Linear Transformation and Matrices

So when we define linear transformations, we saw a lot of matrices coming in as examples of linear transformations. In fact, we saw that any M cross N matrix can be thought of as a linear transformation from \mathbb{R}^n into \mathbb{R}^m , and it was vaguely hinted upon that we can associate a metric to any linear transformation in the right setting. So, in this video we will try to make precise what is meant by a matrix associated to a linear transformation, when what is called as the coordinate basis are specified. So, let us begin this video by defining what a coordinating basis is.

(Refer Slide Time: 1:03)

Coordinate Basis: Let V be a finite dimensional vector space. We say that a sequence of vectors (v_1, \dots, v_n) is a co-ordinate basis/ordered basis if the sequence forms a basis of V .

So, let us define what coordinate basis are, so, let us focus on attention on finite dimensional vector spaces here. So, let V be a finite dimensional vector space. Needless to say, all our vector spaces are over the real numbers. So, let beta, okay, let us not define it that way. We say that a sequence of vectors, that is all those vectors, sequence of vectors v_1 to v_n , we say that a sequence of vectors is a coordinate basis. Let us also give alternate name to it, it is also called ordered basis. If this sequence forms a basis of V .

So, let us just try to understand what this definition says because it does not seem like it says much, but that is not the case. We start off with a set say v_1, v_2 upto v_n , which is both linearly independent and a spanning set it turns out to be a basis. When we speak about an ordered basis or a coordinate basis, we are concerned about the order in which we are considering the basis elements. So, in this particular definition you should observe that we are always considering a sequence of vectors v_1, v_2 up to v_n .

So in other words, we can talk about the first vector, the second vector, third vector, n th Vector and so on. Which we could not have done when we just talked about a basis because there was no inherent order which we were referring to in the definition of our basis. So, from your knowledge of real analysis, you would realize that if two elements in a sequence are interchanged, the sequence has technically changed, so that is exactly what will reflect here as well. If the order in which we considered the basis change, the coordinate basis changes even though the vectors need not have change. So, let us give a few examples to illustrate all that we just saw.

(Refer Slide Time: 4:14)

Examples: In \mathbb{R}^3 , let $\beta = (1, 0, 0), (0, 1, 0), (0, 0, 1)$.

The β is a coordinate basis of \mathbb{R}^3 .

Let $\beta' = (0, 1, 0), (1, 0, 0), (0, 0, 1)$. Then β'

is a coordinate basis (different from β).

So examples, the simplest example should be in say, let us go to \mathbb{R}^3 , \mathbb{R}^2 will be too simplistic to talk about the change in order. So in \mathbb{R}^3 let β be the, so sometimes the Greek alphabets are used to denote ordered basis or coordinate basis. So β let this be the sequence of vectors, 1, 0,

0, 0, 1, 0 and 0, 0, 1. From whatever we have seen till now, we know that the vectors 1, 0, 0, 0, 1, 0 and 0, 0, 1 form a basis and in this order beta is a coordinate basis of \mathbb{R}^3 .

As pointed out just a couple of minutes back, if we change the order, let beta prime be a new collection or new sequence which is obtained by say interchanging the first and the second vector. So, let this be 0, 1, 0, 1, 0, 0, 0, 0, 1. Then beta as a set, the collection of these three vectors are no different from the collection of vectors which we get from beta. However, we are not just looking at data sets, we also do how an order of the vectors that is being considered in mind and therefore beta prime, then beta prime is a coordinate basis.

It is not just a coordinate basis, it is a coordinate basis which is different from beta, we just changed the order and we still treat it as a different ordered basis. So why are we doing all this? So, this does not seem like a property which we should keep notice of with so much care that is how it might sound in the first site. However, what we will see now, we will illustrate that there is a reason why all this is being done. So, this is a coordinated basis.

(Refer Slide Time: 7:06)

Coordinate vector w.r.t a coordinate basis.

Let $\beta = (v_1, \dots, v_n)$ be a coordinate basis of V .

Let $v \in V$. Then, by a result proved earlier,

$$v = a_1 v_1 + \dots + a_n v_n \text{ uniquely for some scalars}$$

$$a_1, \dots, a_n \in \mathbb{R}.$$

So, let us also know look at what is a coordinate vector corresponding to a with respect to a basis coordinate basis, then we will proceed. Coordinate vector with respect to a coordinate basis. So, let v again the same setup above v be a finite dimensional vector space. Let us say it is of dimension n and let beta be equal to v_1 to v_n be a ordered basis or a coordinate basis. So ordered basis is an equally popular term in literature of capital V of finite dimensional vector space.

Then, every vector in so let v so the small v vector in capital V and by one of the resellers we have early to that, we know that every vector in capital V can uniquely written as a linear combination of v_1, v_2 up to v_n . Then, by result proved earlier, v can be written as $v = a_1v_1$ plus dot, dot, dot a_nv_n uniquely for some scalars a_1, a_2 up to a_n in \mathbb{R} .

(Refer Slide Time: 9:05)

Let $v \in V$. Then, by a result proved earlier,
 $v = a_1v_1 + \dots + a_nv_n$ uniquely for some scalars
 $a_1, \dots, a_n \in \mathbb{R}$.
 Then we say that the column vector $\begin{pmatrix} a_1 \\ \vdots \\ a_n \end{pmatrix}$ is

the coordinate vector of v relative to β and is denoted
 $[v]^\beta$.

Then, we say that the column vector a_1, \dots, a_n is the coordinate vector. Coordinate representation of v with respect to our relative to β and is denoted $[v]^\beta$, it is not T, v and a superscript β . So, the moment we have a, ordered basis there is a v_1, v_2 up to v_n in that order, then because it is a basis we will be able to write v as a unique linear combination of v_1, v_2 up to v_n . And let us say this is the linear combination that we have a_1v_1 plus a_2v_2 plus up to a_nv_n . In the column vector a_1 to a_n is called the coordinate vector of v relative to the coordinate basis β and its notation is this $[v]^\beta$.

(Refer Slide Time: 10:49)

Example: Let $\beta = (e_1, e_2, e_3)$ be an ordered basis of \mathbb{R}^3 . Consider $v = (1, 2, 3)$

$$v = 1 \cdot e_1 + 2 \cdot e_2 + 3 \cdot e_3 \quad \text{Therefore } [v]^\beta = \begin{pmatrix} 1 \\ 2 \\ 3 \end{pmatrix}$$

Let $\beta' = (e_2, e_1, e_3)$. Then

$$v = 2f_1 + 1f_2 + 3f_3 \quad \text{Then } [v]^{\beta'} = \begin{pmatrix} 2 \\ 1 \\ 3 \end{pmatrix}$$

Example, again, let us go back to the example we have been considering. Let Beta be equal to the let me write it as e_1, e_2, e_3 for the standard basis be an ordered basis of \mathbb{R}^3 , recall that e_1, e_2, e_3 are vectors with one in the, say for even it is one in the first coordinate and zeros in the other coordinates e_j similarly is always defined as one in j coordinate and zero in the remaining coordinate.

So if it is \mathbb{R}^3 , we are looking at three, three, tuples three vectors are three coordinates rather. So, consider a vector v , let us arbitrarily take a vector v and let us look at the vector 1, 2, 3 simplest vector that we can not the simplest vector but as a very simple vector. What is v in terms of e_1, e_2, e_3 ? v is then equal to one times e_1 plus two times e_2 plus three times e_3 .

This is v , as a unique linear combination of v standard basis, and therefore v beta is represented by one, two and three. Suppose, we change the order, let beta be equal to e_2, e_1 and e_3 like we had done earlier. Then what do we know about v ? Then v , so let us call it now this to be f_1 let us call this f_2 and let us call this f_3 . Then v is equal to two times f_1 plus one times f_2 plus three times f_3 . I have just changed beta to beta prime here because beta was already taken. Then, our coordinator presentation, coordinate vector of v with respect to beta prime will then be given by 2, 1, 3. Note that this and this are not the same. So the columns which represent our given vector with respect to the two basis, two coordinate basis, have not

changed and that is the main reason why we are interested in the order. The order is not the only thing that might change.

(Refer Slide Time: 13:51)

$$v = 2f_1 + 1f_2 + 3f_3 \quad \text{Then } [v]^{\beta'} = \begin{pmatrix} 2 \\ 1 \\ 3 \end{pmatrix}$$

$$\gamma = \left(\overset{g_1}{(1, 2, 3)}, \overset{g_2}{(1, 0, 1)}, \overset{g_3}{(1, 1, 0)} \right)$$

Check that γ is a coordinate basis. Then (Check!)

$$v = 1g_1 + 0g_2 + 0g_3.$$

$$[v]^{\gamma} = \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix}$$

For example, what is the vector we start with? It was 1, 2, 3. Now let us complete 1, 2, 3 into some basis. It will certainly have a 1, 0, 1 and 1, 1, 0 these three you can check is a basis for sure in this order. Let us consider gamma to be in this order.

Then check that gamma is a coordinate basis or just a basis, not just a spanning set it is also linearly independent. If it is not needed to check both, because it is a set which contains three elements in a dimension three vectors space and therefore if it is either linearly independent or linearly or spanning set, it will be a basis, because other will be naturally satisfied.

So v can then be written as then again check that v which is our 1, 2, 3 is nothing but, so let us call this ef , let us call g_1 this is g_2 and let us call the g_3 . I should I just call it B_1, B_2 and B_3 , It does not matter, anyway. This is going to be one times g_1 plus zero times g_2 plus zero times g_3 and therefore the vector v 1 is in terms of this gamma coordinate vector of v relative to the coordinate basis gamma will nothing be, will be nothing but 1, 0, 0. So as you can see based on the choice of a basis, the coordinator vector of the given vector with respect to the basis will turn out to be quite, varying actually quite varying. In this case it was 1, 2, 3 it was 2, 1, 3 in the second case when we picked gamma to be 1, 2, 3, 1, 0,

1 and 1, 1, 0 it turns out be 1, 0, 0, so changes quite a lot. So the order and the basis that is contributed a lot. So let us look at more examples.

(Refer Slide Time: 16:32)

Example: Let $\mathcal{P}_n(\mathbb{R})$ be the polynomial vector space of degree $\leq n$.

Let $\beta = (1, x, x^2, \dots, x^n)$ be a co-ordinate basis

Let $p(x) = x^2 + 2x + 1$.

Then $[p(x)]^\beta = \begin{pmatrix} 1 \\ 2 \\ 1 \\ 0 \\ \vdots \\ 0 \end{pmatrix}$

Focus on $\mathcal{P}_2(\mathbb{R})$.

Another example, so coordinate basis is a simple way to have more complicated vector spaces expressed. Like in the case of \mathbb{R}^n . So this following example will indicate that so let \mathcal{P}_n of \mathbb{R} be a polynomial ring of degree less than or equal to n with coefficients in \mathbb{R} be the polynomial vector space of degree less than or equal to n and we know a particular basis or this particular vector space. Let β be $1, x, x^2, \dots, x^n$ be a coordinate basis in this particular order. If you consider it is a coordinate basis, for coordinate basis of \mathcal{P}_n of \mathbb{R} . Let p of x be a polynomial.

Let us say this is a $x^2 + 2x + 1$, then p of x will have a coordinator, representation, coordinate vector of p of x with respect to β . We will just turn out to be equal to $1 \ 2 \ 1 \ 0 \ 0 \ \dots \ 0$. The $n + 1$ cross 1 vector in a the right here. This is the coordinator plus the coordinate vector of p of x with respect to, but let us just make it a bit more simple. Let us focus on n equal to say 2 , focus on \mathcal{P}_2 of \mathbb{R} .

(Refer Slide Time: 18:39)

$$\begin{aligned} \text{Focus on } \mathcal{P}_2(\mathbb{R}). \quad \beta = (1, x, x^2) \\ [p(x)]^\beta = \begin{pmatrix} 1 \\ 2 \\ 1 \end{pmatrix} \\ \hline q(x) = 4x^2 + 3x + 2 \\ [q(x)]^\beta = \begin{pmatrix} 2 \\ 3 \\ 4 \end{pmatrix} \\ \text{Let } \beta' = (x^2, x, 1) \end{aligned}$$

Then, p of x beta will just turn out to be equal to what was of our p of x , x square plus $2x$ plus 1 and beta, if it is $1x$, x a square, this is going to be x square plus $2x$ plus 1 will be $1 \ 2 \ 1$, okay. Let us now consider q of x to be equal to $4x$ square plus $3x$ plus 2 some other polynomial. That is a symmetric polynomial.

I do not know how to work with. It is a symmetric looking polynomial, at least with respect to this basis. What is q of x with respect to our beta? This is $2 \ 3 \ 4$, you should check this out. Now, beta there is no natural order in which we should be considering these vectors. What if let us beta prime be a polynomials x square, x , 1 in this order. Basically, the reverse order as in beta. This could also have been the order in which we started looking at the basis.

(Refer Slide Time: 18:39)

$$\text{Let } \beta' = (x^2, x, 1) \text{ . Then } [q(x)]^{\beta'} = \begin{pmatrix} 4 \\ 3 \\ 2 \end{pmatrix}.$$

Matrix associated to a linear transformation.

Let V and W be finite dimensional vector spaces and let $\beta = (v_1, \dots, v_n)$ be an ordered basis of V

and $\gamma = (w_1, \dots, w_m)$ be an ordered basis of W .

And then what would be q of x with respect to this β' the coordinate vector of q of x with respect to β' will just turned out to be equal to 4 3 2. So as you can see again, there is also illustrates, this example illustrates two things that p of x can be realized as something like \mathbb{R}^n given a coordinate basis. Once you fix a coordinate basis, we can then represent every element or every vector p of x as a vector as a coordinate vector which is a column vector.

And the second thing is that again, if you change even the order in which the basis elements are being considered the coordinate basis changes and the entire representation, everything is once we fix a basis, alright. So we have spent some considerable amount of time trying to develop the concept of coordinate basis. Now let us move over to a what is meant by a matrix, which can be associated to a linear transformation.

So metrics associated to a linear transformation. So let a V and a W be finite dimensional vector spaces. Dimension of V be say equal to N and dimension of W be equal to N and let us also fix some ordered basis here. So, and let β equal to v_1, v_2 up to v_n be a ordered basis. Let me use the word order basis just for the sake of familiarizing that term that is same as a coordinate basis of V and γ , which is say w_1 to if it m dimensional vector space that will be m vectors in every basis. So, the γ be an ordered basis of w .

(Refer Slide Time: 22:56)

and $\gamma = (w_1, \dots, w_m)$ be an ordered basis of W .

Further, let $T: V \rightarrow W$ be a linear transformation.

Let $v \in V$. Then $[v]^\beta = \begin{pmatrix} x_1 \\ \vdots \\ x_n \end{pmatrix}$

let $[Tv]^\gamma = \begin{pmatrix} y_1 \\ \vdots \\ y_m \end{pmatrix}$.

We would like to explore

Further, let T be a map from v to w which is a linear transformation. Let T from v to w be a linear transformation. So now, we are curious about what would be the way in which the coordinate vector corresponding to a vector v in capital V and the coordinate vector corresponding to Tv in capital W with respect of γ , how will they interact with each other? That is the question we would like ask. Let us write down the question more specifically. Let v be an arbitrary vector let fix a vector v in capital V .

Then every vector has a coordinate presentation. The coordinate vector of v with respect to β let it be equal to say something like x_1 to x_n . We in other words this, okay, we will come back to that. This is just telling us that v is x_1v_1 plus x_2v_2 plus x_nv_n . Let Tv with respect to the γ again, the coordinate vector of Tv . Tv is remember vector in w and γ is a coordinated basis here, coordinate basis in capital W of m vectors. Then this will be a column vector of size m cross n . So, let this be denoted by say something like y_1 to y_m . We would like to know how was the column vector x_1 to x_n related to y_1 to y_m .

(Refer Slide Time: 25:03)

We would like to explore how the column vector $\begin{pmatrix} y_1 \\ \vdots \\ y_m \end{pmatrix}$ and $\begin{pmatrix} x_1 \\ \vdots \\ x_n \end{pmatrix}$ are related.

$$[v]^\beta = \begin{pmatrix} x_1 \\ \vdots \\ x_n \end{pmatrix} \Leftrightarrow v = x_1 v_1 + \dots + x_n v_n.$$

$$[Tv]^\gamma = \begin{pmatrix} y_1 \\ \vdots \\ y_m \end{pmatrix} \Rightarrow T\alpha = y_1 w_1 + \dots + y_m w_m$$

So, we would like to explore, how the column vector y_1 to y_m and the column vector x_1 to x_n are related, clearly the relationship has to be through our given linear metric, linear transformation T . Let us look at that again, so v with respect to β being equal to x_1 to x_n implies it is statement, v is equal to $x_1 v_1$ plus $x_2 v_2$ plus up to $x_n v_n$.

We also know that Tv is y_1 to y_m with respect to γ and that tells us that Tv is equal to $y_1 w_1$ plus $y_2 w_2$ plus up to $y_m w_m$, but we know that with respect to a given basis, the represent the linear combination of the basis will be unique to give us the vector Tv . If we can realize Tv as a linear combination of w_1 to w_m in some other manner, the coefficients have to be equal component wise. So, let us just give the first one a name star.

(Refer Slide Time: 26:43)

(*) gives us

$$\begin{aligned}Tv &= T(x_1v_1 + \dots + x_nv_n) = x_1Tv_1 + \dots + x_nTv_n \\ &= x_1(a_{11}w_1 + a_{21}w_2 + \dots + a_{m1}w_m) \\ &\quad + x_2(a_{12}w_1 + a_{22}w_2 + \dots + a_{m2}w_m) \\ &\quad \vdots \\ &\quad + x_n(a_{1n}w_1 + \dots + a_{mn}w_m).\end{aligned}$$

where $Tv_j = a_{1j}w_1 + \dots + a_{mj}w_m.$

Star when we apply T to star, star gives us the following. Tv is equal to T of the right hand side which is T of x_1v_1 plus up to x_nv_n , but recall that T is linear transformation and this will just turn out to be x_1 times Tv_1 to plus up to x_n times Tv_n by the vary properties of a linear transformation, but then each of these Tv_i are vectors in capital W, so let us just write it down as a linear combination of vector w_1 to w_m each of them. So, this will just turn out to be equal to x_1 times let us write Tv_1 in terms of the vectors w_1 to w_m .

So, this will just turn out to be $a_{11}w_1$ plus $a_{21}w_2$ plus $a_{m1}w_m$. Observe that the second index corresponds to v_1 and the first index corresponds to the running w_1, w_2 up to w_m . Similarly, Tv_2 can be written as a_{12} remember that this is corresponding to the second index corresponding to the vector v_2 . So this and the first one corresponding to w_1 . So this is going to $a_{22}w_2$ plus $a_{m2}w_m$.

And x_3 can be written, similarly finally x_n times the first vector again, remember the index is corresponding to the w_1 and the second one corresponding to v_n and, so this will be $n w_1$ plus dot dot dot $a_{mn}w_m$. This is what? Tv can be, this is how Tv can be written as. So, were let me just write down, Tv_j is equal to $a_{1j}w_1$ plus dot dot dot $a_{mj}w_m$ each of the v_j can be written like this. Let me just maintain this because now we can rewrite this.

(Refer Slide Time: 29:44)

$$T x_n (a_{1n} w_1 + \dots + a_{mn} w_m).$$

$$\text{where } T_{ij} = a_{ij} w_1 + \dots + a_{mj} w_m.$$

$$\therefore T v = (x_1 a_{11} + x_2 a_{12} + \dots + x_n a_{1n}) w_1 + (x_1 a_{21} + x_2 a_{22} + \dots + x_n a_{2n}) w_2$$

$$+ \dots + (x_1 a_{m1} + x_2 a_{m2} + \dots + x_n a_{mn}) w_m$$

$$\begin{pmatrix} y_1 \\ \vdots \\ y_m \end{pmatrix} = [T v] = \begin{pmatrix} x_1 a_{11} + x_2 a_{12} + \dots + x_n a_{1n} \\ \vdots \\ x_1 a_{m1} + x_2 a_{m2} + \dots + x_n a_{mn} \end{pmatrix}$$

Therefore, $T v$ if you observed carefully after re-writing this, we will just turn out to be in terms of what would be the combination above in terms of w_1, w_2 up to w_m . If you observe carefully, this is $x_1 a_{11}$ plus $x_2 a_{12}$ plus $x_n a_{1n}$ times w_1 plus $x_1 a_{21}$ plus $x_2 a_{22}$ plus $x_n a_{2n}$ times w_2 dot, dot, dot $x_1 a_{m1}$ plus $x_2 a_{m2}$ plus $x_n a_{mn}$ times w_m . I had just re-written the above in terms of coefficients of w_1, w_2 up to w_m , this is something which you should check just re-written it down.

And therefore $T v$ of gamma, gamma remember was w_1, w_2 up to w_m .

This just can be written down as $x_1 a_{11}$ plus $x_2 a_{12}$ plus $x_n a_{1n}$ dot dot dot $x_n a_{mn}$, sorry $x_1 a_{11}$ plus $x_2 a_{m2}$, I am making some unnecessary mistakes, this will be m_1 plus dot dot dot $x_n a_{mn}$ and remember that this was nothing but y_1, y_2 up to y_m . There we have the right hand side looks quite cumbersome but if we are to recall our knowledge of how matrices multiply, we can write this as is this E metrics multiplication of $a_{11}, a_{12}, a_{1n}, a_{m1}, a_{m2}$ up to a_{mn} .

(Refer Slide Time: 32:14)

$$\begin{pmatrix} \vdots \\ y_m \end{pmatrix} = \begin{pmatrix} \vdots \\ x_1 a_{m1} + x_2 a_{m2} + \dots + x_n a_{mn} \end{pmatrix}$$

$$\begin{pmatrix} y_1 \\ \vdots \\ y_m \end{pmatrix} = \begin{pmatrix} a_{11} & a_{12} & \dots & a_{1n} \\ \vdots & \vdots & & \vdots \\ a_{m1} & a_{m2} & \dots & a_{mn} \end{pmatrix} \begin{pmatrix} x_1 \\ \vdots \\ x_n \end{pmatrix}$$

The above matrix is called the matrix of the linear transformation T w.r.t β and γ and is denoted $[T]_{\beta}^{\gamma}$.

This times x_1 upto x_n . So this is exactly how the coordinate vector of Tv corresponding to γ and the coordinate vector of v corresponding to β are related. It is related by a matrix multiplication. So, this matrix as you can see are having entries of what are a_{ij} , if you recall, a_{ij} is where the coefficient of Tv_i in terms of w_j , the image of the vectors in the coordinate basis of v . When written in terms of the coordinate basis of w uses this particular matrix. So we denote, we call the above matrix. Okay, let me think about how to put it in words, okay.

(Refer Slide Time: 34:03)

$$\begin{pmatrix} y_1 \\ \vdots \\ y_m \end{pmatrix} = \begin{pmatrix} a_{11} & a_{12} & \dots & a_{1n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{m1} & a_{m2} & \dots & a_{mn} \end{pmatrix} \begin{pmatrix} x_1 \\ \vdots \\ x_n \end{pmatrix}$$

The above matrix is called the matrix of the linear transformation T w.r.t β and γ and is denoted $[T]_{\beta}^{\gamma}$.

Observe that $[T]_{\beta}^{\gamma} = \left([T\phi_1]^{\gamma}, \dots, [T\phi_n]^{\gamma} \right)$ is an $m \times n$ matrix.

Examples: $D: \mathcal{P}_3(\mathbb{R}) \rightarrow \mathcal{P}_2(\mathbb{R})$ where $D(p(x)) = p'(x)$

i.e. $\alpha = \{1, x, x^2, x^3\}$ $\beta = \{1, x, x^2\}$ be coordinate...

The above matrix, is called the matrix of the linear transformation T with respect to beta and gamma matrix of the linear transformation T . Observe that this matrix very heavily depends on what beta and gamma are, linear transformation T with the respect to beta and gamma. As I just mentioned, each of the coefficient here are obtained by a writing Tv_j in terms of w_1 to w_m for each of T_j from w_1 to w_m . And this is also denoted T beta gamma.

So, the notation we are following has a name, it is called the Isen Einstein convention, which is used by physicists extensively. Let us not go into that, this is the notation, okay. So, we have defined what the matrix of a linear transformation is when the coordinated basis of the domain and the range of specified, remember that there is this dependence of beta and gamma extensively, this matrix will not make sense if you do not mention what the coordinated basis. So let us look at a couple of examples.

The example about would be, okay, example, it would be a good exercise to go back various examples of linear transformations. Pick your favorite basis on the left and a favorite basis on the right or in other words, a favorite coordinate basis of your domain and a favorite coordinate basis of your range or rather the target vector space and compute the metrics of the linear transformation with respect to the various basis you pick, you will see that the basis can look with the metrics, can look very different.

We will see how they are related later but right now, let us again look at (36:45). One example which I would like to very easily we can show is the differentiation operator, which is from P_3 of \mathbb{R} , P_2 of \mathbb{R} . Let D be a linear transformation where D of p of x is equal to p prime of x . So, what do we know about P_3 of \mathbb{R} and P_2 of \mathbb{R} . We know that P_3 of \mathbb{R} is four dimensional P_2 of three dimensional, we also have at least the knowledge of one coordinate basis here.

(Refer Slide Time: 37:23)

Let $\beta = (1, x, x^2, x^3)$ & $\gamma = (1, x, x^2)$ be coordinate bases in $P_3(\mathbb{R})$ & $P_2(\mathbb{R})$ respectively. Then the matrix of D w.r.t β & γ can be obtained by observing Dv where $v \in \beta$. Check that $[D1]^\gamma = \begin{pmatrix} 0 \\ 0 \\ 0 \end{pmatrix}$
 $Dx = \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix}$, $Dx^2 = \begin{pmatrix} 0 \\ 2 \\ 0 \end{pmatrix}$, $Dx^3 = \begin{pmatrix} 0 \\ 0 \\ 3 \end{pmatrix}$

$$\text{Thus } [D]_{\beta}^{\gamma} = \begin{pmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 2 & 0 \\ 0 & 0 & 0 & 3 \end{pmatrix}$$

$\begin{pmatrix} | & & & | \\ y_m & & & \\ | & & & | \end{pmatrix} \begin{pmatrix} a_{m1} & a_{m2} & \dots & a_{mn} \\ \uparrow & \uparrow & & \vdots \\ [T_{\beta_1}]^\gamma & [T_{\beta_2}]^\gamma & & [T_{\beta_n}]^\gamma \end{pmatrix} \begin{pmatrix} | \\ x_n \\ | \end{pmatrix}$
 The above matrix is called the matrix of the linear transformation T w.r.t β and γ and is denoted $[T]_{\beta}^{\gamma}$.
 Observe that $[T]_{\beta}^{\gamma} = \left([T_{\beta_1}]^\gamma, \dots, [T_{\beta_n}]^\gamma \right)$ is an $m \times n$ matrix.

Examples: $D: P_3(\mathbb{R}) \rightarrow P_2(\mathbb{R})$ where $D(p(x)) = p'(x)$
 i.e. $\beta = (1, x, x^2, x^3)$ & $\gamma = (1, x, x^2)$ be coordi

So let us beta denote the coordinate basis here, which is given by 1, x, x square and x cube and gamma. So this is 1, x, x, square. We are looking like similar problem is, but there problem is in different vectors spaces be coordinate basis in P_3 of \mathbb{R} and P_2 of \mathbb{R} respectively. So one point I

would like to note here is that each of the columns if you observe carefully turns out to be the coordinate vector of Tv . So this is the coordinator vector of the Tv_1 with respect to γ . This turned out to be coordinate vector Tv_2 with respect to γ this turns out to be Tv_n with respect to γ .

So observe here, let me have something here observe that T beta, γ is nothing but this particular matrix where the columns are, Tv_1 with respect to γ . Tv_n with respect to γ . So this is a m cross n matrix. So the columns turns out to be the coordinate vector of the basis vectors from the coordinate basis of beta of v mapped to the w and written in terms of a coordinate basis in w .

So to wright what the metrics of D , so then the matrix of D with respect to beta and γ can be a obtained by looking at what is a D of each of the coordinate basis vectors in, sorry, by looking at what is the, what is D of the vector coordinate basis beta by observing D of v where v belongs to beta. So we can check that $D1$ with respect to γ is $0\ 0\ 0$ the constant is always killed by the differentiation Dx is equal to $1\ 0\ 0$.

Dx^2 is equal to the derivative of x^2 to x , which is $0\ 2\ 0$. And what is the Dx^3 ? This is going to be equal to $3x^2$, which is $0\ 0\ 3$. Thus, matrix of D with respect to beta γ will be $000, 100, 020, 003$. Let us now check that this representation indeed is working. So, for example, let us take an arbitrary polynomial. In fact, let us take the general polynomial of p_3 of R .

(Refer Slide Time: 41:29)

$$\text{Thus } [D]_{\beta}^{\gamma} = \begin{pmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 2 & 0 \\ 0 & 0 & 0 & 3 \end{pmatrix}$$

$$\text{Let } p(x) = a_0 + a_1x + a_2x^2 + a_3x^3.$$

$$\text{Then } [p(x)]_{\beta} = \begin{pmatrix} a_0 \\ a_1 \\ a_2 \\ a_3 \end{pmatrix}$$

$$[Dp(x)]_{\gamma} = \begin{pmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 2 & 0 \\ 0 & 0 & 0 & 3 \end{pmatrix} \begin{pmatrix} a_0 \\ a_1 \\ a_2 \\ a_3 \end{pmatrix} = \begin{pmatrix} a_1 \\ 2a_2 \\ 3a_3 \end{pmatrix}$$

So let p of x be equal to something like say a_0 plus $a_1 x$ plus $a_2 x$ square plus $a_3 x$ cube. Then what is p of x with respect to, so where is this? This is an element in p^3 of r which has β as its coordinate basis which is one x , x square, x cube and this is going to be a_0, a_1, a_2 and a_3 . What is going to be $D p$ of x with respect to γ from whatever we have developed so far.

This is just going to be the matrix multiplication of the matrix above this one, with the coordinate vector of p of x with respect to β . And that will just be equal to $0100, 0020, 0003$ times a_0, a_1, a_2 and a_3 which is going to be $a_1, 2a_2, 3a_3$ as it should be, it should be a three cross one column vector because we are ending up in p^2 of R which is a three dimensional vector space. And by the very definition, what is this? Let us check whether what we have got is right.

(Refer Slide Time: 43:14)

$$[Dp(x)]^\gamma = \begin{pmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 2 & 0 \\ 0 & 0 & 0 & 3 \end{pmatrix} \begin{pmatrix} a_0 \\ a_1 \\ a_2 \\ a_3 \end{pmatrix} = \begin{pmatrix} a_1 \\ 2a_2 \\ 3a_3 \end{pmatrix}$$
$$\Rightarrow Dp(x) = a_1 + (2a_2)x + (3a_3)x^2$$

This implies Dp of x is equal to this is with respect to γ , which is a_1 times 1 plus $2a_2$ times x plus $3a_3$ times x square, which exactly turns out to be our derivative of p of x . What is the derivative of p of x ? It just turn of to be a_1 plus $2ax$ square sorry, $2a_2x$ plus $3a_3 x$ square, which is what we have got here.

Yes, so this, that is work so many many times, we linear transformations that we are considering will not be so straightforward and it boils down to looking for a good basis with respect to which matrix will be nice and easy to work with. That will be a major part of this course. So we will come to all that later.

Right now, the thing to keep in mind is that even any linear transformation, if we have a coordinate basis in the domain and in the target vector space between finite dimensional vector space, of course, then we can talk about a metrics corresponding to these coordinate basis and the linear transformation from v to w , will just turn out to be the matrix multiplication of this matrix with the coordinate vector representing our given vector v with respective corresponding basis to get back the coordinate vector of Tv with respect to the basis of the beta vector space.
