Geometric Brownian motion

We have already seen in earlier lectures that the Brownian motion and the operator that Laplacian operator associated with that. And we have also seen the Feynman-Kac formula etc and we recall few things already we have seen and few things, you know which are immediate, but we have not discussed but which gives the power of calculations, etc.

So, these are the things we are going to discuss today and also we are going to understand why do we need to study some other stochastic processes beyond Brownian motion.

(Refer Slide Time: 01:03)

Tutorial

Let $W := \{W_t\}_{t \geq 0}$ be a standard Brownian motion.

- 1 We have already seen that $P(\langle W \rangle_t(\omega) = t, \text{ for all } t \geq 0) = 1$ in week 3.
- 2 However, the definition of quadratic variation of square integrable continuous martingale which was introduced in week 2 does not immediately suggest a way to find the expression of quadratic variation.
- 3 Nevertheless, when we know the quadratic variation of the Brownian motion, we can apply Ito's formula to obtain the Doob Meyer decomposition.
- 4 Applying Ito's formula on $f(x) = x^2$

$$\begin{aligned}
 W_t^2 &= W_0^2 + \int_0^t 2W_s dW_s + (1/2) \int_0^t 2d\langle W \rangle_s \\
 &= W_0^2 + \int_0^t 2W_s dW_s + t.
 \end{aligned}$$

So, here assume that W is the standard Brownian motion as we do all the time. So, here W_t , t greater or equals to 0, we have already seen in week 3 that probability that quadratic variation of W_t is equal to t for all t positive, 0 or positive okay. So, the quadratic variation process is actually the identity function of time okay.

So, this thing already we have seen and there how did you compute that for computing that we have taken a sequence of partitions, and there, we have taken the increments. So, we have

added square or the increments and we use the theorem that quantity, the summation of square of increments converging probability to the quadratic variation function.

Okay so, that was the thing what we have used to compute this thing okay, however, the definition of quadratic variation of square integrable continuous martingale which was introduced in week 2. So, that was done using the Doob Meyer decomposition correct. If you have a square integrable continuous martingale M , then M square is the sub martingale and that M square has Doob Meyer decomposition.

And in the Doob Meyer decomposition the non-martingale part, the part which is increasing part, so that constitutes the natural version of that constitutes to the quadratic variation of the process. So, that thing does not give you any indication how to compute quadratic variation, correct. So, that thing does not immediately suggest, we have to find the expression of quadratic variation.

Nevertheless, when we know the quadratic variation, I mean from this point also we have already obtained it of the Brownian motion. We can apply Ito's lemma to obtain the Doob Meyer decomposition, okay. So, the Doob Meyer decomposition we can obtain how do we do? We just take f of x is equal to x square, okay this function, okay. And then we apply f of W_t apply Ito's formula f of W_t .

So f of W_t is W_t square, so f of W_t is equal to f of W_0 that is W_0 square plus first order derivative of f that is $2x$, so 2 times W_s okay evaluated at W_s and (ds) dW_s is running from 0 to t . Then Ito's formula also have second order term. So, plus half times 0 to t , second derivative of f , so what is second derivative? The $2x$ derivative, is this 2 , correct? 2 and then the quadratic variation would appear or Brownian motion appear, okay.

And this already we have computed that these can be taken as just t here because this whole integration okay in this path, this is t , I mean okay so, I can write down s here, so half and 2 would cancel each other, so integration 0 to 2 of ds is t okay, t and here we have $2 \int_0^t W_s ds$, okay. So, W_t square is now written as some constant, so W_0 is actually 0 because standard Brownian motion is 0 is nothing is here and here we have into stochastic integration of 2 times Brownian motion with this Brownian motion, okay.

So, this stochastic integration gives me a local martingale okay, and here this is the remaining term, okay. So this is also that the Doob Meyer decomposition of W_t^2 okay. So this is obtained using the Ito's formula, okay.

(Refer Slide Time: 05:18)

- Hence, if F is twice continuously differentiable with all derivatives bounded, then Ito's lemma implies

$$F(t, W_t) = F(0, X_0) + \int_0^t F_x(W_s) dW_s + \int_0^t (F_t(W_s) + \frac{1}{2} F_{xx}(W_s)) ds.$$

- Indeed the following product table works for finding quadratic variation of another process whose infinitesimal change is written

using Brownian motion.

	dt	dW_t
dt	0	0
dW_t	0	dt

Definition (Geometric Brownian Motion (GBM) with drift)

$$S_t = e^{\alpha t + \beta W_t}$$

where α and β are constants.

Tutorial

Let $W := \{W_t\}_{t \geq 0}$ be a standard Brownian motion.

- We have already seen that $P(\langle W \rangle_t(\omega) = t, \text{ for all } t \geq 0) = 1$ in week 3.
- However, the definition of quadratic variation of square integrable continuous martingale which was introduced in week 2 does not immediately suggest a way to find the expression of quadratic variation.
- Nevertheless, when we know the quadratic variation of the Brownian motion, we can apply Ito's formula to obtain the Doob Meyer decomposition.

- Applying Ito's formula on $f(x) = x^2$

$$\begin{aligned} W_t^2 &= W_0^2 + \int_0^t 2W_s dW_s + (1/2) \int_0^t 2d\langle W \rangle_s \\ &= W_0^2 + \int_0^t 2W_s dW_s + t. \end{aligned}$$

So, after talking about Brownian motion, now we also so this is just Ito's formula of function of x but function of x and t if we have, so this is a special case. If f is twice continuously differentiable with all derivatives bounded then Ito's lemma also implies this also recollection of Ito's lemma what we have already seen.

That f of t, W_t is equal to f of $0, X_0$. So, here it should be W_0 okay, so this is a typo, plus integration 0 to t first derivative of f with respect to first derivative of f okay, with respect to the second variable. So, that is why I am writing x that means the second variable. For first

variable I will write t always. So $f(x, W_s) = \int_0^t \dots$ plus then first the derivative with respect to the first variable appears and then here I mean there I should have just small s W_s .

This is missing here also small s W_s , the function of 2 variables correct. So, this s , s is missing here, ds and then second order term that would give me half times double derivative of f with respect to the second variable and then quadratic variation of W that is ds .

So, quadratic variation of Brownian motion is s , okay so that is the reason that these both we can club together okay, because club together can write this manner, okay. So these are the things which is more or less recollection but this is something we are going to use also for some interesting examples.

So, here we now address a question that how can we find out quadratic variation of some other processes? For Brownian motion we have obtained right, the definition of quadratic variation did not help much but we had to actually use the property of Brownian motion that normal random variables etc and then the fourth order moment of the normal random variable is 3 times of you know of the square of the variance etc.

All these things have used there. So, here indeed the following product table works for finding quadratic variation of another process whose increment changes or increment if you say increment is retained is in Brownian motion okay. So, for that, so if I have a process X , so dX_t is written in terms of Brownian motions, increments, etc. So, dX_t whole square I can then find out okay.

And then actually I would have you know product of terms which has increment infinitesimal increments and then one should know that what are the, I mean what are the terms and how to manipulate those terms okay, this is not very clear. However, this table really works that whenever one has those type of products, so dt into dt one can put 0 dt and dW_t one can put 0 and dW_t into dW_t one can put dt okay, so this product table really works for calculating quadratic variation of some other processes, okay.

So, here we first talk about some process which is other than Brownian motion, say S_t okay, we define S_t is equal to $e^{\alpha t + \beta W_t}$ okay, where α and β are some constants, okay. So, this has a name this is called geometric Brownian motion

with drift okay. Why geometric? Because there is no geometry after all I mean it is just that product because Brownian motion has additive increment etc here that is in the power of e.

So like here, I mean the product type of things do appear here. So, that is why we call it geometric Brownian motion. So, we are going to study this S_t , okay. So, we would like to write down this S_t , the infinitesimal increment of S_t in terms of infinitesimal increment of W_t okay, so that is the kind of thing we want to do.

So, one can actually directly apply Ito's formula over this, this is a function of Brownian motion correct. One can apply this Ito's formula correct and by applying Ito's formula one can get dS_t correct. Okay so, that one can get and one can get the formula, okay. So, that is one way to find out the change of dS_t etc and then dS_t square one can find out, okay. There is another way, okay.

(Refer Slide Time: 10:17)

① We can use Itô's formula to solve

$$dS_t = \mu S_t dt + \sigma S_t dW_t.$$

② Let us assume that the above equation has a continuous solution with probability 1.

③ Let $f(S_t) := \log(S_t)$ for $t < \tau(\omega)$, where $\tau := \min\{t > 0; S_t \leq 0\}$. Then using $d(S_t)^2 = (\mu S_t dt + \sigma S_t dW_t)^2 = \sigma^2 S_t^2 dt$,

④

$$\begin{aligned} d \log S_t &= df(S_t) = f'(S_t) dS_t + \frac{1}{2} f''(S_t) S_t^2 \sigma^2 dt \\ &= \frac{1}{S_t} (\sigma S_t dW + \mu S_t dt) - \frac{1}{2} \sigma^2 dt \\ &= \sigma dW_t + \left(\mu - \frac{\sigma^2}{2}\right) dt. \end{aligned}$$

⑤ $\log S_t = \log S_0 + \sigma W_t + \left(\mu - \frac{\sigma^2}{2}\right)t$
 $\Rightarrow S_t = S_0 \exp(\sigma W_t + \left(\mu - \frac{\sigma^2}{2}\right)t) \quad \forall t < \tau_{\omega}$

- Hence, if F is twice continuously differentiable with all derivatives bounded, then Ito's lemma implies

$$F(t, W_t) = F(0, X_0) + \int_0^t F_x(W_s) dW_s + \int_0^t (F_t(W_s) + \frac{1}{2} F_{xx}(W_s)) ds.$$

- Indeed the following product table works for finding quadratic variation of another process whose infinitesimal change is written using Brownian motion.

	dt	dW_t
dt	0	0
dW_t	0	dt

Definition (Geometric Brownian Motion (GBM) with drift)

$$S_t = e^{\alpha t + \beta W_t}$$

where α and β are constants.

So, basically I am writing down what one would get. So, in general, so not with this alpha this beta but some other constant mu and sigma considered this type of description of a stochastic process where increment of the process, stochastic process at time t, dS_t is equal to mu a constant times $S_t dt$ plus sigma $S_t dW_t$ okay.

How are you going to understand this? We can understand this as a integral equation, correct. Because say for example, the integration sign is there, 0 to t, etc but that is I have just omitted and then S_t 's are unknown which appears both sides okay. So one can understand that this description as an equation. Okay so, we are going to see that, okay how are we going to solve these equation and what are you going to do?

But before that, let me explain that if dS_t has this form, then the quadratic variation of S_t would be just you take dS_t whole square, then you get mu $S_t dt$ plus sigma $S_t dW_t$ whole square term and then you use that product rule that product table, and then you would see the dt square term would not appear dt and dW_t that cross terms would also not appear only this term would appear and then there will be sigma $S_t dW_t$ whole square term would survive that would give me sigma square $S_t^2 dt$, okay.

So, the quadratic variation of S_t would become integration of sigma square S_t^2 with respect to time t okay. So, that is the kind of thing however, we need to build the connection between this and this without building this connection, the whole discussion is baseless, correct? So, we are going to build that connection okay.

So, one connection as I told that okay, you use Ito's lemma on this and get it, so that you can do as an exercise another because there is nothing to do much it is just in direct application you would get it I mean one can see from here directly that okay, one would get this type of terms because the derivative of these would you get partial derivative, this x variable would get beta terms here and same e to the power $S t dW$ s okay.

And then for time here, you get alpha terms. From here you would get half of beta square okay. So, you are going to get here, so we are not bothering much in that direction but the reverse direction. So, as you know that I do not have that I just have this thing okay. Then how to come up with that okay that solution, we can call them this thing as a solution of this equation. Okay so, we proceed this way.

So for the time being because we do not have any way to actually assert that this has a solution for the time being, we assume that the above equation has a continuous solution with probability one, okay. We assume that it has and when we assume and then you obtain that form and then we can do the reverse thing. We can actually use Ito's formula to cross verify that okay this is indeed the solution, okay.

So, assume that it has a continuous solution, I mean, this kind of treatment what I am doing now, is very similar as you have done in your college in your graduation level. When given an ODE ordinary differential equation, you try to find out the solution. Try to find out the form of the solution, correct? Without bothering much whether the solution exists or not okay, you believe that it exists and then applied some formula to solve it.

And this is actually a correct occasion to clarify the importance of Ito's lemma, because when you try to solve ordinary differential equation, what you actually have done is that you try to integrate, okay you try to integrate. You tried to apply the fundamental theorem of calculus that you wanted to see that it is an anti-derivative of some other function.

But now for stochastic calculus here that fundamental theorem of calculus does not hold because I mean in that form, so what is substituting is the Ito's formula because that actually, you know it shows that okay, what is the correct thing to look at. Okay so Ito's formula is the thing what you are going to use for this.

Okay so, assuming that S_t has a I mean this has a solution then we use exactly the way we used to think in for solving ODE that since you know the unknown is multiplied here, so we are going to take log of these things, okay. So, we do exactly the same manner f of S_t we define, f of S_t is log of S_t and then this is not defined when S_t is negative correct. So, we can only define these for time t which is less than the exit time of the positive domain, okay.

So, the first time when S_t becomes negative, I mean non-positive 0 or negative, okay so exit of the upper half plane okay exit time of the upper half plane. So, for all t which is before the exit time then it is well defined then I can define it okay, so after assuming that this equation has a solution I am considering f of S_t and apply and I am going to apply Ito's formula on this okay.

So, here dS , the quadratic variation of S_t also I am calculating as I have indicated earlier that it would be $\sigma^2 S_t^2 dt$. So, the increment of quadratic variation of S is $\sigma^2 S_t^2 dt$ okay. Now I am since I know all these things, so I can apply now Ito's formula. You remember that for applying Ito's formula of a function of a process I need quadratic variation of the process, correct?

So, far I just knew the quadratic variation of Brownian motion okay, but using that product table, I now write down this is the quadratic variation of S_t okay, so we are going to now use the Ito's formula here, $d \log S_t$ is equal to okay, now f the Ito's formula, the derivative comes f prime $S_t dS_t$ plus half times double derivative of f S_t , and then the quadratic variation, so quadratic variation is $\sigma^2 S_t^2 dt$. Okay this is just direct application of Ito's formula on this.

So, now here we compute. So, f of S_t is $\log S_t$, so derivative is $1/S_t$ therefore, and here double derivative is $-1/S_t^2$ okay, so that thing would come, but S_t^2 and this S_t^2 would cancel each other, but I would retain the negative sign, so minus $\sigma^2 dt$ half is also there, half is there.

So, from this I am going to get this and from here this dS_t , I already know this is the form, so I am going to write down dS_t is equal to $\mu S_t dt + \sigma S_t dW_t$ okay, so take here, okay. Here this subscript t is missing, $1/S_t \sigma S_t dW_t + \mu S_t dt$. Now here I have S_t

and I have S_t here and anyway my S_t 's are positive. So, you know these things all makes sense we can cancel these S_t 's, etc.

So, we get a very nice formula here. So, very nice thing, so here I just have $\int_0^t \sigma dW$ from this part, from this part I have μ and from here minus half σ^2 , so $\mu - \frac{1}{2}\sigma^2$ by dt . So, that is the form. Okay so, now I can integrate both sides from 0 to t . So, if we integrate this from 0 to t , I would get $\log S_t - \log S_0$. That $\log S_0$ I transfer to the right hand side.

So, $\log S_t$ is equal to $\log S_0$ plus integration of this is very easy, the σ times W_t integration of this, this is just constant $\mu - \frac{1}{2}\sigma^2$ times t . And now, I take exponential both sides. So, it is S_t is equal to S_0 times e to the power of this term, $\sigma W_t + \mu - \frac{1}{2}\sigma^2$ by t okay. But t is running from 0 to τ , okay.

I cannot assure that this is the expression for whole positive real line because this thing is only makes sense when t is less than τ . Now, if I can prove that τ is infinity with probability 1, we would be done. So, we need to do that okay, we need to do this.

(Refer Slide Time: 19:55)

- ⑩ Now it remains to show that $P(\tau(\omega) < \infty) = 0$.
- ⑪ Let ω be such that $\tau(\omega) < \infty$ and the solution exists for $t < \tau(\omega)$.
- ⑫ Let $t \uparrow \tau(\omega)$, then using the continuity of $\{S_t\}_{t \geq 0}$ at $\tau(\omega)$,
- ⑬

$$\begin{aligned} 0 &= \lim_{t \uparrow \tau(\omega)} S_t = S_{\tau(\omega)^-} \\ &= S_0 \exp(\sigma W_{\tau(\omega)^-} + (\mu - \frac{\sigma^2}{2})\tau(\omega)^-) \\ &= S_0 \exp(\sigma W_{\tau(\omega)} + (\mu - \frac{\sigma^2}{2})\tau(\omega)) \neq 0 \end{aligned}$$

which is a contradiction.

- ⑭ This proves that for almost no path $\tau(\omega) < \infty$.
- ⑮ Or in other words

$$S_t = S_0 \exp(\sigma W_t + (\mu - \frac{\sigma^2}{2})t) \quad \forall t > 0.$$

- ① We can use Itô's formula to solve

$$dS_t = \mu S_t dt + \sigma S_t dW_t.$$

- ② Let us assume that the above equation has a continuous solution with probability 1.
- ③ Let $f(S_t) := \log(S_t)$ for $t < \tau(\omega)$, where $\tau := \min\{t > 0; S_t \leq 0\}$. Then using $d(S_t) = (\mu S_t dt + \sigma S_t dW_t)^2 = \sigma^2 S_t^2 dt$,
- ④

$$\begin{aligned} d \log S_t &= df(S_t) = f'(S_t) dS_t + \frac{1}{2} f''(S_t) S_t^2 \sigma^2 dt \\ &= \frac{1}{S_t} (\sigma S_t dW + \mu S_t dt) - \frac{1}{2} \sigma^2 dt \\ &= \sigma dW_t + (\mu - \frac{\sigma^2}{2}) dt. \end{aligned}$$

- ⑤ $\log S_t = \log S_0 + \sigma W_t + (\mu - \frac{\sigma^2}{2})t$
 $\implies S_t = S_0 \exp(\sigma W_t + (\mu - \frac{\sigma^2}{2})t) \quad \forall t < \tau.$

So, it remains to show that probability that tau omega is finite is 0 okay. So, you are going to show that okay tau omega finite that event would happen with probability 0. So, now let omega be such that tau omega is finite, okay. So, I would like to show that this class of omega is coming for 0 measure set. Let omega be such that tau omega is finite and the solution exists for, you know up to tau omega.

So, I cannot say t is equal to tau up to tau omega. So, let t, now we are letting t tends to tau omega okay, we are going to take the limit okay and then we are also going to use continuity of S t. So, here we are actually do not need to do much here. So, let us see what we do. So,

here since S_t is a continuous path solution. So, τ_ω is the time when S_t becomes 0 or negative, but before that it was positive.

So, if it has a continuous path at τ_ω it should be 0, correct, it cannot be negative, okay. So, here $\lim_{t \rightarrow \tau_\omega^-} S_t$ that is $S_{\tau_\omega^-}$. So, that is 0. So, now for this we know the expression of S_t , we are writing that and allowing this thing t is represent τ_ω .

Since all these functions are continuous functions because e^x exponential function okay, these are all continuous function. So, as t tends to $t = \tau_\omega$, this converges to here for that each and every ω . So, it S_0 into e to the power of σW_{τ_ω} minus and also Brownian motion is continuous actually I can write down τ_ω also here. So, $\mu - \frac{\sigma^2}{2} \tau_\omega$.

So, this basically this goes to τ_ω , the minus sign is not important here is makes no sense τ_ω . So, here is this τ_ω . So, this is all I mean same thing is written actually without minus sign okay. Now, this thing we have obtained, but we have assumed that τ is finite, so e to the power of some quantity here okay, some quantity which is almost surely, you know Brownian motion for every ω you get a finite value, correct.

Okay so, here this is non-zero surely because here this is just e to the some number, so that is that cannot be 0. So, we get a contradiction. So, what does it imply? So, this contradiction proves that so for almost no path we can see that τ_ω is finite. We have arrived at this contradiction by assuming that τ_ω is finite, correct. So, then I have arrived at this contradiction.

So, τ_ω is obtained by the exit time of the solution. So, almost no solution paths are such that τ_ω can be found finite or in other words when you are looking for solution S_t is equal to S_0 into e to the power of σW_t plus $\mu - \frac{\sigma^2}{2} t$ for all t positive.

So, this is see, I mean this is geometric Brownian motion by definition because here I have Brownian motion times some constant here and here I have a drift term okay, so geometric

Brownian motion with drift. So, the definition when we have visited that α and β , so this is α and this is β , okay this is β , good.

Now, when you, one obtains this one can say that okay I have obtained these by assuming that it has a solution, but how can you be sure that it has actually solution, but okay now I have this formula. Now from these you use Ito's formula on this function because this exists of course because Brownian motion is there it means the step here given okay and then we obtain that this solves that SDE is very straightforward to check that this actually solves that SDE.

Okay so, this gives you an idea that how one can solve a given SDE, okay. Just it is not very different from the things what you have done in your ODE course in undergrad level. But only thing is that the formula is different. And, I mean, here is some kind of you know, analysis which one has to be careful, one takes log function correct. So, this is nothing other than that.

Okay otherwise it is not much difficult thing. Okay so, next what we do is that, we would check what is the utility of this process, okay. So, this process is actually very popular for its application in modeling stock price market okay and that is also a field which gives rise to some other processes for which one may not actually find out such kind of closed solution, correct. So, this is no solution is in closed form.

And then for those applications, it also becomes very important to actually develop a theory for stochastic differential equations. So, we call these equations as stochastic differential equation because this is of course differential equation with some differentials involved, but it is random correct because the Brownian motions are there.

So, then it becomes important to develop a theory for stochastic differential equation that even one cannot find out one cannot solve the equation in known elementary in terms elementary function. But still can one assure existence of the solution, okay. So, that also becomes important. So, we are going to see those type of examples also.

(Refer Slide Time: 26:33)

Louis Bachelier

- First mathematical model of

market appears in the PhD thesis "Theorie de la speculation" Annales de l'Ecole normale superiure (1900).

- The model failed to capture the positivity of stock price.
- Stock price was modelled as a Brownian motion with drift.
- Brownian motion was independently formulated by Albert Einstein in 1905.

GBM Model

Figure: Fischer Black, Myron Scholes*, and Robert Merton* (*1997 Nobel in Economics)

- The geometric Brownian motion model for stock price (speculative price) was proposed by Paul Samuelson in 1965.
- The model could overcome the non-positivity dispute.
- Black & Scholes (1973) and Merton (1973) found exact expression of price of European call and put option with GBM model.
- Option price satisfies a Cauchy problem with a Parabolic PDE.

First we just recall that what was the starting of the applications of stochastic processes. So, the here the first mathematical model of market appears in PhD thesis of Louis Bachelier. So, it is some known very old picture of Louis Bachelier. This appeared in 1900. So, more than a century before correct, 120 years back.

So, there he actually when he used this, you know I mean he studied market using stochastic process that time no mathematical tools for Brownian motion was existing, okay. I mean the name of Brownian motion was also not common there. However, he used a random walk etc.

Actually he used random walk and then actually he came up with correct formulation Brownian motion in his PhD thesis as a limit of random walks okay.

This is actually 5 years before Einstein's paper on Brownian motion. So, the model, however failed to capture the positive stock price Brownian motion in any way I mean, can go negative. So, as a model, it was pretty much useless for application. However, that was beginning of the effort, that using stochastic process or the tools in probability theory for modeling stock price.

So, he modeled the stock prices using Brownian motion intrigued. Brownian motion was you know independently formulated by Albert Einstein in 1905 and then a long gap okay. So, the geometric Brownian motion what we have just seen now with greater details we have seen actually the SDE for geometric Brownian motion, we have seen the differential geometry Brownian motion, we have seen also how to derive the solution of the equation.

So, these geometric Brownian motion was actually proposed by Paul Samuelson in 1965 to model stock price okay. So, it is nearly, you know 65 years after the work of Louis Bachelier. So, Louis Bachelier try to use this Brownian motion and then geometric Brownian motion was proposed by Paul Samuelson in 1965.

Okay I mean, the long gap is mainly because the Louis Bachelier work was mostly ignored because nobody thought that okay that can be improvised okay

And also the, I mean required tools mathematical tools were also vastly unpopular during this time period, the model could overcome the non-positivity dispute what Bachelier had. But then in 1973 paper, actually this work was done by Black and Scholes early. So, but they published that in 1973 that they used this geometric Brownian motion to model stock price and then did some stochastic analysis to find out price of options. But that is a different thing, what is option, we are not going to details of the definition of these derivatives of stock price.

But that was the first breakthrough in this field and then many researchers become interested to study stochastic process because that gives better insight of pricing of tradable assets, so which is very much real life scenario. So, in the work of Black-Scholes and also followed by

Merton's work, so they have shown that option price satisfies a Cauchy problem with a parabolic PDE, so that they have done.
