Change of Basis

So, in the last week we discussed how given a vector space v and an ordered basis of v we could associate column corresponding to every vector. We also saw that if v and w are two vector spaces and if we fixed two basis of v and w respectively, then every linear transformation can be associate to a matrix. So, we begin this week by discussing how this association depends on the basis in other words we would like how the column changes, the column representation changes when we change the ordered basis with respect to which we are looking at it or how the matrix of the transformation changes when we change this basis.

(Refer Slide Time: 0:58)

So, let us begin by considering a vector space v so, let v be a finite dimensional vector space and let β be an ordered basis, β be an ordered basis of v . Let us, now consider a new basis β' , let β' be another ordered basis. So, let us ask the right question given a vector v in capital V we would like to see how are the column representations of v with respect to β which we already denoted by $[v]^\beta$ is related to the column representation of v with respect to β' this is what we would like to first explore.

So, in order to study the relationship between $[v]^\beta$ and $[v]^{\beta'}$ what we will do is we will consider the most natural linear transformation we can think of which is the identity linear transformation.

(Refer Slide Time: 3:01)

basis. Given $v \in V$, now we are looking representation of v w.r.t β , denoted by $[v]^\beta$ is related to $[v]^{\beta'}$?

To study this, consider $I_V : V \rightarrow V$ the identity linear transformation.

\uparrow ordered basis β \uparrow ordered basis β'

So, to study the above, to study this consider I_V which is from V to itself the identity linear transformation, identity linear transformation. So, what we will do is we will consider the domain V with the basis β , so here, let us consider V with ordered basis β and this one is the ordered basis β' , it is considered with the ordered basis β' .

So, remember v and w we have to fix a basis for V , we have to fix a basis for W and then we would like to locate the matrix corresponding to these two basis and that precisely what we will do here, we would like to see how the matrix of identity with respect to β and β' look like.

(Refer Slide Time: 4:17)

of v w.r.t β , denoted by $[v]^\beta$ is related to $[v]^{\beta'}$?

To study this, consider $I_V : V \rightarrow V$ the identity linear transformation.

\uparrow ordered basis β \uparrow ordered basis β'

Consider the matrix $[I_V]_{\beta}^{\beta'}$.

We know that $I_V v = v$

Consider the matrix $[I_V]_{\beta}$.

We know that $I_V v = v$

$$\text{Then } [I_V v]_{\beta'} = [I_V]_{\beta'} [v]_{\beta}.$$

$$\Rightarrow [v]_{\beta'} = [I_V]_{\beta'} [v]_{\beta}.$$

The matrix $[I_V]_{\beta'}$ is called

The matrix $[I_V]_{\beta'}$ is called the change of basis matrix from β to β' .

Proposition: $[I_V]_{\beta'}$ is invertible.

Proof: The matrix corresponding

Proof: The matrix corresponding to an invertible linear transformation is invertible. I_V is an inv. lin. trans.

Thus $[I_V]_{\beta'}$ is hence an invertible.

* If $\dim V = n$, then $[I_V]_{\beta'}$ is an $n \times n$ matrix

So, consider the matrix I_V with respect to β and β' . So, let me just give the definition for it or maybe I will just tell you how this matrix is important and then let me give you the name of this matrix. So, we know that I_V of v is equal to v after all I_V is the identity transformation but, think of I_V as a linear transformation from V to itself in the above set up, where the domain V is with the basis β and the co-domain or the target V is with the basis β' .

Then, whatever the theory we have developed in the last week tells us that I_V of v with respect to β' , remember this is in the co-domain, this is in the range this is equal to $I_V \beta, \beta' \times v \beta, I_V$ is after all a linear transformation but, what is I_V of w ? This gives $v \beta'$ is equal to $I_V \beta, \beta' \times v \beta$.

We have found out explicitly what the relationship between $v \beta$ and $v \beta'$, it is related by the matrix multiplication of the matrix I_V with respect to β and β' this matrix, the matrix $I_V \beta, \beta'$ is called the change of basis matrix, the change of basis matrix from β to β' .

So, immediately let me give you an proposition $I_V \beta, \beta'$ is invertible it is an invertible matrix, why is this invertible? we have already seen that if we have a linear transformation which is invertible the matrix corresponding to the linear transformation should also be necessarily be invertible and we know that identity is a invertible linear transformation it is the inverse of itself.

So, the matrix the reason is that matrix corresponding to invertible linear transformation with respect to any basis is invertible you fix any two basis and if you look at the matrix of invertible linear transformation, we have proved that it is invertible and identity is an invertible linear transformation and thus I_V from β to β' is hence an invertible matrix, what else can we observe?

Observe at $I_V \beta, \beta'$ is an n cross n matrix where, n is the dimension of V if dimension of V is equal to n and, then $I_V \beta, \beta'$ is an n cross n matrix, we should be able to say more, I leave it as an exercise for you to check may be I will just do it, I will leave it as an exercise for you to check that the change of basis matrix from β' to β is exactly v inverse of the change of basis matrix from β to β' .

(Refer Slide Time: 9:31)

* If $\dim V = n$, then $[\mathcal{I}_V]_{\beta}^{\beta'}$ is an $n \times n$ matrix

* Exercise: Prove that the change of basis matrix $[\mathcal{I}_V]_{\beta}^{\beta'}$ is the inverse of the change of basis matrix $[\mathcal{I}_V]_{\beta'}^{\beta}$ from β' to β .

Example: Let us consider $V = \mathbb{R}^2$ with $\beta = (e_1, e_2)$, the standard basis and $\beta' = (1, 1), (1, -1)$.

$$e_1 = \mathcal{I}_V e_1 = (1, 0) = \frac{1}{2}(1, 1) + \frac{1}{2}(1, -1).$$

$$e_2 = \mathcal{I}_V e_2 = (0, 1) = \frac{1}{2}(1, 1) + \left(-\frac{1}{2}\right)(1, -1)$$

$$\Rightarrow [\mathcal{I}_V]_{\beta}^{\beta'} = \begin{pmatrix} \frac{1}{2} & \frac{1}{2} \\ \frac{1}{2} & -\frac{1}{2} \end{pmatrix}.$$

$$\text{Let } v = (x, y) \in \mathbb{R}^2 \quad \text{then} \quad [v]_{\beta} = \begin{pmatrix} x \\ y \end{pmatrix}$$

$$\text{note that } v = (x, y) = \frac{(x+y)}{2}(1, 1) + \frac{(x-y)}{2}(1, -1).$$

$$[v]_{\beta'} = \begin{pmatrix} (x+y)/2 \\ (x-y)/2 \end{pmatrix}$$

Moments thought should be view that the change of basis matrix I_V from β to β' is the inverse of the change of basis matrix I_V from β' to β . So, we have explored how the change of basis matrix gives us the relationship between the column vector representation of a vector with respect to β and the column representation of a vector with respect to β' .

Let us look at an example, so an example let us consider the simplest example, may not the simplest but a simple example, let us consider V to be just \mathbb{R}^2 with β the standard basis e_1 which is $(1, 0)$ and e_2 which is $(0, 1)$ the standard basis and β' be the vectors may be $(1, 1)$ and $(1, -1)$. Let us try to see what the change of basis matrix is. The change of basis matrix is calculated by evaluating what the identity matrix is or at e_1 and at e_2 , they will give the columns with respect to $(1, 1)$ and $(1, -1)$.

So, observe that e_1 which is equal to I_V of e_1 is equal to $(1, 0)$ which is equal to half of $(1, 1)$ plus half of $(1, -1)$. So, the first column will just turn out to be half and half e_2 on the other hand which is equal to I_V of e_2 which is $(0, 1)$ this is equal to half of $(1, 1)$ plus minus half of $(1, -1)$. So, these two calculations tell us that I_V of β of V of identity with respect to β and β' is nothing but $\frac{1}{2}$ by $\frac{1}{2}$, $\frac{1}{2}$ by $\frac{1}{2}$, $\frac{1}{2}$ by $\frac{1}{2}$, minus $\frac{1}{2}$ by $\frac{1}{2}$ that is good.

So, let us now see given an arbitrary vector, let us see by brute force how I_V β is and what v β' is and also let us see whether they are related in the manner we have just seen, so of course be the same not able look at it in brute force. So, let x, y be some vector in say \mathbb{R}^2 this is clearly equal to then there is no confusion on what v β is, then v β by very definition is x, y this is after all x times e_1 plus y times e_2 .

So, note that v which is equal to x, y this is equal to x plus y by $\frac{1}{2}$ times $(1, 1)$ plus x minus y by $\frac{1}{2}$ times $(1, -1)$ this is what our x, y is with respect to $(1, 1)$. So, v β' is x plus y by $\frac{1}{2}$ x minus y by $\frac{1}{2}$. So, if v is $(2, 3)$ v β will be $(2, 3)$ here and if v is $(2, 3)$ then v β' will be $(\frac{5}{2}, \frac{1}{2})$.

(Refer Slide Time: 15:24)

$$[I_V]_{\beta'}^{\beta} [v]_{\beta} = \begin{pmatrix} 1/2 & 1/2 \\ 1/2 & -1/2 \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} (x+y)/2 \\ (x-y)/2 \end{pmatrix} = [v]_{\beta'}$$

Let $T: V \rightarrow V$ be a linear transformation. A linear transformation V to itself is called a linear operator.

Let β and β'

Let $T: V \rightarrow V$ be a linear transformation. A linear transformation V to itself is called a linear operator.

Let β and β' be ordered basis of V .

Then if you observe what is $[I_V]_{\beta'}^{\beta}$, β' times v β this is nothing but recall what $[I_V]_{\beta'}^{\beta}$ is half, half, half, minus half this is going to be half, half, half, minus half, and what was our v β ? v β was x, y this is equal to you do the calculations this will turn out to be x plus y by 2 and x minus y by 2 which precisely is our v β' and that is precisely what we have just shown.

So, this is exactly how the change of basis matrix comes into the picture when we would like to look at how the column vector of v with respect to β is related to the column vector of v with respect to the β' basis β' . Now, let us consider how the matrix of a linear transformation changes when we change the basis of the given vector space so, for simplicity let us do the study for linear transformations from V to itself.

So, change of basis matrix and the linear transformations so, not to do that let T, not to study that consider a vector space linear transformation from the vector space v to itself be a linear transformation, such a linear transformations are called linear operator as well so, I will just note that as well linear transformation. A linear transformation v to itself is called linear operator.

So, let us look at how the matrix of a linear operator changes when we change the basis ordered basis with respect to which we are looking at the matrix. So, again let us fix a basis let beta and another basis let beta and beta prime be ordered basis of v. So, consider two different ordered basis of v, then we have a matrix of T with respect to beta and beta and there is also a matrix of T with respect to beta prime and itself.

(Refer Slide Time: 18:39)

Let us study how $[T]_{\beta}^{\beta}$ and $[T]_{\beta'}^{\beta'}$ are related.

$$\begin{array}{c}
 V \xrightarrow{I_V} V \xrightarrow{T} V \xrightarrow{I_V} V \\
 \beta' \quad \quad \beta \quad \quad \beta'
 \end{array}$$

$$I_V T I_V = T$$

$$[T]_{\beta'}^{\beta'} = [I_V T I_V]_{\beta'}^{\beta'} = [I_V]_{\beta'}^{\beta'} [T]_{\beta}^{\beta} [I]_{\beta}^{\beta'}$$

Let $Q = [I_V]_{\beta'}^{\beta}$

Then $[T]_{\beta'}^{\beta'} = Q [T]_{\beta}^{\beta} Q^{-1}$

Two matrices A and B are said to be similar if there exists an invertible matrix Q s.t

$$A = QBQ^{-1}$$

So, consider so let us study how T_{β} , β and $T_{\beta'}$, β' are related. So, the idea is almost the same but we will do is we will consider the following. So, let us consider T is a map from V to itself again this is with respect to the basis, say β and this is with respect to the basis β' that is what will give you T_{β} , β and then let us consider the matrix to be the linear transformation identity, however the range let us consider with respect to β' and here again let us consider the identity matrix here with respect to β' .

So, what this chain tells us is that $I_{\beta'} T I_{\beta}$ is equal to identity composed with T composed with identity it is nothing but our T . So, this map that is also T but, we have developed some notion of how the matrix corresponding to linear transformations behave when we consider compositions, they will just turn out to be the product.

So, let us write that down so, this $I_{\beta'} T I_{\beta}$ with respect to β' , β' this by what we have seen earlier is nothing but I_{β} from β to β' here from here times T β to β from here and the times $I_{\beta'}$ from β' to β but this left hand side is nothing but T because $I_{\beta'} T I_{\beta}$ is just T and this is with respect to β' and β .

So, let Q be the matrix I_{β} from β to β' , then $T_{\beta'}$, β' is equal to $Q T_{\beta}$, β Q^{-1} we have already checked but at least it was given as an exercise that the change of basis matrix from β to β' is the inverse of the change of basis matrix from β' to β and of that matrix is Q , then the matrix of T with respect to β' , β' is equal to Q times T matrix with respect to β and β times Q^{-1} .

So, that is precisely how the matrix of a linear operator or a linear transformation from V to itself behaves when we change the basis from β to β' , such a relationship is given a name it is called similar, similarity two matrices A and B are said to be similar if there exists an invertible matrix Q , such that A is equal to $Q B Q^{-1}$. We will see later that such matrices, similar matrices share a lot of common properties therefore, this particular relation that we have just explore is of extreme importance when we study linear algebra further.

So, we will see more examples of how linear transformations are the matrix of linear transformations are related to each other through further concrete examples and problems in the problem section.
