**Lecture – 57**  
**Koszul complex**

Welcome, this is lecture 57. In this lecture, we look at Koszul complexes, how they are constructed using a mapping cone. We will start with looking at a mapping cone then we will define Koszul complexes as a mapping cone.

(Refer Slide Time: 00:33)

So, what we will quickly review what we, how we defined complexes and then, we will now define maps between complexes and then, we will talk about mapping cones and then so, that is the plan for this lecture.

(Refer Slide Time: 00:49)

## Complexes

Recall: A *complex* of  $R$ -modules is a sequence of  $R$ -modules and  $R$ -module homomorphisms

$$M_{\bullet} : \cdots \rightarrow M_2 \xrightarrow{\mu_2} M_1 \xrightarrow{\mu_1} M_0 \rightarrow 0 \quad \circ$$

such that  $\text{Im}(\mu_i) \subseteq \ker(\mu_{i-1})$  for every  $i \geq 2$ .

or, equivalently,  $\mu_{i-1}\mu_i = 0$  for every  $i \geq 2$ .

It may continue further to the right, even ad infinitum, but we will consider only those like the one above.

So, recall that a complex of  $R$ -modules is a sequence of  $R$ -modules and  $R$ -module homomorphisms, so,  $M_{\bullet} : \cdots \rightarrow M_2 \rightarrow M_1 \rightarrow M_0 \rightarrow 0$  and sometimes you will have to refer to the maps so, we will just label them.

So, why is it a complex? So, that image of  $\mu_i : M_i \rightarrow M_{i-1}$   $\mathfrak{S}(\mu_i) \subset \ker(\mu_{i-1})$  equivalently composition of two consecutive maps is 0. Remember the composition is  $\mu_i$  first and then  $\mu_{i-1}$ .

in principle one does not have to have a 0 here, you could go even to infinity on the right side, but the complexes that we will consider in this course will always end somewhere and then, it is 0 afterwards. So, we will just consider only such complexes.

(Refer Slide Time: 02:01)

Homology of the complex

$$M_{\bullet} : \cdots \rightarrow M_2 \xrightarrow{\mu_2} M_1 \xrightarrow{\mu_1} M_0 \rightarrow 0$$

is the collection of  $R$ -modules

$$H_i(M_{\bullet}) := \ker \mu_i / \operatorname{Im}(\mu_{i+1})$$

We should think of  $\mu_0 = 0$ , so

$$H_0(M_{\bullet}) = \ker \mu_0 / \operatorname{Im}(\mu_1) = \operatorname{coker} \mu_1.$$

The homology of a complex is the  $i$ th homology  $H_i(M_{\bullet}) = \frac{\ker(\mu_i)}{\operatorname{Im}(\mu_{i+1})}$ . So, remember that image of  $\mu_{i+1}$  is always inside the kernel of  $\mu_i$ . So, the quotient, the module is called the homology of this complex, the  $i$ th homology of this complex.

And we can at this point, we can think of the last map from  $M_0 \rightarrow 0$  you can think of it as a

map  $\mu_0$  and as a 0 map. And hence,  $H_0(M_{\bullet}) = \frac{\ker(\mu_0)}{\operatorname{Im}(\mu_1)} = \frac{M_0}{\operatorname{Im}(\mu_1)}$ .

. which is what is called, what we call the  $\operatorname{coker}(\mu_1)$ . So, remember that the last the  $H_0$  of such a complex is a co-kernel of this last map  $M_1 \rightarrow M_0$ .

(Refer Slide Time: 03:15)

**Definition**

Let  $(F_\bullet, f_\bullet)$  and  $(G_\bullet, g_\bullet)$  be complexes as above. A *map of complexes*  $\alpha_\bullet : F_\bullet \rightarrow G_\bullet$  is a collection of  $R$ -module maps  $\alpha_i : F_i \rightarrow G_i$   $i \geq 0$  such that the following diagram commutes:

$$\begin{array}{ccccc} \longrightarrow & F_i & \xrightarrow{f_i} & F_{i-1} & \longrightarrow \\ & \downarrow \alpha_i & & \downarrow \alpha_{i-1} & \\ \longrightarrow & G_i & \xrightarrow{g_i} & G_{i-1} & \longrightarrow \end{array}$$

In other words,

$$g_i \alpha_i = \alpha_{i-1} f_i$$

If we have two complexes  $(F_\bullet, f_\bullet)$  where we denote the maps by small  $f$  and  $(G_\bullet, g_\bullet)$  where we denote the maps by small  $g$ , if their complexes as above so, ending at some 0 and then 0 modulus of 0 afterwards. A map of complexes is a collection of  $R$ -module homomorphism from  $\alpha_i : F_i \rightarrow G_i$  for each  $i$  so, such that the following diagram commutes.

What does that mean to say diagram commutes? It means that between any pair of points all the arrows going from one to the other are either give the same function. So, in this case, it is only one to check which is from  $F_i \rightarrow G_{i-1}$ , there are two paths  $F_i \rightarrow F_{i-1} \rightarrow G_{i-1}$ .

And  $F_i \rightarrow G_i \rightarrow G_{i-1}$  so, along the sides of this rectangle there are two different paths and they those two functions agree. So, in other words,  $g_i \alpha_i$  which is the path down first and then to the right that is the same as right first and then down  $\alpha_{i-1} f_i$ . So, these two composites are the same that is what diagram commutes means and that is what it means in this context of a map of complexes.

(Refer Slide Time: 04:39)

### Proposition

Let  $\alpha_\bullet : F_\bullet \rightarrow G_\bullet$  be a map of complexes. Then there is an induced map in homology:

$$H_i(\alpha) : H_i(F_\bullet) \rightarrow H_i(G_\bullet)$$

### Proof.

$$\begin{array}{ccccccc} \longrightarrow & F_{i+1} & \xrightarrow{f_{i+1}} & F_i & \xrightarrow{f_i} & F_{i-1} & \longrightarrow \\ & \downarrow \alpha_{i+1} & & \downarrow \alpha_i & & \downarrow \alpha_{i-1} & \\ \longrightarrow & G_{i+1} & \xrightarrow{g_{i+1}} & G_i & \xrightarrow{g_i} & G_{i-1} & \longrightarrow \end{array}$$

Pick  $a \in \ker f_i$ .  $f_i(a) = 0$ .  $b := \alpha_i(a)$ .  $g_i(b) = 0$ .

We see that  $\alpha_i(\ker f_i) \subseteq \ker g_i$ . The map is  $\alpha_i|_{\ker f_i}$ .

Suppose  $a = f_{i+1}(a_1)$ . Then  $b = g_{i+1}\alpha_{i+1}(a_1)$ , i.e.,  $b \in \text{Im}(g_{i+1})$ .

Hence, under the above map,  $\text{Im}(f_{i+1})$  goes inside  $\text{Im}(g_{i+1})$ .  $\square$

So, if you have a map of complexes, then it induces a map in homology that is a map  $\alpha : F \rightarrow G$ , induces a map which we will denote by  $H_i(\alpha) : H_i(F_\bullet) \rightarrow H_i(G_\bullet)$ . So, we will so, these proofs are done using what is called a diagram chasing. So, we will just do the diagram chasing on this diagram itself

So, we need to find an element, we need to look for elements in the kernel here that is

$\frac{\ker(f_i)}{\text{Im}(f_{i+1})}$  and we need to get them to an element in  $\frac{\ker(g_i)}{\text{Im}(g_{i+1})}$ . So, from the kernel in the top

row at  $F_i$  to the to the homology of the bottom row that is inside  $G_i$ . So, we will do this by doing what is called a diagram chasing.

So, let us pick an  $a \in \ker(f_i)$ . Remember elements of homology are kernel mod image so, they are represented by the residue classes of elements of the kernel going modulo image of the previous map. So, we will just take an element in the kernel. So, it is in kernel. So, it just means that  $f_i(a) = 0$ . So, the things that I mark in red are the elements that we pick and yes, we will see how the elements progress in this diagram chase.

So,  $f_i(a) = 0$ . Now define  $b := \alpha_i(a)$ . Now, because the diagram commutes,  $g_{i-1}(b) = 0$ . So, we chose  $a \in \ker(f_i)$  so, it went to 0 here and then came to 0 here so, along top and right, we have we get 0 inside this  $G_{i-1}$ . Therefore, on the left and bottom also one should get this. So,

$$b \in \ker(g_i).$$

So, in other words, what we just observe is that  $\alpha_i(\ker(f_i)) \subseteq \ker(g_i)$ . So, we can think of this as a map  $\alpha_i$  restricted to  $\ker(f_i)$ . Now, let us check what happens under this map to  $\text{im}(f_{i-1})$ . Remember that,  $\text{im}(f_{i+1}) \subseteq \ker(f_i)$ . So, under this map, what would happen to image of  $f_{i-1}$ .

So, now let us take, let now let us assume that  $a$  is in the image of the previous map. So, in other words,  $a = f_{i+1}(a_1)$ . So, this  $a$  is a image of this  $a_1$ , then because of the commutativity of the diagram one can immediately see that this  $b = g_{i+1}\alpha_{i+1}(a_1)$ . In other words,  $b \in \text{im}(g_{i+1})$ . So, if  $a$  is the image of the top row map, then so, is this  $b$  that is the conclusion.

In other words, under this map  $\alpha_i$  restricted to this kernel,  $\alpha_i(\text{im}(f_{i+1})) \subseteq \text{im}(g_{i+1})$ . So, now what do we have? We have a map from the kernel in the top row to the kernel in the bottom row under which the image in the top row goes inside the image of the bottom row when you this is.

So, now, this gives a map from kernel mod image on the top row to kernel mod image in the bottom row and that is exactly what  $H_i(F) \rightarrow H_i(G)$  is. So, in so, what the that is the end of the proof. So, the conclusion is that any map of complexes through this diagram chasing show gives a map in homology.

(Refer Slide Time: 08:55)

## Mapping cones

Aim: Given  $\alpha_\bullet : F_\bullet \rightarrow G_\bullet$  a map of complexes, we would like to fit the maps

$$H_i(\alpha) : H_i(F_\bullet) \rightarrow H_i(G_\bullet)$$

into an exact sequence of  $R$ -modules 'nicely'.

$$\cdots \rightarrow M_{i+1} \rightarrow H_i(F_\bullet) \rightarrow H_i(G_\bullet) \rightarrow M_i \rightarrow H_{i-1}(F_\bullet) \rightarrow H_{i-1}(G_\bullet) \rightarrow M_{i-1} \cdots$$

'nicely': means that we would to construct the  $M_i$  in a way from which will help up get information about  $\alpha_\bullet$ .

So, now we wanted to look at this thing called mapping cones which is a way. So, here is a motivation or our aim. So, we have given a map of complexes. So, we have these maps now. We would like to fit them into some exact sequence like this. So, this is the map; this is the map in homology at the  $i$ th level so, this is at the  $i$ th level.

This is the map in homology at the  $i - 1$ th level and we would like to put them in such a long exact sequence because it would help us conclude various things. So, this is again I mean post facto justification, we would like to put them like this in a nice way and what does what do we exactly mean by nicely?

So, we would like to describe these  $M_i$  in such a way that we can say something about the maps  $\alpha_i$  or they are somehow in some constructed in some natural way we, there is no definition I mean is to what exactly we should I mean how, what exactly the natural way is, but we will describe one such thing called mapping cones.

So, the aim is to understand the induced map in homology, how does it fit together, what is its kernel and co kernel. So, these things would be clarified with if you put them in a nice exact sequence like this. So, the aim is to construct such a nice exact sequence.

(Refer Slide Time: 10:29)

$$\begin{array}{ccccccc}
 \longrightarrow & F_2 & \xrightarrow{f_2} & F_1 & \xrightarrow{f_1} & F_0 & \longrightarrow 0 \\
 & \downarrow \alpha_2 & & \downarrow \alpha_1 & & \downarrow \alpha_0 & \\
 \longrightarrow & G_2 & \xrightarrow{g_2} & G_1 & \xrightarrow{g_1} & G_0 & \longrightarrow 0
 \end{array}$$

Define  $C_\bullet := C_\bullet(\alpha_\bullet)$  *mapping cone* of  $\alpha_\bullet$ .

$$\begin{array}{ccccccc}
 G_3 & \begin{bmatrix} g_3 & \alpha_2 \\ 0 & -f_2 \end{bmatrix} & G_2 & \begin{bmatrix} g_2 & \alpha_1 \\ 0 & -f_1 \end{bmatrix} & G_1 & \begin{bmatrix} g_1 & \alpha_0 \end{bmatrix} & G_0 \longrightarrow 0 \\
 \oplus & \longrightarrow & \oplus & \longrightarrow & \oplus & \longrightarrow & \\
 F_2 & & F_1 & & F_0 & & 
 \end{array}$$

So, this is what we start with. So, we have to now going to describe the construction of the mapping cone. We have a complex  $F$  on the top row, complex  $G$  in the bottom row and I have drawn it from the rightmost end where  $F_0 \rightarrow G_0$  and then towards to its right these are all

0 modules. So, we have a map like this.

So, now, we would like to describe what is called the mapping cone of this map of complexes. So, here is the thing let us see how this was constructed. So, now, let us look at  $G_0$ . There are two maps coming to  $G_0$ , one  $\alpha_0: F_0 \rightarrow G_0$  and one  $g_1: G_1 \rightarrow G_0$ .

So,  $F_0$  and  $G_1$  mapped to  $G_0$ . So, in this mapping cone, we put this here  $G_1 \oplus F_0 \rightarrow G_0$  and the map  $[g_1 \alpha_0]$  from the first factor, we use the map  $g_1$ , for the second factor which is  $F_0$  we use  $\alpha_0$ . So, that just came directly from this.

So, here is  $G_0$ , we just map to all the modules that map into this which is from the  $F$  complex and the  $G$  complex, one module each so, that is what we have here. . Now, we have now in the second position of this complex this is new complex, we have  $G_1 \oplus F_0$  so, the things on this diagonal like this.

And there are two modules behind them which map to these that is there is  $G_2$  and then there is  $F_1$ .  $\alpha_1: F_1 \rightarrow G_1$  and  $f_1: F_1 \rightarrow F_0$  and  $g_2: G_1 \rightarrow G_0$ .

So, let us put that thing together here. So, this is written as like a matrix, but it is not exactly a matrix, it is just a convenient way of writing; because it is a map from a direct sum. So,  $G_2 \oplus F_1 \rightarrow G_1 \oplus F_0$ . From the first part here to the first part here which is  $G_2 \rightarrow G_1$ , we have a map  $g_2$ .

Then, from the first part here to  $F_0$ , the second part here there is no map so, it is 0. From  $F_1$  which is the second part here to the first summand which is  $G_1$  there is a map  $\alpha_1$  so, we have this. And from  $F_1$  to  $F_0$ , there is a map little  $f_1$ , but we just put it a minus sign and we will see why this is needed.

So, we so, we just put a only thing you keep in mind is that there is a minus sign there. Similarly, from we have  $G_2 \oplus F_1$ , the map would be from  $G_3 \oplus F_2 \rightarrow G_2 \oplus F_1$ ,  $G_3$  to  $G_2$  there is a  $g_3$  map,  $G_3$  to  $F_1$  there is no map,  $F_2$  to  $G_2$  there is an  $\alpha_2$  and  $F_2$  to  $F_1$  we have a map  $f_2$ , but we use that with a minus sign.

(Refer Slide Time: 14:11)

$C_\bullet$  is a complex:

$$\begin{array}{ccccccc} G_3 & \begin{bmatrix} g_3 & \alpha_2 \\ 0 & -f_2 \end{bmatrix} & G_2 & \begin{bmatrix} g_2 & \alpha_1 \\ 0 & -f_1 \end{bmatrix} & G_1 & \begin{bmatrix} g_1 & \alpha_0 \end{bmatrix} & G_0 \\ \oplus & \xrightarrow{\quad} & \oplus & \xrightarrow{\quad} & \oplus & \xrightarrow{\quad} & \xrightarrow{\quad} \\ F_2 & & F_1 & & F_0 & & \xrightarrow{\quad} 0 \end{array}$$

Since  $g_i \alpha_i = \alpha_{i-1} f_i$  for every  $i$ :

$$\begin{aligned} \begin{bmatrix} g_1 & \alpha_0 \end{bmatrix} \begin{bmatrix} g_2 & \alpha_1 \\ 0 & -f_1 \end{bmatrix} &= \begin{bmatrix} g_1 g_2 & g_1 \alpha_1 - \alpha_0 f_1 \end{bmatrix} = 0 \\ \begin{bmatrix} g_2 & \alpha_1 \\ 0 & -f_1 \end{bmatrix} \begin{bmatrix} g_3 & \alpha_2 \\ 0 & -f_2 \end{bmatrix} &= \begin{bmatrix} g_2 g_3 & g_2 \alpha_2 - \alpha_1 f_2 \\ 0 & f_1 f_2 \end{bmatrix} = 0 \end{aligned}$$

and so on.

Write  $\delta_i$  for the map  $C_i \rightarrow C_{i-1}$ .

So, now we have this, and the point is that. So, this I have just copied it. This is the same complex that we just described in the previous page. The point is that this is a complex why? So, let us check this. So, which means we should check that this map here, this map this map here the square the two, I mean the  $G_2 \oplus F_1 \rightarrow G_1 \oplus F_0$  this map here to the next map the composite should be 0.

So, remember the maps are applied in the opposite order, this is the one that supplied first and then, this 2 by 1 sorry this 1 by 2 looking matrix. So, this is the composition and one can immediately check that because of the; because of the diagram commutes  $g_1 \alpha_1 = \alpha_0 f_1$  and because we introduced a minus sign, they cancel each other and we get 0 map and similarly here also.

The diagram commutes so,  $g_2 \alpha_2 = \alpha_1 f_2$ , but we introduced a minus sign precisely to cancel this and so, we get 0 in this in this part and  $g_2 g_3$  is anyway 0 because it is a complex and  $f_1 f_2$  is also 0 because it is a complex and so on to the left.

So, except at this at the rightmost place where you know you one has to multiply a matrix like this, rest of it is all like these two by these are not matrices, but you know two fact, two summons on both from each one of those complexes. So, we get this. So, this is a complex.

So, now, we will need to work with this complex a little bit. We will write  $\delta_i$  for these maps. So, delta so, this is  $G_0 = C_0$ , this thing here is  $C_1 = G_1 \oplus F_0$ ,  $C_2 = G_2 \oplus F_1$ ; the index of G, the

subscript for  $G$  is the one which describes the subscript for  $C$ . So, this is how. So, the map we will describe as  $\delta_i$ .

(Refer Slide Time: 16:17)

We have a short exact sequence of complexes:  
 $G_i \rightarrow C_i$  is the inclusion as the first summand.  
 $C_i \rightarrow F_{i-1}$  is the projection to the second summand.  
 Rows are exact.  
 All the squares commute.

$$\begin{array}{ccccccc}
 0 & \longrightarrow & G_{i+2} & \longrightarrow & C_{i+2} & \longrightarrow & F_{i+1} \longrightarrow 0 \\
 & & \downarrow g_{i+2} & & \downarrow \delta_{i+2} & & \downarrow -f_{i+1} \\
 0 & \longrightarrow & G_{i+1} & \longrightarrow & C_{i+1} & \longrightarrow & F_i \longrightarrow 0 \\
 & & \downarrow g_{i+1} & & \downarrow \delta_{i+1} & & \downarrow -f_i \\
 0 & \longrightarrow & G_i & \longrightarrow & C_i & \longrightarrow & F_{i-1} \longrightarrow 0
 \end{array}$$

So, now, from what we have constructed, we have what is called a short exact sequence of complexes. So, I will not define it, I mean I will just I will describe these things in this context, but we will do an exercise which describes it in I mean in in full generality.

So, what exactly do we mean? Actually, what are these maps first of all? The vertical maps  $g_i$  and vertical maps  $f_i$  and here  $-f_i$  they were given to us. These delta i's were constructed as I mean in the previous pages. So, the now, we have to describe the horizontal maps.

The, this is the inclusion in the first summand. Remember  $G_i \rightarrow C_i = G_i \oplus F_{i-1}$  so, the inclusion from  $G_i$  to  $C_i$  is the inclusion as the first summand and  $C_i = G_i \oplus F_{i-1} \rightarrow F_{i-1}$  is the projection to the second summand. So, therefore, the rows are exact. So, that is what here we mean.

So, this is important rows are exact and all the squares in these commute that is because in other word, we are saying is that we will see it in a minute. I mean rows commute one can check explicitly because the first factor if you go here and apply delta, it is same thing as applying  $g$  because nothing happens to the second and so, it is. So, one can write down from those matrices and check that the all those squares commute.

(Refer Slide Time: 18:03)

Fact: Every short exact sequence of complexes

$$0 \rightarrow C'_\bullet \rightarrow C_\bullet \rightarrow C''_\bullet \rightarrow 0$$

gives an exact sequence in homology:

$$\cdots \rightarrow H_i(C'_\bullet) \rightarrow H_i(C_\bullet) \rightarrow H_i(C''_\bullet) \rightarrow H_{i-1}(C'_\bullet) \rightarrow H_{i-1}(C_\bullet) \rightarrow H_{i-1}(C''_\bullet) \rightarrow \cdots$$

We will prove this for the case involving the mapping cone.

General case will be an exercise.

Now, here is a general fact about short exact sequence of complexes. So, we will make a proper definition of this etcetera and prove this fact in this generality in the exercises. So, we for every short exact sequence of complexes  $0 \rightarrow C' \rightarrow C \rightarrow C'' \rightarrow 0$ , there is an exact sequence in homology  $\cdots \rightarrow H_i(C') \rightarrow H_i(C) \rightarrow H_i(C'') \rightarrow H_{i-1}(C') \rightarrow H_{i-1}(C) \rightarrow H_{i-1}(C'') \rightarrow \cdots$ .

So, this is a general fact we will . So, we will prove this just for this mapping cone case explicitly general case as I said will be an exercise.

(Refer Slide Time: 18:49)

$$\begin{array}{ccccccc} 0 & \longrightarrow & G_{i+1} & \longrightarrow & C_{i+1} & \longrightarrow & F_i \longrightarrow 0 \\ & & \downarrow g_{i+1} & & \downarrow \delta_{i+1} & & \downarrow -f_i \\ 0 & \longrightarrow & G_i & \longrightarrow & C_i & \longrightarrow & F_{i-1} \longrightarrow 0 \\ & & \downarrow g_i & & \downarrow \delta_i & & \downarrow -f_{i-1} \\ 0 & \longrightarrow & G_{i-1} & \longrightarrow & C_{i-1} & \longrightarrow & F_{i-2} \longrightarrow 0 \end{array}$$

$G_\bullet \rightarrow C_\bullet$  is a map of complexes, so we get  $H_i(G_\bullet) \rightarrow H_i(C_\bullet)$  for every  $i$ .

The last column is not  $F_\bullet$ , but with a minor modification.

At the  $i$ th position, we have  $F_{i-1}$ , and the maps are multiplied by  $-1$ .

Call this modified complex  $F'_\bullet$ . Note:  $H_i(F'_\bullet) = H_{i-1}(F_\bullet)$ .

$C_\bullet \rightarrow F'_\bullet$  is a map of complexes, so we get  $H_i(C_\bullet) \rightarrow H_i(F'_\bullet)$  for every  $i$ .

So, the squares here commute says that if you look at the vertical; vertical arrows, the collection form the complex  $G$  and the middle arrows here vertical things form the complex  $C$  and the arrows commute is the same thing as saying the left from the complex  $G$  to the complex  $C$  is a map of complexes. So, we get this we observed earlier, there is a map of homology from  $H_{i-1}(G) \rightarrow H_i(C)$  there is a natural map which came from the map of complexes.

Now, just observe that the last column is not the complex  $F$ , but there is a minor modification which is that its indices have been shifted by 1. At the  $i$ th position of the new complex, we have  $F_{i-1}$  and the maps are multiplied by minus 1. So, there is a shift in the indices and the multiplication by a minus 1 in the maps. So, we will call this new complex  $F'$  just a notation.

The observation that we need to make is  $H_i(F') = H_{i-1}(F)$ . The kernel and image do not change if you multiply by -1 and all that we have done I mean for while computing homology only thing that we have done is just changing the indices so, what homology we would have obtained at  $i-1$  position if we are treating it as  $F$ , we would now get it at  $i$ th position. So, now,  $C \rightarrow F'$  is a map of complexes and so, we get a map  $H_i$  of  $C$  to  $H_i$  of  $F'$  prime, but remember that is  $H_{i-1}$  of  $F$  for every  $i$  ok.

So, then one needs to check so, this is just a sort of preliminary discussion, one has to check that if you take this map, I mean  $H_i(G) \rightarrow H_i(C) \rightarrow H_i(F')$ , it is exact at the middle part which is  $H_i(C)$  that we would not describe, it will come from the general principle about short exact sequence of complexes giving long exact sequence on homology. So, I, we would not explicitly check in this lecture, but let us see how the mapping, what specific thing happens in the mapping cone.

(Refer Slide Time: 21:11)

$$\begin{array}{ccccccc}
 0 & \longrightarrow & G_{i+2} & \longrightarrow & C_{i+2} & \longrightarrow & F_{i+1}b' \longrightarrow 0 \\
 & & \downarrow g_{i+2} & & \downarrow \delta_{i+2} & & \downarrow -f_{i+1} \\
 0 & \longrightarrow & G_{i+1}a & \longrightarrow & C_{i+1}(a, b) & \longrightarrow & F_i b \longrightarrow 0 \\
 & & \downarrow g_{i+1} & & \downarrow \delta_{i+1} & & \downarrow -f_i \\
 0 & \longrightarrow & G_i ga + \alpha b & \longrightarrow & C_i(ga + \alpha b, 0) & \longrightarrow & F_{i-1}0 \longrightarrow 0
 \end{array}$$

Take  $b \in \ker f_i$ . Lift it to  $(a, b) \in C_{i+1}$ , with any  $a \in G_{i+1}$ . This gives  $(g_{i+1}a + \alpha_i b, 0) \in C_i$ . In other words,  $g_{i+1}a + \alpha_i b \in G_i$ . Note that  $g_i(g_{i+1}a + \alpha_i b) = 0$ .

Well-defined map  $\ker f_i \rightarrow H_i(G_\bullet), b \mapsto \alpha_i(b) \mod \text{Im } g_{i+1}$ .  
Does not depend on the choice of  $a$ .

Suppose  $b = -f_{i+1}(b')$ . Then  $\alpha_i b = -\alpha_i f_{i+1}b' = -g_{i+1}\alpha_{i+1}b' \in \text{Im}(g_{i+1})$ . Hence the map  $H_i(F_\bullet) \rightarrow H_i(G_\bullet)$  is given by  $\alpha$ .

So, I have left some gaps to fill in elements here, we are going to do a diagram chase. So, now so, let us go back. Composing these two,  $H_i(G) \rightarrow H_i(C) \rightarrow H_i(F')$  prime we get something like this.

(Refer Slide Time: 21:31)

Fact: Every short exact sequence of complexes

$$0 \rightarrow C'_\bullet \rightarrow C_\bullet \rightarrow C''_\bullet \rightarrow 0$$

gives an exact sequence in homology:

$$\cdots \rightarrow H_i(C'_\bullet) \rightarrow H_i(C_\bullet) \rightarrow H_i(C''_\bullet) \rightarrow H_{i-1}(C'_\bullet) \rightarrow H_{i-1}(C_\bullet) \rightarrow H_{i-1}(C''_\bullet) \rightarrow \cdots$$

The middle part is  $C$ , left one is  $G$  and right side is  $F'$  so, we get something like this. What we want is the switch from the  $i$ th stage to  $i - 1$ th stage. So,  $H_i(F') \rightarrow H_{i-1}(G)$  so, it is this map that it is this map here that we are trying to construct in the what we will describe now so, yeah.

So, we need something to go from this homology here remember this  $F_i = F'_{i+1}$ . So, from this point to this I mean the homology of the right most complex at this point; at this point to the homology of the left most complex at this point that is what we will need to construct.

So, let us take a  $b$ . So, well do a diagram chase like earlier. So, we will take a let us take a  $b \in \ker(f_i)$ .  $\ker(f_i) = \ker(-f_i)$ . So, this  $b$  here goes to 0. Now, lift it to any  $(a, b)$ . So, remember  $C_{i+1} = G_{i+1} \oplus F_i$ . So, lift it to any  $a, b$ , where  $a \in G_{i+1}$ . So, it does not matter what  $a$  is lift it here.

Let us apply delta, let us come down to this map. Well, when you come down to this map,  $g$  gets applied to  $a$  because  $a$  came from this,  $\alpha$  gets applied to  $b$  because  $\alpha$  came from here,  $b$  came from here and then for the second summand I mean the second component  $f$  gets applied to  $b$  ok. So, what we have is  $(g_{i+1}a + \alpha_i b, 0) \in C_i$ .

So, I have just in this thing, I have just to conserve some space, I will just call it  $ga + \alpha b$ , but usually after a while keeping track of these indices unless there is a pressing need for it one does not, I mean 1 understands that this is after applying the correct  $g$  in the correct degree. So, we get an element here and remember that the map from I mean in the second factor the map is  $b \rightarrow f(b)$ , but  $b \in \ker(f_i)$  so, it is 0. So, one has this.

In other words, this element here came from  $G_i$ . So, this is the element that we. So, from here we lift it arbitrarily, then we apply this map and then, we got an element inside  $G$ . If you apply; if you apply the  $g$  map to this  $ga + \alpha b$ , we would get 0 because this one can just check this is just check map two consecutive maps in a complex and for this factor, one has to use that the diagram commutes  $g_i \alpha_i = \alpha f b$ , but  $f(b) = 0$  so, one gets 0 here.

So, in other words, what we have is we have a well-defined map from the  $\ker(f_i) \rightarrow H_i(G)$  not to the kernel because the actual map depends on the choice of  $a$ . So, there is no well-

defined map from  $\ker(f_i) \rightarrow \ker(g_i)$ , there is a map  $\ker(f_i) \rightarrow \frac{\ker(g_i)}{\text{im}(g_{i+1})}$

. So, so, one has to make it a well-defined map, R linear map, one has to go modulo the  $\text{im}(g_{i+1})$  so, this is the map,  $\ker(f_i) \rightarrow H_i(G)$  where  $b \rightarrow \alpha_i(b)$ .

And this map does not depend on the choice of  $a$  because whatever if you chose an  $a$  prime here, if you do the same thing calculation here, you will get a different element here, but that different element will depend will be inside the  $\text{im}(g_{i+1})$ . So, in the homology it would be the same element.

So, one has to check that this is  $R$ -linear etcetera in which it is. So, now; we got we get a map from  $\ker(f_i) \rightarrow H_i(G)$  which came through the map of complexes  $\alpha$ , it is an element in the kernel to which the map  $\alpha_i$  is applied so, this is what we have.

Now, what we had wanted was from  $H_i(F') \rightarrow H_{i-1}(G)$ , in order to do this, we need to understand what happens to the image of the previous map. So, now, suppose that  $b$  is actually the image of the previous map so,  $b = -f_{i+1}(b')$ , then one can just immediately check this  $\alpha_i(b) = -\alpha_i f_{i+1}(b')$  so, now one immediately sees that if  $b$  is in the image of this, then  $\alpha_i(b) \in \text{im}(g_{i+1})$ .

In other words, the image  $\text{im}(f_{i+1})$  goes to the image of this thing so, inside the homology it is 0. So, hence, we get a map from  $H_i(F) \rightarrow H_{i-1}(G)$  given by  $\alpha$ .

Remember this is how the mapping homology was defined. I mean if you have an element  $b$  in the kernel, we the map takes the  $\bar{b}$  to  $\overline{\alpha_i b}$  and that is exactly what this map does.

(Refer Slide Time: 27:51)

Summary:

Given  $\alpha_\bullet : F_\bullet \rightarrow G_\bullet$  a map of complexes, we have an exact sequence

$$\cdots \rightarrow H_{i+1}(G_\bullet) \rightarrow H_i(F_\bullet) \rightarrow H_i(G_\bullet) \rightarrow H_i(C_\bullet) \rightarrow H_{i-1}(F_\bullet) \rightarrow H_{i-1}(G_\bullet) \rightarrow H_{i-1}(C_\bullet) \rightarrow \cdots$$

$\circ$

And now so, with this we have established so, let us just summarize. Given  $\alpha$  map of complexes we have an exact sequence. So, let us just make sure we get this thing. So, this is  $F_i$ , the homology here is  $H_i(F)$ , homology here is  $H_i(G)$  so, the map that we have constructed is from here to here and then, we have this. So,  $\rightarrow H_{i+1}(C) \rightarrow H_i(F) \rightarrow H_i(G) \rightarrow H_i(C) \rightarrow H_{i-1}(F) \rightarrow$ . So, this is how this thing comes.

(Refer Slide Time: 28:27)

Let  $R$  be a ring and  $f_1, \dots, f_t \in R$ .  
The *Koszul complex* on  $f_1$  is the complex

$$K_\bullet(f_1) : 0 \rightarrow R \xrightarrow{\cdot f_1} R \rightarrow 0$$

Inductively assume that  $K_\bullet(f_1, \dots, f_i)$  has been defined.

◦

Multiplication by  $f_{i+1}$  gives a map of complexes

$$K_\bullet(f_1, \dots, f_i) \rightarrow K_\bullet(f_1, \dots, f_i)$$

The *Koszul complex* on  $f_1, \dots, f_{i+1}$  is the mapping cone of the above map of complexes.

Now, we come to this point of defining Koszul complexes. So, we have a ring and  $f_1, \dots, f_t$  elements in  $R$ . The Koszul complex on  $f_1$ , a single element is the complex  $K_\bullet(f_1) : 0 \rightarrow R \xrightarrow{\cdot f_1} R \rightarrow 0$  multiplication by  $f_1$ . Inductively, let us assume that up to for  $i$  elements we have defined it.

Now, multiplication by  $f_{i+1}$  gives a map of complexes just a map of complexes and the  $K_\bullet(f_1, \dots, f_{i+1})$  is a mapping cone of the above map of complexes. So, if there are two and we will see in Macaulay, how these things are constructed?

(Refer Slide Time: 29:15)

Output

We want to construct the degree preserving map of graded modules of rank 1, given by multiplication by  $x$ .

Input

```
map(R^1, R^1, {{x}})
isHomogeneous oo
```

Output

```
| x |
    1      1
Matrix R <--- R
false
```

Not degree preserving!

Input

```
phix = map(R^{0}, R^{-1}, {{x}})
isHomogeneous phix
```

So, now we define a map from rank 1 R-module to rank 1 R-module multiplication by  $x$  and we ask `isHomogeneous oo` and it says its false and the reason is both generators in both these modules basis elements have degree 0 and hence, multiplication by  $x$  would not preserve degree, it is just saying it is not a homogeneous map.

(Refer Slide Time: 29:39)

```
Matrix R <--- R
false
```

Not degree preserving!

Input

```
phix = map(R^{0}, R^{-1}, {{x}})
isHomogeneous phix
```

Output

```
| x |
    1      1
Matrix R <--- R
true
```

Let us check what these are:

1

So, we can make it homogeneous by giving degrees like this. So, this is a rank 1 free module where a basis element has degree; where a basis element has degree 0, this basic this is  $R^{\{-1\}}$  so, basic there is a basis in which the element has degree, generator has degree 1 and

multiplication by  $x$  now preserves degree.

(Refer Slide Time: 30:01)

Input

```
R^{0}
R^{-1}
```

Output

```
1
R
R-module, free

1
R
R-module, free, degrees {1}
```

Input

```
Kx = koszul phix
v ~ 0
```

Yeah so, let us just ask what these things are.  $R^{\{0\}}$ , just a  $R$ -module free.  $R^{\{-1\}}$  is  $R$ -module free, degrees is 1, the generated degree is 1.

(Refer Slide Time: 30:21)

Input

```
Kx = koszul phix
Kx_0
Kx_1
Kx.dd
```

Output

```
1      1
R <-- R

0      1
ChainComplex

1
R
R-module, free

1      0
R
R-module, free, degrees {1}
```

We ask Macaulay to construct the Koszul complex. So, Koszul complex is asked for a map. So, Koszul of  $\text{phix}$  was that multiplication by  $x$ . So, we call it  $Kx$ . Then, we ask so, this one these three commands will tell you the first element the module in the complex and the differentials in the complex, the maps in the complex

So, it says so, it showed us this complex 0 and 1 it says the chain complex. First module I mean 0th module here is  $R^1$  free, second module is  $R^1$  free, but the generated degree is 1.

(Refer Slide Time: 30:59)

```

1
R
R-module, free

1
R
R-module, free, degrees {1}

1      1
0 : R <----- R : 1
    | x |

ChainComplexMap
0

```

Input

```

phi_y = map(R^{0}, R^{-1}, {{y}})
K_y = koszul phi_y

```

And if you ask for its map, it says this is the map. So, now we define similarly  $\phi_{iy}$  and we ask for Koszul, we can ask for the Koszul complex.

(Refer Slide Time: 31:03)

## 2 Map of complexes, mapping cone

Input

```

Kx1 = Kx**R^{-1}
Kx1_0
Kx1_1
Kx1.dd

```

Output

```

1      1
R <-- R

0      1

ChainComplex

1
R
R-module, free, degrees {1}

1
R

```

So, now, mapping cones. So, now, we need multiplication by  $y$  to be homogeneous. So, we cannot use  $Kx$  itself, we need to change its degrees. If multiplication by  $y$  has to be

homogeneous, then it has to be, it has to come from  $R^{-1}$  to  $R^0$ .

So, we shift, we take  $Kx$  itself, but when we in order to be able to multiply by  $y$ , we shift the degree and call it. So, the  $Kx \otimes R^{-1}$  it has a correct interpretation in terms of tensor products, but for us we will just treat it as shifting degrees.

(Refer Slide Time: 31:55)

```

Kx1_0
Kx1_1
Kx1.dd

```

Output

```

1 1
R <- R
0 1
ChainComplex
1
R
R-module, free, degrees {1}
1
R
R-module, free, degrees {2}
1 1

```

So, now we get. So, we asked for  $Kx1$ . So, the first the 0th module now is in degree 1 and the first module is in degree 2, generator is in degree 2.

(Refer Slide Time: 32:07)

```

R
R-module, free, degrees {1}
1
R
R-module, free, degrees {2}
1 1
0 : R <----- R : 1
      {1} | x |
ChainComplexMap

```

For us,  $Kx \otimes R^{-1}$  is just a way to increase the degrees of the basis elements of the modules

3

And the map is still multiplication by  $y$  and as I said for us  $Kx \otimes R^{-1}$  is just a way to change the degrees of the basis element ok.

(Refer Slide Time: 32:15)

in  $Kx$  by 1.

The correct explanation involves tensor products, which we have not discussed.

$\{1\}$  that precedes the description of the matrix  $|x|$  says that the basis element of the target of the map has degree 1.

Hence the basis element of the source of the map has degree 2.

Input

$$\text{MapKxKy} = \text{extend}(Kx, Kx1, \text{matrix } \{\{y\}\})$$

Output

$$\begin{array}{ccc} & 1 & 1 \\ 0 : R & \xleftarrow{\quad} & R : 0 \\ & |y| & \\ & 1 & 1 \\ 1 : R & \xleftarrow{\quad} & R : 1 \\ & \{1\} |y| & \end{array}$$

ChainComplexMap

The 1 here that precedes  $x$  as the target has degree 1 so, the source has degree 2 yeah. So, that is just, I am just stating.

(Refer Slide Time: 32:35)

of the map has degree 1.

Hence the basis element of the source of the map has degree 2.

Input

$$\text{MapKxKy} = \text{extend}(Kx, Kx1, \text{matrix } \{\{y\}\})$$

Output

$$\begin{array}{ccc} & 1 & 1 \\ 0 : R & \xleftarrow{\quad} & R : 0 \\ & |y| & \\ & 1 & 1 \\ 1 : R & \xleftarrow{\quad} & R : 1 \\ & \{1\} |y| & \end{array}$$

ChainComplexMap

Input

$$\begin{array}{l} Kxy = \text{cone}(\text{MapKxKy}) \\ Kxy\_0 \\ Kxy\_1 \\ Kxy\_2 \\ Kxy\_dd \\ HH\ Kxy \end{array}$$

Now, let us so, now, this extend is a function which tries to extend a map ah, a matrix as a map of complexes. So, we want a map from  $Kx \otimes R^{-1} \rightarrow Kx$  multiplication by  $y$  that is what this one does So, now, it is a map of complexes in both factors its multiplication by  $y$  and then,

we ask Macaulay to construct its cone and we call the cone Kxy.

(Refer Slide Time: 32:57)

Input

```

Kxy = cone(MapKxKy)
Kxy_0
Kxy_1
Kxy_2
Kxy.dd
HH Kxy
prune oo
        
```

Output

```

1      2      1
R <-- R <-- R
0      1      2
ChainComplex
1
R
R-module, free
        
```

So, if you ask for Kxy now, its cone of 2 elements and you know one can inductively prove that the matrices in the I mean the modulus in the Koszul complex are free modules. 0th module is this 0, first module is 2 copies remember it is in the; it is in the diagonal there are 2 elements and after that both complexes end. So, there is only 1 in the next stage.

(Refer Slide Time: 33:23)

```

HH Kxy
prune oo
        
```

Output

```

1      2      1
R <-- R <-- R
0      1      2
ChainComplex
1
R
R-module, free
2
R
R-module, free, degrees {2:1}
1
R
        
```

And so, here, it is degree 0, the first module is 2 : 1 which means 2 generators of degree 1.

(Refer Slide Time: 33:35)

```
R-module, free, degrees {2}
0 : R <----- R : 1
    | x y |

    2          1
1 : R <----- R : 2
    {1} | y |
    {1} | -x |

ChainComplexMap

0 : cokernel | x y |

1 : subquotient ({1} | -y |, {1} | y |)
    {1} | x | {1} | -x |
```

And the second one, the final one is degree 2 so, that is those are the commands and then, we ask for the maps and these are the maps. So, when we work out the chain complex maps using the mapping cone, one can see that these are the maps. We can ask so, we here we also ask for its homology and prune is to minimize the number of generators.

(Refer Slide Time: 33:57)

```
2          1
1 : R <----- R : 2
    {1} | y |
    {1} | -x |

ChainComplexMap

0 : cokernel | x y |

1 : subquotient ({1} | -y |, {1} | y |)
    {1} | x | {1} | -x |

2 : image 0

GradedModule

0 : cokernel | y x |

1 : 0

2 : 0
```

And so, when you ask for its homology, it said its a co kernel  $|x y|$ , the middle one it said it is a sub quotient of this so, in other words, it is the it is a submodule generated by this modulo the image of this one and when you ask for it to prune, this this the first homology is 0, so,

one gets only 1 element and let us just quickly look at it for 3 elements.

(Refer Slide Time: 34:23)

**3 3 elements**

Input

```
Kxy1 = Kxy**R^{-1}
Kxy1.dd
```

Output

```

1      2      1
R <-- R <-- R
⊕
0      1      2

ChainComplex

1      2
0 : R <----- R : 1
      {1} | x y |

5
```

So, now, we do the same thing we take the complex Kxy and then, shift its degrees by 1 ok. So, all that we have done is just shift its degrees.

(Refer Slide Time: 34:33)

Input

```
extend (Kxy, Kxy1, matrix{{z}})
Kxyz = cone oo
Kxyz.dd
```

Output

```

1      1
0 : R <----- R : 0
      | z |

2      2
1 : R <----- R : 1
      {1} | z 0 |
      {1} | 0 z |

1      1
2 : R <----- R : 2
      {2} | z |

⊕
ChainComplexMap

1      3      3      1
R <-- R <-- R <-- R
```

Now, take so, the new complex is called Kxy1. So, get a map from Kxy1 to Kxy multiplication by z, then ask for its cone and look at its look so, this is the; this is the extension. So, this is shifted and everywhere its multiplication by z. So, here there are two factors. So, it is a 2 by 2 matrix and then, we ask for its cone. So, we get something like this

with 1, 3, 3, 1.

(Refer Slide Time: 35:05)

```

1      3      3      1
R <-- R <-- R <-- R

0      1      2      3

ChainComplex

1      3
0 : R <----- R : 1
      | x y z |

3      3
1 : R <----- R : 2
      {1} | y z 0 |
      {1} | -x 0 z |
      {1} | 0 -x -y |

3      1
2 : R <----- R : 3
      0

```

6

And we ask for its maps this is what we get. If you did this by hand, we would get I mean depending on the sign conventions, we might get a slightly different with different signs, but it would be isomorphic to this.

(Refer Slide Time: 35:17)

Input

```

koszul map(R^{0}, R^{\{3:-1\}}, \{x,y,z\})
oo.dd

```

Output

```

1      3      3      1
R <-- R <-- R <-- R

0      1      2      3

ChainComplex

1      3
0 : R <----- R : 1
      | x y z |

3      3
1 : R <----- R : 2
      {1} | \otimes y -z 0 |
      {1} | x 0 -z |
      {1} | 0 x y |

```

And so, we can ask. So, this we what we constructed by cone, we could have just asked Macaulay to construct the Koszul complex from the map to so, the generator here is in degree 0, 3 generators of degree -1 and they get mapped to x times this, y times this and z times this

we ask for its chain complex. So, this this sign I mean it is a convention of how one is taking the tensor product. So, this matrix is almost the same as this matrix except for some changes in sign, but that is.

(Refer Slide Time: 35:53)

```

n  ^-- n  ^-- n  ^-- n
0   1    2    3

ChainComplex

      1          3
0 : R <----- R : 1
      | x y z |

      3          3
1 : R <----- R : 2
      {1} | -y -z 0 |
          {1} | x  0 -z |
          {1} | 0  x y  |

      3          1
2 : R <----- R : 3
          {2} | z  |
          {2} | -y |
          {2} | x  | 0

ChainComplexMap

```

And then finally, one gets this. Yeah, that is the end of this lecture.
