Brownian Bridge

In the last tutorial session, we have seen this system of stochastic differential equations. And then we have I mean demonstrated that how the v , the second component behaves over time and then this system of equation actually, you know is used for modeling asset prices, because this v stands for volatility fluctuations which you know moves you know, within some range not a hardbound range, but there is a mean reverting dynamics of the process v . And then this S is model for asset price dynamics in financial market.

Okay, today, we are going to see another stochastic differential equation for which also we have some very nice geometrical pattern and for which you would be able to interpret that we can actually explain the pattern from the equation also.

(Refer Slide Time: 01:24)

Brownian Bridge

- For a pair of scalars a and b , let $X := \{X_t\}_{t \in [0,1]}$ be given by

$$X_t := b + (1-t)(a - b + \int_0^t \frac{1}{1-s} dW_s)$$

where W is a Brownian motion.

- Then $X_0 = a$ and $X_1 = b$ almost surely. Therefore, X is called the Brownian bridge(BB) from a to b .
- We would find out the SDE representation of the BB.
- Clearly

$$\begin{aligned} dX_t &= (1-t) \frac{1}{1-t} dW_t - (a - b + \int_0^t \frac{1}{1-s} dW_s) dt \\ &= dW_t - \frac{X_t - b}{1-t} dt = \frac{b - X_t}{1-t} dt + dW_t. \end{aligned}$$

Okay so, let us start that. So, this is Brownian Bridge, so what is Brownian bridge? So, for a pair of scalars a and b let X which is a stochastic process define for time only between 0 and 1 be given by this equation. So, and then we would call that X is a Brownian bridge from a to b . So, what is the equation, let us look at the equation more carefully. X_t is defined as b plus

$1 - t$ times $a - b$ plus integration from 0 to t of $\frac{1}{1 - s} dW_s$, okay where W is a Brownian motion.

So here, let us understand that, how does this process look like at the end points first? So, here t is running between 0 and 1, so endpoints are time 0 and time 1. At time 0, we can put 0 here. So if you place 0 here, this integration vanishes. On the other hand here, I would get $1 - 0$, so that is 1 only. So, I would get $a - b$ here, but this would not be there.

So, $a - b$ but b already present here. So, $b + a - b$ would give me a , that means at times 0, X_0 is equal to a . Now, if we want to understand that, how does it look, you know at time t is equal to 1, then we have to place t is equal to 1 here, here. However, for this whatever it is, so t is equal to 1 but here t is equal to 1 makes everything 0 correct, $1 - 1$ will be 0.

So, this part vanishes, this part would not be there and we get to b , correct. So, X_t is equal to b then X_1 , so X_1 would be b . So, that means this process at time 0 is a , at time 1 is b okay. And this process is called Brownian bridge between a and b . Why do we call it Brownian? Because it is coming from Brownian motion that is giving there randomness and why is it bridge because it is bridging between these 2 points a and b .

However, these 2 points could be at the same points also. So, it will make bridge. Okay now, we would like to understand or derive what stochastic differential equation for this process. So, this is the definition of the process, but we would see that you derive actually the stochastic differential equation for which this is a solution.

So, here this is the comment that X_0 is going to a , X_1 is equal to b almost surely, so this is called Brownian bridge from a to b . So, we would find SDE representation, but that is very easy. So, what we do? We write down dX_t here, so differential we take from both sides. So, dX_t is equal to, so this is constant, so it vanishes.

I would get from here $-dt$ and then this product correct so, $-dt$ times this part and $1 - t$ times again the differential of this that is $\frac{1}{1 - t} dW_t$. So, that we write down here. So, first we write down this thing that it is $1 - t$ times, so here $\frac{1}{1 - t} dW_t$ and then minus sign here the whole thing $a - b$ plus integrations from 0 to t of $\frac{1}{1 - s} dW_s$

minus $s dW_s$ and the here from here minus dt . So dt and minus sign is here, okay just taking differentials of both sides I get this.

Now just simplification, so here we can understand that this term can be rewritten as X_t minus b minus 1 minus t , okay so that we do here. So, this a minus b this thing is X_t minus b divided by 1 minus t . So X_t minus b 1 minus t divided by minus by 1 minus t . Here minus sign is there, so I get this b minus X_t divided by 1 minus t .

Okay, so, dW_t , so from here we get dW_t here minus X_t minus b divided by 1 minus t dt and then adjusting the negative sign, we get this very nice equation okay, very short equation dX_t is equal to b minus X_t divided by 1 minus t dt dW_t . So, in this equation, we see 2 terms.

(Refer Slide Time: 06:12)

Asset Price Dynamics

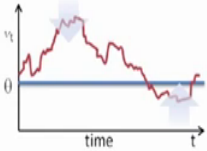

$$dS_t = \mu S_t dt + \sqrt{v_t} S_t dW_t, S_0 > 0$$

$$dv_t = \kappa(\theta - v_t)dt + \sigma\sqrt{v_t}dW'_t, v_0 > 0$$

$$dW_t dW'_t = \rho dt.$$

κ is speed, θ is long run mean, and σ the volatility.
 Feller Condition: $\sigma^2 < 2\kappa\theta$ assures non-negativity of v .
 Square integrability of S :
 $\sigma \leq \frac{\kappa}{(2\rho + \sqrt{2})^+}$

And we relate that we also have obtained that 1 term is dt term, another is dW_t term, okay. So, in general ODE, you just say that dX_t is equal to $f(X_t)$ okay and then that denominator dt if you write down that means you write want to see ODE as integral equation then you get dX_t is equal to $f(X_t) dt$, okay.

But here you have extra additional term this Brownian motion that is giving you the randomness uncertainty and that is why we are calling this stochastic differential equation.

(Refer Slide Time: 06:47)

Brownian Bridge

- For a pair of scalars a and b , let $X := \{X_t\}_{t \in [0,1]}$ be given by

$$X_t := b + (1-t)(a - b + \int_0^t \frac{1}{1-s} dW_s)$$

where W is a Brownian motion.

- Then $X_0 = a$ and $X_1 = b$ almost surely. Therefore, X is called the Brownian bridge (BB) from a to b .
- We would find out the SDE representation of the BB.
- Clearly

$$\begin{aligned} dX_t &= (1-t) \frac{1}{1-t} dW_t - (a - b + \int_0^t \frac{1}{1-s} dW_s) dt \\ &= dW_t - \frac{X_t - b}{1-t} dt = \frac{b - X_t}{1-t} dt + dW_t. \end{aligned}$$

- Hence BB satisfies $dX_t = \frac{b - X_t}{1-t} dt + dW_t$ with $X_0 = a$.

Okay so, here also we are getting that, that dX_t is equal to $b - X_t$ divided by $1 - t$ plus dW_t . So, that is the equation and where t is ranging from, you know 0 to 1 and initial condition is a . So, this is the SDE for Brownian bridge from a to b . Now, we are going to study few more other properties of Brownian bridge.

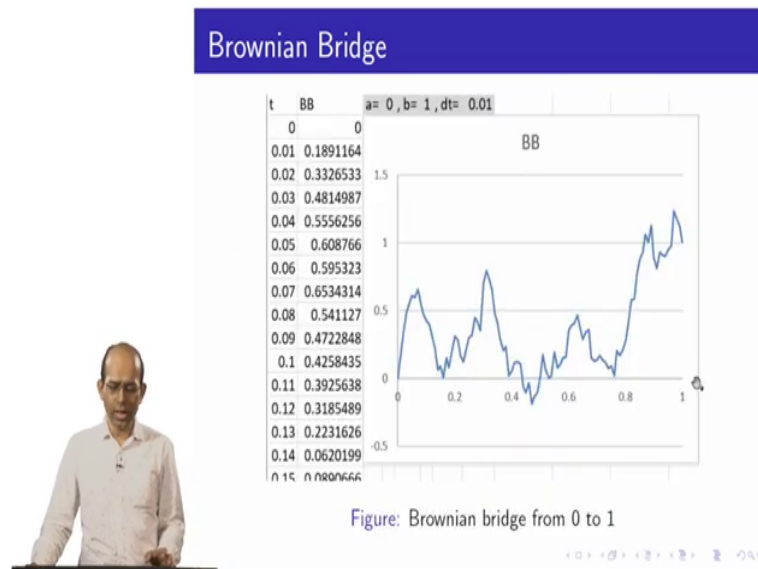

So, imagine that I have a Brownian bridge from a to b where a and b are not equal this b could be larger than a or could be smaller for without losses let us assume that is larger than a . Then this you know X_t as it shows here it is continuous because it is integration with respect to Brownian motion that integral we have already seen that it is continuous martingale correct.

So, it is continuous and this is continuous, so this is actually having continuous path almost surely. So, if the process goes from a to b , then any point between a and b say for example c should be touched by the process at some time τ . So now, whatever the random time τ at which the process hits the level c which is in between a and b , so from the time onward if I look at the process okay, then this is like connecting c to b okay, is that a Brownian bridge?

Answer is not pretty yes because after all Brownian bridge by definition should be between time 0 to 1, here time is maybe smaller than 1. So, one can ask that okay, if I change time in appropriate manner, so that after scaling of the time I get from that point, τ to 1 is like, you know, 0 to 1 interval, if I do this mapping.

After that mapping, can I make it a Brownian bridge? The answer is yes, we can do that. So, that is a thing I am showing it here. So, we do not need anything other than just manipulations just calculus. So, I find that okay that is very interesting example for tutorial that one would be confident there, how does this manipulations do happen and whatever we have learnt earlier can be used here to achieve this, okay.

(Refer Slide Time: 09:22)

So, before that let us see bridges, you know this pattern and maybe simulation, if I have time I would come back to the simulation how to simulate, that means how did I actually compute this particular realization of Brownian bridge. So, here this is a Brownian bridge from 0 to 1, so, a here is 0, b here is 1 okay and time is horizontal axis and then this is actually, I mean simulated from the SDE.

Okay the stochastic differential equation, what we have obtained from that we have stimulated. One can actually stimulate from their direct definition also, but here I have simulated from the SDE to check that how nicely it is coming. Okay so if I have time I would come back to the simulation procedure also.

So, let us go back to our question that from point c to b, so it is at time tau, how or what is the appropriate time change so that the new process can also becomes under the new scaling becomes a Brownian bridge. So that was the question.

(Refer Slide Time: 10:37)

Brownian Bridge

- Let $a \neq b$ and c is in between a and b .
- Since a BB has continuous path, it hits c at time $\tau \in (0, 1)$ a.s.
- Define $Y_t := X_{\tau+t}$ for $0 \leq t \leq 1 - \tau$.
- Then using $W'_t = W_{t+\tau}$, a Brownian motion, $\forall 0 < t < 1 - \tau$

$$dY_t = \frac{b - Y_t}{1 - t - \tau} dt + dW'_t, \quad Y_0 = X_\tau = c, Y_{1-\tau} = X_1 = b.$$

- Define for every $t' \in [0, 1]$,

$$Z_{t'} := \frac{Y_{t'(1-\tau)} - b + (b-c)(1-t')}{\sqrt{1-\tau}} + c + (b-c)t', \quad \Rightarrow Z_0 = c.$$

- Now consider $W''_{t'} := \frac{1}{\sqrt{1-\tau}} W'_{(1-\tau)t'}$.
- Then W'' is another Brownian motion as
- $d(W'')_{t'} = \left(\frac{1}{\sqrt{1-\tau}} dW'_{(1-\tau)t'}\right)^2 = dt'$.

Brownian Bridge

- For a pair of scalars a and b , let $X := \{X_t\}_{t \in [0,1]}$ be given by

$$X_t := b + (1-t)(a-b) + \int_0^t \frac{1}{1-s} dW_s$$

where W is a Brownian motion.

- Then $X_0 = a$ and $X_1 = b$ almost surely. Therefore, X is called the Brownian bridge (BB) from a to b .
- We would find out the SDE representation of the BB.
- Clearly

$$\begin{aligned} dX_t &= (1-t) \frac{1}{1-t} dW_t - (a-b) + \int_0^t \frac{1}{1-s} dW_s dt \\ &= dW_t - \frac{X_t - b}{1-t} dt = \frac{b - X_t}{1-t} dt + dW_t. \end{aligned}$$

- Hence BB satisfies $dX_t = \frac{b-X_t}{1-t} dt + dW_t$ with $X_0 = a$.

So, assume that a is not equals to b and c is in between a and b . So, since Brownian bridge has continuous path, it hits at, you know c at some point τ , so hitting time τ , which is of course between 0 and 1 , almost surely it would hit here and then we define Y_t , okay so this is doing, you know step by step time change is equal to defined as $X_{\tau+t}$.

That means Y_0 is equal to X_τ . So, Y is equal to X_τ and then t is running between 0 to 1 minus τ , I cannot talk about t more than 1 minus τ because that is not defined because when t is equal to 1 minus τ , I get X_τ plus 1 minus τ that is X_1 , okay X is not defined for a time more than 1 , so anyway time is here between 0 to 1 minus τ .

So, that shows us the reason that we need to scale the time, okay. The shifting does not help the scaling is required, okay we do that. So, we define one Brownian motion W prime t which is W t plus τ . So, it is just shifted process, so from τ onward.

So, here t is between 0 to $1 - \tau$ okay and then here, what we do? We take dY t is equal to $b - Y$ t divided by $1 - t$. So, this Y t as I have defined here would satisfy this is SDE. So, this we can obtain directly from the SDE, what we have obtained here. So, dX t is equal to $b - X$ t by $1 - t$ dt plus dW t here. So, t plus τ is replaced by this thing Y t correct.

So, if I replace t by t plus τ all the cases, so here I would get $1 - t - \tau$, here I would get W t plus τ , here also t plus τ , but X t plus τ is Y t . So, that we are going to use so you would get that $1 - t - \tau$ and W t plus τ is W prime t , so dW prime t , and here and the numerator you would get $b - X$ t plus τ but X t plus τ is Y t .

So, it get in a numerator $b - Y$ t . So, we get this new SDE for you know, for this process Y , where Y 0 is equal to X τ goes to 0, X τ . And X τ is c by definition of τ . And then Y $1 - \tau$ is X 1 because you know, $1 - \tau$ here is X 1 and X 1 is b by definition of X .

Okay so, we know pretty sure that we understand now Y is just you know, starting at time 0 there at c and at $1 - \tau$, it is a random time there it is touching b but still it is random correct. So, it is not exactly like a Brownian bridge, you have to do something more. There is something more comes here. So, this is our proposal that let us define a process, new process Z .

So, Z of t prime where t prime is between 0 and 1, Z of t prime is defined as this fraction plus c plus $b - c$ times t prime. This fraction in a numerator we have Y t prime $1 - \tau$, see here that earlier, the time interval on which y is defined has the length $1 - \tau$ that is possibly less than 1 okay. So, but t prime is between 0 to 1, so what we are doing is the t prime into $1 - \tau$ we are taking.

So, when t prime is 0, this is Y 0 , when t prime is 1, this you know this time would be $1 - \tau$. So, the whole, you know process Y , you know that is scaled into this. However, we also need to adjust this little more, so Y t prime into $1 - \tau - t$ plus $b - c$

times $1 - t'$ divided by square root of $1 - \tau$. So, this depends on τ of course, I mean that is expected.

So, here τ appears plus c plus $b - c$, t' . It looks little complicated, but it is not that complicated actually this is the natural thing to do actually, because I would like to match it at time 1 to b , so I have subtracted here and then later I have added also because when t' is equal to 1 , you will get b there from that.

So, let us just analyze, what did we obtain here? So, put t' is equal to 0 , both sides, I got Z_0 . So, Z_0 is equal to $Y_0 - b + b - c$. So, this b and this minus b would cancel, so I would get $Y_0 - c$. Y_0 is anyway c . So, $Y_0 - c$ is 0 , so numerator is 0 okay. On the right hand side, I have, here I have get t' is equal to 0 that this factor would vanish, so I would get c . So, Z_0 is equal to c .

Now we see from this definition, what is Z_1 ? So, we would put t' is equal to 1 here, if we put then I would get Y of $1 - \tau$, that is b anyway, so $b - b$, that is 0 . And then t' is equal to 1 , so $1 - 1$ is 0 , so numerator is 0 . And then here t' is equal to 1 if I put then I would get $b - c$, but this c and this minus c would cancel each other so I would get b .

So Z of 1 is b . So, Z is connecting c to b it during the time interval 0 to 1 okay. So, surely this is a very nice candidate for Brownian bridge but any process which connects you know, the 2 points at time 0 and 1 is need not be a Brownian bridge. I mean it should have the similar statistical property also. So, that is the thing we need to check okay. And that is a thing for that we actually have appropriately chosen that denominator, okay.

So, let us see that. So, to prove that this process Z is indeed a Brownian bridge from c to b , what are you going to do? We are going to show that these Z satisfies the stochastic differential equation. So, that stochastic differential equation I mean, this characterization we have already obtained that if a process satisfies this SDE then it is a bridge between a to b , a appears here b appears here.

So, this is the characterization we would consider and then, so now for proving that we need a little more. So, we define another Brownian motion W'' . So, that is defined as $W'' \times t'$ is defined as 1 over square root $1 - \tau$, W' of $1 - \tau$

tau times t prime okay. So, here this why is it a Brownian motion? I mean that is subject to, you know proof, we are going to prove that.

But before that let us see that what happens that here I have changed the time since tau is less than 1, so $1 - \tau$ is smaller than 1. So, this process, you know runs little slowly okay. However, we also when you divide it, you know by square root of $1 - \tau$ smaller number. So, that means we have actually scaled up I mean this fraction is more than 1 okay. So, to prove that this is a Brownian motion what we are going to do is that first we check whether it is a continuous process? Yes, it is a continuous process, the way it is defined since W prime is continuous this is continuous.

And next is that what is its quadratic variation? So, then we are using Levis characterization of Brownian motion that if the quadratic variation is identity function then it is a Brownian motion. So, dW double prime t prime, so that we obtain as we have seen in the last tutorial session that to compute it, we are going to just take the corresponding, you know different square of the differentials for competition.

So, here 1 over square root of $1 - \tau$ and here is the differential is dW prime $1 - \tau$ t prime and the whole square. So, then from here this part I would get 1 over $1 - \tau$ square of the square root is 1 over $1 - \tau$. And for this the quadratic variation of W prime appears and that would be exactly you know since this is Brownian motion it will be $1 - \tau$ times t prime okay, dt prime.

And this $1 - \tau$ what would appear and here in the denominator also you have $1 - \tau$, they would cancel each other and what would remain is just dt prime. So, that justifies as a W double prime defined this way is also a Brownian motion. Okay so this is something we are going to use to obtain an SDE for the process Z , okay.

(Refer Slide Time: 20:51)

Brownian Bridge

- We show that Z is a BB from c to b .

$$\begin{aligned}
 dZ_{t'} &= \frac{dY_{t'(1-\tau)} - (b-c)dt'}{\sqrt{1-\tau}} + (b-c)dt' \\
 &= \frac{1}{\sqrt{1-\tau}} \left(\frac{(b-Y_{t'(1-\tau)})(1-\tau)dt'}{1-t'(1-\tau)-\tau} - (b-c)dt' + dW''_{(1-\tau)t'} \right) \\
 &\quad + (b-c)dt' \\
 &= \frac{1}{\sqrt{1-\tau}} \left(\frac{(b-Y_{t'(1-\tau)})}{1-t'} - (b-c) \right) dt' + dW''_{t'} + (b-c)dt' \\
 &= \frac{-Z_{t'} + c + (b-c)t'}{1-t'} dt' + dW''_{t'} + (b-c)dt' \\
 &= \frac{b-Z_{t'}}{1-t'} dt' + dW''_{t'}, \quad Z_0 = c.
 \end{aligned}$$

Brownian Bridge

- Let $a \neq b$ and c is in between a and b .
- Since a BB has continuous path, it hits c at time $\tau \in (0, 1)$ a.s.
- Define $Y_t := X_{\tau+t}$ for $0 \leq t \leq 1-\tau$.
- Then using $W'_t = W_{t+\tau}$, a Brownian motion, $\forall 0 < t < 1-\tau$

$$dY_t = \frac{b-Y_t}{1-t-\tau} dt + dW'_t, \quad Y_0 = X_\tau = c, Y_{1-\tau} = X_1 = b.$$

- Define for every $t' \in [0, 1]$,

$$Z_{t'} := \frac{Y_{t'(1-\tau)} - b + (b-c)(1-t')}{\sqrt{1-\tau}} + c + (b-c)t', \quad \Rightarrow Z_0 = c.$$

- Now consider $W''_{t'} := \frac{1}{\sqrt{1-\tau}} W'_{(1-\tau)t'}$.
- Then W'' is another Brownian motion as
- $d(W'')_{t'} = \left(\frac{1}{\sqrt{1-\tau}} dW'_{(1-\tau)t'} \right)^2 = dt'$.

So, this is the way we do, so here we show that Z is a Brownian bridge from c to b . So, we show that okay Z satisfy $dZ_{t'}$ is equal to $b - Z_{t'}$ divided by $1 - t'$ plus $dW''_{t'}$ and Z_0 is equal to c . So, this thing okay I am going to explain it first I see that let us look at the result, end result is that Z satisfy this SDE.

So from definition not only definition after the definition we derived that is a characterization of the Brownian bridge using stochastic differential equation. So, there what we have seen is that, if some process satisfies this equation, then we say that this is a Brownian bridge, the

continuous solution of this equation would be the Brownian bridge and is starting from c to b , the bridge from c to b .

So, the proof starts here, that we are having the Z_t prime is equal to this thing and we take the differential of both sides. So, when we take the differentials, you know this would not appear here, but the dY would appear here from here minus dt prime times b minus c would appear here, from here dt prime b minus c would appear.

So, b minus c dt prime appear from that side and here dY_t prime, etc and minus b minus c , dt prime okay. So, I have from here there I have obtained this equation. Now, from here we do more you know, analysis here. So, what we do is that we use the formula for SDE for Y . So, Y itself satisfies one SDE that we have written here. So, we substitute that part.

So, here what dY_t we have we substitute this by the part on the right hand side. However, here it is written in terms of t but there it is different. So, that we have to appropriately change okay. So, here you have t prime into 1 minus τ .

So, here everywhere, wherever I see t I should write down there t prime into 1 minus τ , t prime into 1 minus τ , etc okay. So, here W prime t prime into 1 minus τ that I need to write down here, so that I do here, so b minus Y_t prime into 1 minus τ , and here 1 minus t was there, so I am writing 1 minus t prime into 1 minus τ here and then, so dt I should write 1 minus τ dt prime.

And here so these things and from Brownian motion part I should write dW prime 1 minus τ t prime. So, these are the things we just do. And then these b minus c dt prime I just have written here, sounds good.

Now, next I need to simplify this okay. So first simplification is that we use the definition of W double prime that W prime 1 minus τ t prime is, you know W double prime. So, 1 over this fraction is also there, this is W double prime, so that we use here 1 over square root 1 minus τ is already present and this part is there.

So, these together would give me dW double prime, t prime, from here I am going to get it. And so from here this side, what we are going to get is b minus Y_t prime 1 minus τ see here, a very nice thing has happened, because 1 minus τ and here minus t prime 1 minus

tau, so I can take 1 minus common. If I take 1 minus tau common then it will be 1 minus tau into 1 minus t prime. So, 1 minus t prime stays here and that 1 minus tau cancels with this 1 minus tau.

So, after this simplification, I would get b minus Y t prime 1 minus tau divided by 1 minus t prime okay and here minus b minus c, so, dt prime okay. And then this part I have already seen this term is this term okay as before. Okay so now we back substitute Z, because for Z we have one equation, so this is a formula for Z in terms of Y.

So, here in the denominator, I have 1 over square root of 1 minus tau, and numerator we have this Y term minus b plus b minus c times one minus t prime. So, these are things, but here, when we actually write down this also in the numerator, I would get b minus c into 1 minus t prime as it appears here. So, this would appear on the in the numerator because 1 minus t prime is here, correct.

If I put it in above, I would get that and then this you know Y and minus b also is here. So, only the sign is negative, here I had plus b minus c into 1 minus t prime here we get minus b minus c into 1 minus t prime and only the sign is negative. So, I get minus Z t prime from there, but there are some other terms this term, so this term would go here, so minus Z t prime plus c plus b minus c t prime.

So, plus c plus b minus c t prime okay from here we are getting this numerator. However in the denominator we have 1 minus t prime and this square root of 1 minus tau would not appear because that is that was also already there, right, we have taken care, okay.

So, only 1 minus t prime would remain here and numerator would be this and dt prime as it is and this part was as before I am just rewriting this thing. Now here it is just a matter of you know, manipulation because here we have b minus c dt prime. And then if I put it together, so we take dt prime common, then I would get b minus c into 1 minus t prime from there also. So, the plus sign here, b minus c into 1 minus t prime, but minus sign is there.

So minus t prime into this thing would cancel with this okay. So, what would get that plus b minus c to appear here, but c plus c is here, so this plus c and that minus c would cancel, so I would get only b here. So, b minus Z t prime would remain in the numerator and denominator is 1 minus t prime dt prime and I would have only this more term dW double prime t prime.

So, by this we have finished the proof that the Z satisfies this stochastic differential equation, and therefore Z is a Brownian bridge from c to b okay, thank you.
