Invertible Linear Transformations and Matrices

So, we have already seen what it means for 2 vector spaces V and W to be isomorphic to each other, we have developed the notion of an invertible linear transformation. In this video we will explore how a linear transformation being invertible reflects upon the matrix associated to it. So, we begin by recalling the definition of an invertible matrix.

(Refer Slide Time: 0:49)

Definition: Let A be an $m \times n$ matrix. We say that an $n \times m$ matrix B is the inverse of A if $AB = I_m$ and $BA = I_n$. We then say that A is an invertible matrix.

Let us start by recollection, definition so that A be an m cross n matrix, we say that a matrix B matrix or rather an n cross m matrix B is the inverse of A if AB is the identity matrix of size m and BA is the identity matrix of size n . So, A is an m cross n matrix, B is an n cross m matrix, if you look at the product of these matrices AB it will just turn out to be an m cross n matrix and we demand that that matrix maybe identity matrix. Similarly, BA is demanded to be the identity matrix of size n , so we say that the matrix B is then an inverse is the inverse of the matrix A . So, we then say that A is an invertible matrix.

(Refer Slide Time: 2:28)

$AB = I_m$ and $BA = I_n$. We then say that A is an invertible matrix.

Exercise: The inverse of a matrix A is unique.

So, an immediate exercise which will follow this is to prove that the matrix A has a unique inverse, the techniques to prove have been developed and used many times. So, you should also use the theorem which was put in the last video wherein we showed that matrix multiplication was or is associated. So, the exercise is to show that the inverse of a matrix A is unique.

So, start off with 2 potential inverses, B and B prime and prove that b is equal to b prime. Alright, so why did we talk about an invertible matrix to begin with, so as it is to be expected, our goal would be to show that an invertible linear transformation as an invertible matrix associated to it.

(Refer Slide Time: 3:40)

Example: Let $A = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & 3 \end{pmatrix}$. Then

$$A^{-1} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & \frac{1}{2} & 0 \\ 0 & 0 & \frac{1}{3} \end{pmatrix}.$$

So, we will come to that before that, let me just for the sake of completion, let me give an example. So, let A be a matrix given by $\begin{pmatrix} 1 & 0 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & 3 \end{pmatrix}$ in the diagonals let me make my life easy here. Then A inverse is equal to $\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1/2 & 0 \\ 0 & 0 & 1/3 \end{pmatrix}$. So this is a familiar concept for you most probably from your high school so need not spend too many.

(Refer Slide Time: 4:19)

$$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & 3 \end{pmatrix}.$$

Theorem: Let $T: V \rightarrow W$ be a linear transformation between finite dimensional vector spaces V & W . Suppose α and β are ordered basis of V & W respectively. Then

T is an invertible linear transformation if and only if

T is an invertible linear transformation if and only if $[T]_{\alpha}^{\beta}$ is an invertible matrix. Moreover, $([T]_{\alpha}^{\beta})^{-1} = [T^{-1}]_{\beta}^{\alpha}$.

Proof: Let $\alpha = (v_1, \dots, v_n)$ and $\beta = (w_1, \dots, w_m)$ be ordered bases of V and W respectively

between finite dimensional vector spaces V & W . Suppose α and β are ordered basis of V & W respectively. Then

T is an invertible linear transformation if and only if $[T]_{\alpha}^{\beta}$ is an invertible matrix. Moreover, $([T]_{\alpha}^{\beta})^{-1} = [T^{-1}]_{\beta}^{\alpha}$.

Proof: Let $\alpha = (v_1, \dots, v_n)$ and $\beta = (w_1, \dots, w_m)$ be ordered bases of V and W respectively.

Let us just spend time on too many examples, let me directly jump into the theorem here, which essentially captures the relationship between invertible linear transformations and invertible matrices. So, let T from V to W , be a linear transformation between finite dimensional vector spaces, V and W . Let us fix in ordered basis α and β of V and W . Suppose α and β are finite that is already known to be finite ordered basis of V and W respectively.

Then the theorem states that T is an invertible linear transformation if and only if the matrix associated to T with respect to β , α and β is an invertible matrix if and only if the matrix T so α β is an invertible matrix, not just this we exactly know what the inverse of this matrix is.

Moreover, the inverse of α β , inverse of this matrix, this turns out to be the matrix associated to the inverse of T , inverse linear transformation of T . This is just the matrix of T inverse not, recall that T inverse will now be a map from W to V , therefore, this will be β α . So, we exactly know what inverse of our matrix corresponding to this linear, this particular linear transformations. So, let us give a proof of this statement. So, we are given α and β .

So, let us once and for all in the context of this proof, let α be equal to say, we want to v_n and β be equal to w_1 to w_m be ordered basis of V and W respectively. Alright, so let us see what our goal is. So, let us first assume that T is an invertible linear transformation. What I am underlining in green and let us prove that the matrix associated to T is an invertible matrix.

(Refer Slide Time: 8:02)

(\Rightarrow) Let T be an invertible linear transformation.
and $T^{-1}: W \rightarrow V$ be its inverse.

Then $TT^{-1} = I_W$ \vee $T^{-1}T = I_V$.

$$[TT^{-1}]_{\beta}^{\beta} = [I_W]_{\beta}^{\beta} = I_m$$

So, let T be an invertible linear transformation. What does it mean to say that a linear transformation is invertible, it means that then there exist an inverse. And we know that the inverse is unique. And suppose T inverse from W to V be its inverse. What do we know about this inverse when composed with T it gives us identity on both sides. So, if you look at TT inverse, then TT inverse is just the identity map of W .

And similarly, T inverse T is just the identity of V by the very definition. We also know that the identity map of W so we know, so let us see what is TT inverse from β to α . So, recall that TT inverse is a map from W to itself and sorry so it will not be β to α , it will be β to β .

This is just the matrix of the identity map with respect to the bases β . And you know what that particular matrix is, the matrix of the identity with respect to β will just turned out to be the m cross m identity matrix. We also have already seen how the matrix corresponding to the linear transformations behave under composition.

(Refer Slide Time: 9:48)

$$[TT^{-1}]_{\beta}^{\beta} = [I_W]_{\beta}^{\beta} = I_m$$

Recall that $[TT^{-1}]_{\beta}^{\beta} = [T]_{\alpha}^{\beta} [T^{-1}]_{\beta}^{\alpha}$

$$\therefore [T]_{\alpha}^{\beta} [T^{-1}]_{\beta}^{\alpha} = I_m.$$

A similar argument gives us that

A similar argument gives us that

$$[T^{-1}]_{\beta}^{\alpha} [T]_{\alpha}^{\beta} = I_n \longrightarrow (*)$$

And therefore $[T]_{\alpha}^{\beta}$ is invertible with inverse

$$([T]_{\alpha}^{\beta})^{-1} = [T^{-1}]_{\beta}^{\alpha} \quad (\text{from } (*)).$$

So, let me just note that down, recall that, $[TT^{-1}]_{\beta}^{\beta}$ is equal to $[T^{-1}]_{\beta}^{\alpha} [T]_{\alpha}^{\beta}$ and $[T]_{\alpha}^{\beta}$ is equal to the identity matrix, identity matrix of size m . A similar argument is noted a similar argument tells us that $[T^{-1}]_{\beta}^{\alpha} [T]_{\alpha}^{\beta}$ is the identity matrix of size n because $T^{-1}T$ will just turn out to be the identity map of the vector space V and this will hence tell us.

And therefore, matrix $[T]_{\alpha}^{\beta}$ is invertible, what is the inverse, with inverse $[T^{-1}]_{\beta}^{\alpha}$ inverse being equal to the inverse of the matrix of the inverse from star, this is from star, alright so, we have proved one half of the theorem which states that if T is an invertible linear transformation, then the matrix associated to T with respect to α, β is invertible,

moreover, if $T_{\alpha\beta}$ is the matrix, the inverse of that matrix will be the matrix of T inverse corresponding to $\beta\alpha$.

(Refer Slide Time: 12:14)

(⇐) Let $[T]_{\alpha}^{\beta}$ be an invertible matrix with inverse given by B

Let $\alpha = (v_1, \dots, v_n)$ and $\beta = (w_1, \dots, w_m)$

Let $B = \begin{pmatrix} b_{11} & \dots & b_{1m} \\ \vdots & & \vdots \\ b_{n1} & \dots & b_{nm} \end{pmatrix}$

So, now let us prove the other direction. So, what is the other direction, the other direction demands that if you start off with an invertible m cross n matrix corresponding to a linear transformation, then the matrix the linear transformation is also an invertible linear transformation. So, let $T_{\alpha\beta}$ be the matrix of T sorry, of course, this is the matrix of T with respect to $\alpha\beta$, let me try that again and again. Let this matrix be an invertible matrix with inverse given by B .

So, let us give some name to vectors, let us list down the vectors in the ordered basis α and β . So, let α be an ordered basis of V , which has dimension n and let v_1, v_2, \dots, v_n correspond to the vectors in the ordered basis α and β similarly, be some w_1 to, recall that W is of dimension m , so, this will be some list of m vectors so let α and β be ordered basis of v and w consisting of v_1 to v_n as the vectors in α and w_1 to w_m as the vectors in β .

And we know that there is an inverse to the given matrix associated to T corresponding to these basis. So, let us see what the entries of this matrix is. So, let B be equal to something like b_{ij} so, where is what is b ? b is the inverse of the matrix associated to T which is going to be an m cross n matrix. So, this is going to be an n cross m matrix. This is going to be $n \times m$.

(Refer Slide Time: 14:43)

Let $B = \begin{pmatrix} b_{11} & \dots & b_{1m} \\ \vdots & & \vdots \\ b_{n1} & \dots & b_{nm} \end{pmatrix}$

Define $S : W \rightarrow V$ in the following manner.

Recall that to define a linear transformation from $W \rightarrow V$ it is enough to describe the fn. S on a basis of W .

Consider $S w_j = b_{1j} v_1 + b_{2j} v_2 + \dots + b_{nj} v_n$

Now, let us define a function. So define function S from W to V in the following manner we will try to use, we will invoke one of the theorems we have proved in one of the previous videos namely which says that if you are given basis of the domain in this case W and say basis consisting of say w_1, w_2, \dots, w_m and suppose you are given vectors say x_1, x_2, \dots, x_n in V , then there exists a unique linear transformation which maps w_i to x_i . So, let us use that to define this particular map S by defining what S is on a basis of W .

So, recall that to define linear transformation on W linear transformation from W to V . It is enough to describe the function S on a basis of W but we are already given a basis of W . So, consider S of w_j , this is how we would like to go about defining our linear map S , but what would $S w_j$ be, when we know that the matrix of S should be B , so that is our goal, so we would like to somehow construct an inverse of T , what is the information we have?

The information we have is the inverse of the matrix corresponding to T and we are already familiar with what the matrix of this inverse should be, it will be the inverse of the matrix. So our expectation should be that the matrix of S should be B corresponding to β . If that is to be the case, let us see what $S w_j$ should be. Let us let me show you what B is on the top. And let me define $S w_j$ by keeping B above, so this will just turn out to be equal to $b_{1j} v_1$ plus $b_{2j} v_2$ plus $b_{nj} v_n$ which let us call it as u_j .

(Refer Slide Time: 18:05)

Then $\exists!$ linear transformation $S: W \rightarrow V$ s.t.

$$S w_j = u_j.$$

Consider

$$\begin{aligned} [TS]_{\beta}^{\beta} &= [T]_{\alpha}^{\beta} [S]_{\beta}^{\alpha} = [T]_{\alpha}^{\beta} B = I_m \\ &= [I_W]_{\beta}^{\beta} \end{aligned}$$

$\Rightarrow TS = I_W$

By one of those theorems which we proved earlier then there exists unique linear transformation S from W to V . So, let us call this u_j such that Sw_j is equal to u_j . My claim now is that this linear transformation S is the inverse of T . So, how do we go about proving that?

So, let us see what the matrix corresponding to TS is. So, consider TS with respect to β α , so, we know that TS is our map linear transformation from W to itself. So this is not β α , this is β β . And we know that this is the composition of 2 linear transformation.

So, this will be S β α to the right and the T α β . And we know that this is equal to T α β times B , which you should go back and check by the very definition of our S here the matrix of S turns out to be B . So, this is equal to T α β times B but what was B , B was exactly the inverse of our matrix, T α β which is just equal to the identity map of size m .

But we know some linear transformation which gives us this particular matrix which is just going to be equal to the identity map from W to itself corresponding to β . So, from here, it is straight forward to check that TS is equal to I_W . So, it is an exercise for you to see that this is equal on each of the basis vectors. Therefore, by the, or rather just straight forward I would not want to call it an exercise but nevertheless you should check this particular arrow carefully.

(Refer Slide Time: 20:30)

$$\text{Wtly } ST = I_V$$

Therefore S is the inverse of T

$\Rightarrow T$ is an invertible linear transformation — \square .

Corollary: Let A be an $m \times n$ matrix.

Corollary: Let A be an $m \times n$ matrix. Then A is invertible if and only if L_A is invertible.

$$\text{Also } L_A^{-1} = L_{A^{-1}}$$

Similarly, you will be able to conclude that ST is equal to I_V and therefore, S is the inverse of T which gives T is an invertible linear transformation that completes our proof. Alright so, now given a matrix A that is a very natural linear transformation which can be associated to it namely L_A . So, this theorem tells us that A is an inverted, so let me write it down as a corollary.

So, let A be and an m cross n matrix then A is invertible if and only if L_A is invertible not just that we know more, we know exactly how or what L_A is. Also L_A inverse the inverse of linear transformation L_A will be the linear transformation corresponding to a inverse. So, the prove is just a direct application it is a corollary, it is a direct application of the previous theorem.

(Refer Slide Time: 22:22)

Also $L_A = L_{A^{-1}}$.

Proof: Let α and β be the standard bases of \mathbb{R}^n and \mathbb{R}^m resp.

$$[L_A]_{\alpha}^{\beta} = A$$
$$\left([L_A]_{\alpha}^{\beta}\right)^{-1} = A^{-1} = [L_A^{-1}]_{\beta}^{\alpha}$$

So, the first part is fairly straight forward. Notice that with respect, so it is just finally boiling down to the choice of the right basis. So, let alpha and beta be the standard bases of \mathbb{R}^n and \mathbb{R}^m respectively and just boils down to taking that with respect to the standard bases the matrix of L_A is just A and the previous theorem tells us that L_A inverse L_A alpha beta the whole inverse the matrix inverse which is equal to A inverse, this is equal to L_A inverse beta alpha by our theorem which we have just proved.

(Refer Slide Time: 23:36)

$$\left([L_A]_{\alpha}^{\beta}\right)^{-1} = A^{-1} = [L_A^{-1}]_{\beta}^{\alpha}$$

But $[L_A^{-1}]_{\beta}^{\alpha} = A^{-1}$

$$\therefore [L_A^{-1}]_{\beta}^{\alpha} = [L_A^{-1}]_{\beta}^{\alpha}$$
$$\Rightarrow L_{A^{-1}} = L_A^{-1} \quad \blacksquare$$

But we also know that A inverse is the matrix of the linear transformation corresponding to A inverse but let me write it down $L_{A^{-1}}$ with respect to say beta alpha is nothing but A inverse. And therefore, $L_{A^{-1}}$ beta alpha is equal to the matrix of the inverse of the

linear transformation LA with respect to β and α and from there again, on the basis it is equal and therefore, it will be equal everywhere. And that establishes the corollary.

(Refer Slide Time: 24:24)

Corollary: Let A be an invertible $m \times n$ matrix. Then
 $m = n$.

Proof: A is an invertible matrix \Leftrightarrow
 $L_A: \mathbb{R}^n \rightarrow \mathbb{R}^m$ is an invertible linear transformation
 $\Rightarrow \dim(\mathbb{R}^n) = \dim(\mathbb{R}^m)$
 $\Leftrightarrow n = m$.

Another corollary is that so let me just note it down another corollary states that if A is an m cross n , it is a corollary to this corollary which states that if A is invertible m cross n matrix and m is necessarily equal to n . So, let us see how that is. So, let A be an invertible m cross n matrix then m is equal to n . So, by the previous theorem. So, let us look at a proof, by the previous theorem A is invertible matrix if and only if LA , so, where is LA from? LA is a map from \mathbb{R}^n to \mathbb{R}^m . So, LA is an invertible linear transformation.

Now, what do we know about isomorphic vector spaces so, we know that two vector spaces are isomorphic or in other words there exist an invertible linear transformation between them, if and only if their dimensions are the same. So, which we have proved in one of the videos in this week, this is if and only if the dimension of \mathbb{R}^n which is equal to n .

So, dimension of \mathbb{R}^n is equal to the dimension of \mathbb{R}^m but what is dimension of \mathbb{R}^n that is n and what is dimension of \mathbb{R}^m that is m and therefore, this is a if and only if n is equal to m . So, A is an invertible linear transformation. So, there is a slight error which one should be very careful about so this will tell us that dimension of \mathbb{R}^n is equal to dimension of \mathbb{R}^m .

It is not an if and only if statement. You could have LA which is not necessarily an invertible linear transformation, even though the domain and the range are \mathbb{R}^n . So, for example, look at the map LA corresponding to the 0 matrix that will not be an invertible transformation. So, this direction of the implication here which I am now circling in green one should be very

careful I had written and if and only if there which is not the case. So, this implies that dimension of R^n is equal to dimensional R^m , which is if and only if and n is equal to m .

So, we have effectively shown that if A is invertible m cross n matrix then n is necessarily equal to m . Alright so, in the proof of the theorem which we proved just now, the theorem which stated that if T or rather T is an invertible linear transformation if and only if the matrix associated to T is invertible.

We used an argument to construct a specific inverse linear transformation of T , we shall use that style of construction to prove that the vector space of all linear transformations between v and w which we had seen earlier and we had given a name L of V , comma W that is isomorphic to all m cross n matrices over R , so, that is the next theorem that we will be proving.

(Refer Slide Time: 28:38)

Recall that $L(V, w)$ denoted the vector space
of all linear transformations from V to W .

Theorem: Let V and W be finite dimensional vector spaces. Let $\dim(V) = n$ and $\dim(W) = m$. Then $\mathcal{L}(V, W)$ is isomorphic to $M_{m \times n}(\mathbb{R})$.

Proof: Let $\alpha = (v_1, \dots, v_n)$ and $\beta = (w_1, \dots, w_m)$

be bases of V and W respectively.

So, recall that $\mathcal{L}(V, W)$ denoted the vector space of all linear transformations from V to W . So, this theorem tells us that $\mathcal{L}(V, W)$ is isomorphic to the matrices of size m cross n when V and W are respectively of dimension m and n . So, let us see what the statement is. So, let V and W be finite dimensional vector spaces.

Suppose, the dimension of V is equal to n and the dimension of W is equal to m . So, let the dimension of V is equal to n and dimension of W be equal to m , then the theorem states that $\mathcal{L}(V, W)$ is isomorphic to the matrices of \mathbb{R} of size m cross n , let us give a proof of this, the proof is quite straightforward.

We have seen the idea that is being used in this proof, just a few minutes back, so it is just going to be a imitation of that. So, let us start by fixing an ordered basis. So, let α be equal to, v_1 to v_n and β equal to w_1 to w_m be bases of V and W respectively.

(Refer Slide Time: 31:07)

be bases of V and W respectively.

Define

$$\Phi: \mathcal{L}(V, W) \rightarrow M_{m \times n}(\mathbb{R})$$
$$\Phi(T) = [T]_{\alpha}^{\beta}$$
$$\Phi(T) = [T]_{\alpha}^{\beta}$$
$$\Phi(S+T) = [S+T]_{\alpha}^{\beta} = [S]_{\alpha}^{\beta} + [T]_{\alpha}^{\beta}$$
$$= \Phi(S) + \Phi(T) \quad \forall S, T \in \mathcal{L}(V, W)$$
$$\Phi(cT) = c \Phi(T) \quad \forall T \in \mathcal{L}(V, W) \text{ and } c \in \mathbb{R}.$$

Let us now define a map Φ so define capital Φ from $\mathcal{L}(V, W)$ into the m cross n matrices over \mathbb{R} . So, recall that m cross n matrices over \mathbb{R} was a vector space consisting of all m cross n matrices and it was having a basis with all the matrices with 1 say e_{ij} and 0 elsewhere so there will be mn of them.

So, the dimension of the vector space on the right is actually mn . So let us define a map Φ from $\mathcal{L}(V, W)$ into m cross n over \mathbb{R} by what you should be expecting. Φ of a linear transformation T is just going to be the matrix of T responding to α and β .

So, we have seen that Φ is linear transformation in another guys, we have already seen it, let us check that Φ is linear transformation, so to see that $\Phi(S+T)$ is going to be equal to

the matrix of S plus T alpha beta. And we have already seen that this is equal to S alpha beta plus T alpha beta, which is equal to ϕ of S plus ϕ of T .

And similarly, the scalar multiple, so, this is for all S and T in L of v, w and similarly, ϕ of c times T is nothing but c times ϕ of T for all T in L of v, w and C in the scalars. So, what is ϕ of cT it is going to be the matrix of cT with respect to alpha and beta which is going to be c time the matrix of T with respect to alpha and beta, which is nothing but c times $V T$.

So, you have seen these two in the first video of this week. So, we have what we have done just now is to establish that our map ϕ which we just defined is a linear transformation from L of v, w into the m cross n matrices over R . So, what remains to show is that it is an isomorphism.

So, invoking another result, which we have already shown, we will prove that ϕ is both injective and surjective. And thereby proving that an injective and surjective linear transformation is an invertible linear transformation, you use that research to prove that ϕ is then an invertible linear transformation.

(Refer Slide Time: 34:15)

$$\underline{\phi}(cT) = c \underline{\phi}(T) \quad \forall T \in L(v, w) \text{ \& } c \in R.$$

Exercise: $\text{Null}(\underline{\phi}) = 0 \leftarrow \text{zero linear transformation}$
 $\Rightarrow \underline{\phi}$ is injective.

Surjectivity: Let A be an $m \times n$ matrix

vector spaces. Let $\dim(V) = n$ and $\dim(W) = m$. Then $\mathcal{L}(V, W)$ is isomorphic to $M_{m \times n}(\mathbb{R})$.

Proof: Let $\alpha = (v_1, \dots, v_n)$ and $\beta = (w_1, \dots, w_m)$

be bases of V and W respectively.

Define

$$\Phi: \mathcal{L}(V, W) \rightarrow M_{m \times n}(\mathbb{R})$$

$$\Phi(T) = [T]_{\alpha}^{\beta}$$

$$\Phi(c \cdot T) = [c \cdot T]_{\alpha}^{\beta} = c [T]_{\alpha}^{\beta} = c \Phi(T)$$

$$A = \begin{pmatrix} a_{11} & \dots & a_{1n} \\ \vdots & & \vdots \\ a_{m1} & \dots & a_{mn} \end{pmatrix}$$

Define $T: V \rightarrow W$ where

$$T v_j = a_{1j} w_1 + a_{2j} w_2 + \dots + a_{mj} w_m.$$

Check that $[T]_{\alpha}^{\beta}$.

So, the injectivity comes by noting that so this I will leave it as an exercise for you to check that the null space of phi is necessarily the 0 linear transformation is the 0. So, this is the 0 linear transformation. Just notice what the matrix corresponding to phi will turn out to be if the linear transformation is being mapped to the 0 vector, 0 matrix. It will just be the matrix with 0 entries. Which means that every bases vector is being send to the 0 vector and therefore, the linear transformation is the 0 linear transformation.

So, this particular exercise establishes that phi is injective. Notice that we have already shown that phi is a linear transformation and this tells us that phi is injected and how about surjectivity. So, let surjectivity that is non- exclusive. So, let us take some arbitrary m cross n matrix so let A be an m cross n matrix. We have seen this technique, this is what I was

talking about a few minutes back. So, let A be the matrix given by these entries and did we give what the vectors? Yes.

So, v_1 to v_n and w_1 to w_m are the vectors in the ordered basis corresponding to α and β . So, define, let us define a map T , V to W , where Tv_j will just turn out to be equal to $a_{1j}w_1$ plus $a_{2j}w_2$ plus $a_{mj}w_m$. So, check that the matrix of T corresponding to α β , sorry.

(Refer Slide Time: 36:58)

$$Tv_j = (a_{1j}w_1 + a_{2j}w_2 + \dots + a_{mj}w_m)$$

∃! linear transformation $T: V \rightarrow W$ s.t.

$$Tv_j = (a_{1j}w_1 + \dots + a_{mj}w_m).$$

Check that $[T]_{\alpha}^{\beta} = A.$
 i.e. $\Phi(T) = A.$

Thus Φ is an isomorphism.

Before that I just defined what T is on the basis vectors α . And by 1 of the theorems you have proved earlier that it is a unique linear transformation, which maps each of the v_j to the vector which I just put in the bracket. It is called Tv_j where it is a unique linear transformation there exists a unique linear transformation by one of the theorems proved earlier linear transformation T which maps, so what is that?

Here I have only defined T for the basis elements, v_1 v_2 up to v_m and with that there exists a unique linear transformation T from V to W such that T of v_j is equal to $a_{1j}w_1$ plus $a_{mj}w_m$ and what is the matrix of T with respect to α β , check that this is equal to A . But what does it mean to say that the matrix of T with respect to α β is A , it means that i.e. ϕ of T is equal to A , that shows that our map ϕ is surjective. So, we have shown both injectivity and surjectivity. Thus, ϕ is an isomorphism.

(Refer Slide Time: 38:49)

Recall that $L(V, W)$ denoted the vector space of all linear transformations from V to W .

Theorem: Let V and W be finite dimensional vector spaces. Let $\dim(V) = n$ and $\dim(W) = m$. Then $L(V, W)$ is isomorphic to $M_{m \times n}(\mathbb{R})$.

Proof: Let $\alpha = (v_1, \dots, v_n)$ and $\beta = (w_1, \dots, w_m)$

be bases of V and W respectively.

Check that $[T]_{\beta}^{\alpha} = A$.

i.e. $\Phi(T) = A$.

Thus Φ is an isomorphism. \square

Corollary: $\dim(L(V, W)) = mn$.

So, what we have essentially shown it is a very powerful result. Let me just show you the result once more. This theorem tells us that the vector space of all linear transformations from V to W is isomorphic to the m cross n matrices over \mathbb{R} . And as a corollary, so, let us stop with the corollary which is a direct consequence of the theorem, it tells us what the dimension of L of v, w is.

Dimension of L of v, w remember that two matrices are isomorphic if and only if their dimensions are the same, so this is nothing but dimension of the m cross n matrices over \mathbb{R} which is equal to m times n , so this has already proved the result corollary states that the dimension of L of v, w is (mn) (39:33). Let me stop here.
