can also multiply here root 2π , so you can easily see Fourier transform of root 2π $E^{-A|x|}$ divided by $2A$, so let's divided by $2A$ for which if you take the Fourier transform that is actually equal to $1/A^2 + \xi^2$, so this is exactly you're going to write here, here in this I , this integral I can write this as, so this I will be now equal to integral minus infinity to infinity, so you have root $2\pi/2A$ times $E^{-A|x|}$ for which you have Fourier transform which is a function of ξ , okay, this is one function into other function this instead of A you have B , so you write like that Fourier transform of root $2\pi/2A E^{-B|x|}$ here, so $-B|x|$ which is a function of ξ , you have D ξ , so this is exactly what your integral is.

Fourier transform techniques for engineers - windows journal

le Edit View Insert Actions Tools Help

$$\int_{-\infty}^{\infty} f(y) g(y) dy = \int_{-\infty}^{\infty} \hat{f}(x) \hat{g}(x) dx$$

Example: Evaluate $I = \int_{-\infty}^{\infty} \frac{dx}{(x^2+a^2)(x^2+b^2)}$

$$I = \int_{-\infty}^{\infty} \frac{1}{(x^2+a^2)} \cdot \frac{1}{(x^2+b^2)} dx$$

$$\Rightarrow \hat{f}(z) = \frac{1}{z^2+a^2}$$

$$f(x) = \frac{1}{2\pi} \int_{-\infty}^{\infty} \frac{1}{z^2+a^2} e^{izx} dz$$

$$\int_{\gamma} f(z) dz = 2\pi i \sum_{\text{poles}} \text{Res} f(z)$$

$$\hat{f}(x) = \frac{1}{2\pi} \int_{-\infty}^{\infty} \frac{e^{izx}}{z^2+a^2} dz$$

This is the integral you won't evaluate that is this, but from this, this is a Fourier transform of, you put it in this form Fourier transform of this so that function you can write it here this side so that is a same saying, if you make use of this relation is actually equal to minus infinity to infinity, root 2 pi/2A this function E power -A mod X times root 2 pi/2B times E power -B mod X DX, okay, so because here in this I have to put X/-X and as in the relation here, F(-y) so because it involves the modulus so it is same, modulus of -X is same as mod X so, you have this is the relation so though your actual identity, the integral value is actually this integral, so if you take it out it's going to be 2 pi divided by 4AB so that makes it, divided by 2, okay, 2 pi/4AB and then you have this integral minus infinity to infinity E power -A+B mod X DX.

Now you see this integrand is even function, so you can write this as 2 times integral 0 to infinity E power -A+B mod X DX, mod X is when you write X is in 0 to infinity, mod X is you can replace as X DX, so you should write like this, now this is same as X is positive mod X is

$$\begin{aligned}
 &= \int_{-\infty}^{\infty} \frac{\sqrt{2\pi}}{2a} e^{-a|x|} \cdot \frac{\sqrt{2\pi}}{2b} e^{-b|x|} dx \quad \checkmark \\
 &= \frac{\pi}{2ab} \int_{-\infty}^{\infty} e^{-(a+b)|x|} dx \\
 &= \frac{\pi}{2ab} \cdot 2 \int_0^{\infty} e^{-(a+b)x} dx \\
 &= \frac{\pi}{ab} \cdot \frac{1}{a+b}
 \end{aligned}$$

simply X, so this is actually equal to, this goes you finally end up pi/AB times and this will give me like 1/A+B, this is how we can evaluate certain integrals using this Parseval's identity, so we will see some other examples and other applications in the next video. Thank you very much.
