1. LECTURE 47: RING HOMOMORPHISMS

When we studied groups, we also studied group homomorphisms. They were functions between groups that preserved the group operation similar to that there is the notion of a Ring Homomorphism. So, suppose you have two rings  $R$  and  $S$  then a ring homomorphism is a function  $\phi : R \rightarrow S$  which basically preserves all the structures that are involved in the definition of a ring namely it preserves addition and multiplication. Note that  $\phi$  is a group homomorphism and we take axiomatically that  $\phi(1_R) = 1_S$ .

For example, if you take  $R$  and  $S$  to be any rings and you take  $\phi(x) = 0$  for all  $x$  in  $R$ , then this will satisfy 1 and 2, but it will not satisfy 3 ok and we can talk about isomorphism an isomorphism of rings is a bijective homomorphism and if  $\phi$  from  $R$  to  $S$  is an isomorphism then  $\phi^{-1}$  from  $S$  to  $R$  is also an isomorphism ok let us look at some examples.

While studying groups we had seen that the homomorphism which takes  $x$  to  $x \bmod n$  the residue class of  $x \bmod n$  is a group homomorphism, but this is also a ring homomorphism because residue classes are respected under addition and multiplication.

Let us look at the slightly more interesting example take the ring of polynomials in some field  $x$ . So, this is the set of all polynomials in the variable  $x$  with coefficients in the field  $F$  and you can define a function from  $f$  of  $x$  to  $f$  by just taking the polynomial  $f$  of  $x$  to  $f$  of  $a$  for some fixed  $a$ . So, let us say fix  $a$  in  $F$  for some fixed  $a$  in  $F$ .

Take the ring of polynomials in a variable  $x$  and then you take the ring of polynomials in another variable  $y$  whose coefficients are polynomials in  $x$  ok. So, an element here looks like  $p_0(x) + p_1(x)y + \dots + p_n(x)y^n$  for polynomials  $p_i \in F[X]$ . You can think of a polynomial in  $y$  whose coefficients are polynomials in  $x$  as a polynomial in  $x$  and  $y$  and so, what we are saying is that the ring is isomorphic to polynomials in two variables  $f(x, y)$ . The isomorphism is defined by just expanding out these coefficients and getting polynomials in two variables. So, this is an example of a ring isomorphism.

Another example of a ring isomorphism would be  $\phi : \mathbb{Z}[x] \rightarrow \mathbb{Z}_n[x]$  by reducing the coefficients to their residue classes.
