

**Linear Algebra**  
**Professor Pranav Haridas**  
**Kerala School of Mathematics, Kozhikode**  
**Lecture 5.2**  
**Product of Vector Spaces**

So, given two sets  $x$  and  $y$  we are familiar with the notion of the Cartesian product of  $x$  and  $y$ . It is the collection of all tuples  $x, y$  where  $x$  is in capital  $X$  and  $y$  is in capital  $Y$ . So, we would like to ask this question, if we start off with vector spaces  $v$  and  $w$  instead of arbitrary sets, we can still take the Cartesian product of  $V$  and  $W$ , can we associate a vector space structure to  $V \times W$  which directly or which is dependent on the vector space structure of  $V$  and the vector space structure of  $W$  respectively.

(Refer Slide Time: 1:02)

Let  $V_1, V_2, \dots, V_n$  be vector spaces over  $\mathbb{R}$ . Consider the product of  $V_1, \dots, V_n$

$$V_1 \times V_2 \times \dots \times V_n := \{ (v_1, v_2, \dots, v_n) : v_i \in V_i \}$$

Vector addition:

So, let us begin by associating some such thing so, do that let us begin by considering vector spaces  $V_1, V_2, \dots, V_n$ . Let  $V_1, V_2, \dots, V_n$  be vector spaces over  $\mathbb{R}$  all of these are vector spaces over  $\mathbb{R}$ , we are not demanding any extra restrictions on these  $V_1, V_2, \dots, V_n$  could be any vector space. Consider, the Cartesian product of  $V_1$  to  $V_n$  it is just the product of sets as of now given by  $V_1 \times V_2 \times \dots \times V_n$  which by definition is the set of all in tuples  $V_1, V_2, \dots, V_n$  where  $v_i$  belongs to capital  $V_i$ .

So, the  $i$ th component in this tuple is a vector from  $V_i$ . So, we would like to ask, we would like to ask whether we can associate addition and scalar multiplication to this Cartesian product and give it a vector space structure. So, we know that each of these  $V_i$ 's are the vector spaces and that there is a scalar multiplication, there is an addition operation, there is a

scalar multiplication in each of these  $V_i$ 's. We are going to use that information to get hold of new operation on  $V_1$  cross up to  $V_n$  and give it a vector space structure.

(Refer Slide Time: 3:26)

Vector addition:

Let  $(v_1, v_2, \dots, v_n)$  and  $(v'_1, v'_2, \dots, v'_n) \in V_1 \times V_2 \times \dots \times V_n$ .

$$(v_1, v_2, \dots, v_n) \oplus (v'_1, v'_2, \dots, v'_n) := (v_1 \oplus v'_1, v_2 \oplus v'_2, \dots, v_n \oplus v'_n).$$

---

So, let us try to define the addition, vector addition. So, let us take two arbitrary vectors so, let  $V_1, V_2, \dots, V_n$  and  $V_1 \text{ prime}, V_2 \text{ prime}, \dots, V_n \text{ prime}$  be two different vectors, be vectors or elements in as of now there are no vectors, because we have not given any vector space structure to it. So, be two elements so, let me just use the shorthand notation be elements of  $V_1$  cross  $V_2$  cross  $V_n$  our goal is to somehow give an addition operation on  $V_1$  cross  $V_2$  cross up to cross  $V_n$ .

So, not up to do that we should be able to say what is these vector sum of this vector  $V_1$  to  $V_n$  and the vector  $V_1 \text{ prime}$  to  $V_n \text{ prime}$ . The addition operation is the natural addition operation that comes to our mind initially which is namely this plus this  $V_1 \text{ prime}$  to  $V_n \text{ prime}$ , this is being defined that to be  $V_1$  plus  $V_1 \text{ prime}$ , component wise  $V_2$  plus  $V_2 \text{ prime}$ , up to  $V_n$  plus  $V_n \text{ prime}$ . So, I would like to draw your attention to a few things.

So, let me use some colors the green which is being circled is the operation which we are defining, the blue circle is the operation which we know from capital  $V_1$ , the red is the operation in capital  $V_2$ , the yellow is the operation in capital  $V_n$ . So, as you can see we are using the same plus notation everywhere the use of notation is a quite evident however, the situation is clarifying which operation is being used where the fact that this operation, this yellow one which I will just underlined is the operation that is being defined is quite clear from the context and we will be making use of this clarity in order to define such things.

Alright so, we have defined  $V_1, V_2, \dots, V_n$  plus  $V_1$  prime,  $V_2$  prime, up to,  $V_n$  prime to be component wise.

(Refer Slide Time: 6:16)

Scalar multiplication:

Let  $c \in \mathbb{R}$  and  $(v_1, v_2, \dots, v_n) \in V_1 \times V_2 \times \dots \times V_n$ .

Define  $c(v_1, v_2, \dots, v_n) := (cv_1, cv_2, \dots, cv_n)$

With these operations,  $V_1 \times V_2 \times \dots \times V_n$  is a vector space (Exercise).

Similarly, we will define scalar multiplication also component wise, scalar multiplication, scalar multiplication needless to say these are closed operations both but, it is something which we should certainly check  $V_1$  plus  $V_1$  prime is going to be an element of  $V_1$  again because,  $V_1$  is closed in vector addition and similarly for all components.

So, now let us define scalar multiplication again this is an operation which will take a scalar, let  $c$  be an element in  $\mathbb{R}$  and  $V_1, V_2, \dots, V_n$  be an element in we would like to define  $c$  times  $V_1, V_2$  up to  $V_n$  define  $c$  times  $V_1, V_2$  up to  $V_n$  to be this is by definition equal to or rather we are defining this to be equal to  $cV_1, cV_2, \dots, cV_n$  again I would like to draw your attention to the various operations that are involved in this, the operation here is the operation we are defining the operation here, here and here are operations which we already know respectively in  $V_1$ , the scalar multiplication in  $V_2$ , and the scalar multiplication in  $V_n$ .

So, we are using that to define the new operation on  $V_1$  cross  $V_2$  cross  $V_3, \dots, V_n$  and we have defined the scalar multiplication and again a similar argument as above tells us that this operation is closed or to put it no, let me make it precise  $V_1$  cross  $V_2$  up to,  $V_n$  is closed under the scalar multiplication which we have just defined with these operations  $V_1$  cross  $V_2$  cross up to  $V_n$  is a vector space.

So, I will leave that as an exercise for you to check the various properties of the vector space the definition of a vector space and convince yourself that this a vector space at this stage I

will leave this as an exercise, this is an exercise however you should certainly sit and work this exercise out to convince yourself that this a way.. There are two things however which I would like to draw your attention to, what will be the identity, additive identity of this vector space? The additive identity of  $V_1 \times V_2 \times \dots \times V_n$  should be  $n$  tuple  $(0, 0, \dots, 0)$  where each of the zeroes are the identity in the corresponding vector space.

(Refer Slide Time: 9:20)

With these operations,  $V_1 \times V_2 \times \dots \times V_n$  is a vector space (Exercise).  
The identity vector in  $V_1 \times V_2 \times \dots \times V_n$  is  
 $(0, 0, \dots, 0)$   
↑     ↑     ↑  
identity of  $V_1$      identity of  $V_2$      identity of  $V_n$ .

So, the identity operation not identity operation, identity vector the additive identity vector this additive identity that we are discussing in  $V_1 \times V_2 \times \dots \times V_n$  is  $(0, 0, \dots, 0)$  I would like to stress upon the fact that this is the additive identity of  $V_1$ , this is of  $V_2$  and this is additive identity of  $V_n$  you should check that certainly this works. Similarly, one more thing I would like to draw your attention to is the inverse.

(Refer Slide Time: 10:22)

identity of  $V_1, V_2, \dots, V_n$ .

Given  $(v_1, \dots, v_n) \in V_1 \times \dots \times V_n$ , the element  $(-v_1, -v_2, \dots, -v_n)$  is the additive inverse of  $(v_1, \dots, v_n)$ .

Examples: Consider  $\mathbb{R}^2 \times \mathbb{R}^3$ .

$\mathbb{R}^2 \times \mathbb{R}^3 = \{(x_1, x_2), (x_3, x_4, x_5) : x_1, x_2, x_3, x_4, x_5 \in \mathbb{R}\}$ .

So, given say  $v_1$  to  $v_n$  in capital  $V_1$  cross up to capital  $V_n$ , recall that there exists an additive inverse of  $V_1, V_2$ , up to  $V_n$  if it all it has to be a vector space, my claim is that the vector of the element this is all be vector only once it is a vector space, so as of now we are still in the process of establishing that this is a vector space even though I have left it as an exercise. The element minus  $V_1$  minus  $V_2$  up to minus  $V_n$  is the additive inverse of  $V_1$  to  $V_n$ , note that minus of  $v_1$  is the additive inverse of  $v_1$  in capital  $V_1$  similarly, minus  $v_2$  is the additive inverse of  $v_2$  in capital  $V_2$ .

So, as you can see we are using the vector space operations in  $V_1, V_2$  up to  $V_n$  respectively, extensively to talk about the vector space structure on  $V_1$  cross  $V_2$  up to  $V_n$ . Alright so, let us look at may be a couple of examples, well consider  $\mathbb{R}^2$  cross  $\mathbb{R}^3$  first two examples that came to my mind. So, let  $V_1$  we have to and  $V_2$  to be  $\mathbb{R}^3$ , let us just consider product of two vector spaces.

So, by what we have just described, what will be this set  $\mathbb{R}^2$  cross  $\mathbb{R}^3$  will just be equal to the set of all  $x_1, x_2$  and then  $x_3, x_4, x_5$  this is an typical element in the tuple of such elements where  $x_1, x_2$  belongs to  $\mathbb{R}^2$  which is same as demanding that  $x_1, x_2, x_3, x_4$  and  $x_5$  are all in  $\mathbb{R}$ .

One will be tempted to tell that  $\mathbb{R}^2$  cross  $\mathbb{R}^3$  which we have just defined is nothing but  $\mathbb{R}^5$  but that is not technically correct  $\mathbb{R}^2$  cross  $\mathbb{R}^3$  can certainly be identified with  $\mathbb{R}^5$  by or through the notion of an isomorphism which we have defined, but it is incorrect to say that  $\mathbb{R}^2$  cross  $\mathbb{R}^3$  is equal to  $\mathbb{R}^5$ , this is after all a tuple of vectors in  $\mathbb{R}^2$  and vectors in  $\mathbb{R}^3$ , it is not the same as giving a vector in  $\mathbb{R}^5$  we will make that precise.

(Refer Slide Time: 13:29)

$$\mathbb{K} \times \mathbb{K} = \{(x_1, x_2), (x_3, x_4, x_5) : x_1, x_2, x_3, x_4, x_5 \in \mathbb{K}\}.$$

Define  $T: \mathbb{R}^2 \times \mathbb{R}^3 \rightarrow \mathbb{R}^5$

$$T((x_1, x_2), (x_3, x_4, x_5)) := (x_1, x_2, x_3, x_4, x_5).$$

Check that  $T$  is an isomorphism.

$$\text{Let } \beta = \left\{ \begin{array}{l} ((1, 0), (0, 0, 0)), ((0, 1), (0, 0, 0)), (0, 0), (1, 0, 0), (0, 0), (0, 1, 0), \\ (0, 0), (0, 0, 1) \end{array} \right\}$$

$$\text{Let } \beta = \left\{ \begin{array}{l} ((1, 0), (0, 0, 0)), ((0, 1), (0, 0, 0)), ((0, 0), (1, 0, 0)), ((0, 0), (0, 1, 0)), \\ (0, 0), (0, 0, 1) \end{array} \right\}$$

Then  $\beta$  is a basis of  $\mathbb{R}^2 \times \mathbb{R}^3$ .

\* Consider the vector space  $\mathbb{P}_2(\mathbb{R}) \times \mathbb{R}^2$

An element will be  $(x^2 + 2, (2, 3))$

Exercise: Check that  $\{(1, (0, 0)), (x, (0, 0)), (x^2, (0, 0)), (0, (1, 0)), (0, (0, 1))\}$  is a basis of  $\mathbb{P}_2(\mathbb{R}) \times \mathbb{R}^2$ .

Define  $T$  from  $\mathbb{R}^2 \times \mathbb{R}^3$  to  $\mathbb{R}^5$  the first natural map that comes to our head which is  $T$  of  $x_1, x_2$  and  $x_3, x_4, x_5$  to be equal to, this is defined to be  $x_1, x_2, x_3, x_4$  and  $x_5$  define  $T$  to be this particular map from  $\mathbb{R}^2 \times \mathbb{R}^3$  into  $\mathbb{R}^5$ , it is very easily checked that  $T$  is a linear transformation and that it is both injective and surjective therefore, it is an isomorphism.

So, I will just leave that as an exercise, check that  $T$  is an isomorphism. So, as already notated an isomorphism is something which essentially helps us in identifying to different vector spaces. So, in particular one of the results from the previous week tells us that the dimension should be the same and that is to be expected and suppose, so if  $e_1, e_2$  is the standard basis or may be let us write down explicitly what the basis here will be so, the first one will be  $1, 0, 0, 0, 0$  then  $0, 1, 0, 0, 0$  and then  $0, 0, 1, 0, 0, 0, 0, 0, 1, 0, 0, 0, 0, 0, 1$  this is essentially obtain

by pulling back the basis from  $\mathbb{R}^5$  to  $\mathbb{R}^2 \times \mathbb{R}^3$  through the linear transformation  $T$  this, let us call it something  $\beta$ , let  $\beta$  be this set, then  $\beta$  is a basis of  $\mathbb{R}^2 \times \mathbb{R}^3$ .

If you carefully observe, we have just pulled back the standard basis of  $\mathbb{R}^5$  which contains five vectors I have not put brackets in certain places, let me do that otherwise it makes no sense. So, there are five elements here and these are essentially obtained by pulling back the standard basis elements.

Let us observe that the dimension of  $\mathbb{R}^2 \times \mathbb{R}^3$  is 5 here that is also the dimension of  $\mathbb{R}^2$  plus the dimension of  $\mathbb{R}^3$  the vectors  $(1, 0, 0, 0, 0)$  and  $(0, 1, 0, 0, 0)$ , are obtained from the basis in  $\mathbb{R}^2$  and the remaining 3 are obtained from the basis in  $\mathbb{R}^3$ , we will make that precise in a moment it is just an observation however, let us look at one more example while just considering  $\mathbb{R}^2$  and  $\mathbb{R}^3$ .

Consider, instead of  $\mathbb{R}^2$  let us consider may be consider the vector space  $P_2$  of  $\mathbb{R}$  instead of  $\mathbb{R}^3$ , let us put  $P_2$  of  $\mathbb{R}$  cross  $\mathbb{R}^2$ . So, what will be a typical element? An element will be something of this type a tuple of this type, may be  $x^2 + 2x + 3$  this is how a typical element in  $P_2$  of  $\mathbb{R}$  cross  $\mathbb{R}^2$  will look like, again I will leave as an exercise for you to check that the following will turn out to be a basis of  $P_2$  of  $\mathbb{R}$  cross  $\mathbb{R}^2$ . Check that  $(1, 0, 0, x^2, 0, 0)$ ,  $(0, 0, 1, 0, 0, 10)$  and  $(0, 0, 1, 0, 0, 1)$  is a basis of  $P_2$  of  $\mathbb{R}$  cross  $\mathbb{R}^2$ .

No surprise is here, we know that  $1, x, x^2$  is a basis of  $P_2$  of  $\mathbb{R}$  and also know that  $(1, 0)$  and  $(0, 1)$  is a basis of  $\mathbb{R}^2$  and we have use that information to conjecture that this will be a basis, off course it is an exercise for you to check that it is indeed a basis it thus, spans and is indeed linearly independent.

Again if you closely observe dimension of  $P_2$  of  $\mathbb{R}$  as 3 we have used the basis of  $P_2$  of  $\mathbb{R}$  and the basis of  $\mathbb{R}^2$  to obtain a new basis. So, that leads us to conjecture the following proposition namely that if you have  $v_1, v_2$  up to  $v_n$ .

(Refer Slide Time: 19:25)

Proposition: Let  $V_1, V_2, \dots, V_n$  be finite dimensional vector spaces over  $\mathbb{R}$ . Then

$$\dim(V_1 \times V_2 \times \dots \times V_n) = \dim(V_1) + \dim(V_2) + \dots + \dim(V_n).$$

Proof: Let  $\beta_i$  be an ordered basis of  $V_i$ .

$$\text{Let } \dim(V_i) = n_i.$$

$$\text{Then } \#\beta_i = n_i \quad (\# \text{ Cardinality})$$

$$\text{Let } \beta = \{(v_1, 0, \dots, 0) : v_1 \in \beta_1\} \cup \{(0, v_2, 0, \dots, 0) : v_2 \in \beta_2\} \\ \cup \dots \cup \{(0, 0, \dots, v_n) : v_n \in \beta_n\}.$$

$$\#\beta = m_1 + m_2 + \dots + m_n$$

So proposition, let  $V_1, V_2$  up to  $V_n$  be finite dimensional vector spaces. I would like to draw your attention here to the fact that when we defined the product, we were not demanding anything about finite dimensionality we could have started off with infinite dimensional vector spaces, talked about vector addition in this manner, scalar multiplication in this manner and we would have still got a vector space  $V_1 \times V_2$  up to  $V_n$ .

So, to talk about product of vector spaces, we really do not need anything about finite dimensionality. However, in order to talk about dimension, we need to have a finite if it is infinite dimensional, then we not interested in talking about the dimension per say. So, we will restrict our attention to finite dimensional vector spaces in order to talk about dimension

this proposition exactly talks about the dimension of the product of  $V_1$  cross  $V_2$  cross up to  $V_n$  when each of these  $V_i$  is a finite dimensional.

So, then dimension of  $V_1$  cross  $V_2$  cross  $V_n$  is equal to dimension of  $V_1$  plus dimension of  $V_2$  plus dimension of  $V_n$ , basically the dimensions add up. Let us give quick proof of this, so we know that  $V_1, V_2$  up to  $V_n$  are finite dimensional, so let  $\beta_i$  be an ordered basis of  $V_i$ . So, we know that  $\beta_i$  has size dimension of  $V_i$ .

So, let us give it a name let dimension of  $V_i$  be equal to  $n_i$ , then the size of cardinality of  $\beta_i$  is equal to  $n_i$ . So, by hash I have just used it to capture cardinality of the set  $\beta_i$ , or the size of the set  $\beta_i$ , the cardinality of  $\beta_i$  is equal to  $n_i$  just give it a name, we will define a basis  $\beta$  of  $V_1$  cross  $V_2$  cross up to  $V_n$ , you seeing these basis vectors  $\beta_i$ .

Let us see how we do that, let  $\beta$  be all the sets of this type  $v$  cross  $v$ , 0 up to 0 union such that  $v$  belongs to, so let me call it  $v_1, v_1$  belongs to  $\beta_1$  union 0,  $v_2, 0, 0$  such that  $v_2$  belongs to  $\beta_2$ , union 0, 0 up to say  $v_n$  where  $v_n$  belongs  $\beta_n$ . So, notice that each of these are a copy of  $\beta_i$ , with the 0 vector in the remaining components and because of that cardinality of  $\beta$  is nothing but cardinality of  $\beta_1$  which is  $m_1$  plus the cardinality of  $\beta_2$  which is  $m_2$  up to the cardinality of  $\beta_n$  which is  $m_n$  and if we manage to proof that this  $\beta$  is indeed a basis of  $v_1$  cross  $v_2$  cross up to  $v_n$ .

Then we would established that the dimension of  $v_1$  cross  $v_2$  cross up to cross  $v_n$  is dimension of  $v_1$  plus up to  $v_n$ , that is precisely  $m_1$  plus  $m_2$  plus up to  $m_n$ .

(Refer Slide Time: 24:35)

Claim:  $\beta$  is a linearly independent set.

Then 
$$\sum_{i=1}^n \sum_{j=1}^{m_i} a_{ij} (0, 0, \dots, v_{ij}^i, \dots, 0) = 0$$
 $\nwarrow$   $j_i^{\text{th}}$  basis elt in  $\beta_i$

---

$$= \left( \sum_{j=1}^{m_1} a_{1j} v_{1j}^1, \sum_{j=1}^{m_2} a_{2j} v_{2j}^2, \dots, \sum_{j=1}^{m_n} a_{nj} v_{nj}^n \right) = 0$$

$\Rightarrow \forall i \sum_{j=1}^{m_i} a_{ij} v_{ij}^i = 0$  in  $V_i$

$$= \left( \sum_{j_1=1}^{m_1} a_{1j_1} v_{1j_1}, \sum_{j_2=1}^{m_2} a_{2j_2} v_{2j_2}, \dots, \sum_{j_n=1}^{m_n} a_{nj_n} v_{nj_n} \right) = 0$$

$$\Rightarrow \forall i \sum_{j_i=1}^{m_i} a_{ij_i} v_{ij_i} = 0 \text{ in } V_i$$

$$\Rightarrow \forall i, \forall j_i \quad a_{ij_i} = 0$$

$\Rightarrow \beta$  is linearly independent.

Exercise:  $\beta$  is indeed a spanning set.

Exercise:  $\beta$  is indeed a spanning set.

$$\text{Hence } \dim(V_1 \times V_2 \times \dots \times V_n) = \dim(V_1) + \dots + \dim(V_n).$$

So, how do we see that beta is a linearly independent sets, so let us starts with that claim beta is a linearly independent set. So, suppose there is a linear combination which is equal to 0, then what would happen is we will be having a relation of the following type, then summation  $a_i j_i$  will not may be the indices should be a bit more carefully chosen, so let me carefully look at to the choices here, then we can write it like this summation  $i$ , equal to 1 to  $n$ ,  $j$  equal to 1 to  $m_i$ ,  $a_{ij_i}$  of let me call the vector, the  $j$ th we write it like this  $v$  may be  $i, j_i$  this captures all the basis elements.

So, this what is this?  $v_{ij_i}$  it is the  $j$ th basis element in  $V_i$ . Alright, but then the scalar multiplication and the vector addition is define in such a manner that this above this is equal to 0. Let us consider some such relation which is equal to 0. our goal is to show that each of these  $a_{ij_i}$ 's are 0 but, these above can be rewritten using the properties of the vector addition

or the product space which we just defined this is equal to summation  $j_1$  going from 1 to  $m_1$   $a_{1j_1}$  of  $v_1$   $j_1$  summation  $j_2$  is going from 1 to  $m_2$  of  $a_{2j_2}$   $v_2$   $j_2$  and so on.

Summation  $a_{ij}$  where  $j$  is going from 1 to  $m_n$  this times  $v_n$   $j$  but, this is equal to 0 implies that each of the things inside, each of the components are individually 0, this implies that for all  $i$   $a_{ij}$  where  $j$  is going from 1 to  $m_i$   $v_i$   $j$  is equal to the 0 vector in  $v_i$  and we know that  $\beta_i$  is linearly independent set which implies for all  $i$ , for all  $j$ ,  $a_{ij}$  is equal to 0 by the linear independence of  $\beta_i$ , and this implies that  $\beta$  is linearly independent.

The spanning property of  $\beta$  can be proved very similarly the indices have to be kept track of very carefully, let me just leave as an exercise for you to check that  $\beta$  is indeed a spanning set as well,  $\beta$  is indeed a spanning set and with this dimension of  $v$  will turn out to be the size of  $\beta$  which is equal to what is  $v$  here by the way it is  $V_1$  cross  $V_2$  cross up to  $V_n$  is equal to the dimension of  $V_1$  plus dimension of  $V_2$  to dimension of  $V_n$ .

So, in the next video we will discuss how more vector spaces can be obtained from existing vector spaces by considering another notion what is called as the Quotient of vector spaces. So let me stop here.
