Connecting the Jordan Measure with the Riemann integral – Part 2

(Refer Slide Time: 00:22)

Thm: If $E \subseteq \mathbb{R}$ is a bounded subset, then E is Jordan measurable if and only if $\chi_E(x) = \begin{cases} 1 & \text{if } x \in E \\ 0 & \text{otherwise} \end{cases}$ is Riemann integrable in the sense that $\int_a^b \chi_E(x) dx$ exists when $E \subseteq [a, b]$.

In this case we have

$$m(E) = \int_a^b \chi_E(x) dx$$

Pf: We will show that $m_*(E) = \int_a^b \chi_E(x) dx$ and $m^*(E) = \int_a^b \chi_E(x) dx$

Now we return to the theorem that we want to prove which is stated here so we consider a bounded subset of \mathbb{R} and the statement this theorem state that E this bounded subset E is Jordan measurable. If and only if the indicate function for this set E χ_E is Riemann integreable in the sense this integral exist and here I have added another statement which then identifies the Jordan measure with this integral from a to b of χ_E dx .

So, not only that Jordan measurability of E implies the Riemann integrability of the indicative function and vice versa. But the Jordan measure is actually exactly the value of integral of the indicative function. So let us see a proof here and we will show that the inner Jordan measure of E is precisely equal to the lower Darboux integral of χ_E . And the outer Jordan measure of E is precisely the upper Darboux integral of χ_E .

So I will just prove the statement for the inner Jordan measure and the proof for the outer Jordan measure is very similar.

(Refer Slide Time: 02:10)

Now let's show that given $\epsilon > 0$,

$$m_j(E) \leq \int_a^b \chi_E(x) dx + \epsilon.$$

Choose an elementary set $A \subseteq E$ s.t.

$$m_j(E) \leq m(A) + \epsilon$$

if $E \subseteq [a, b]$, then we can partition $[a, b]$ as follows:
 Choose disjoint intervals I_k s.t. $A = \bigcup_{k=1}^n I_k$
 and $\{J_\ell\}_\ell^m$ be an arbitrary partition of $(a, b) \setminus A$.
 Then χ_A is a piecewise constant fn. s.t.
 $\chi_A = 1$ on each I_k and $\chi_A = 0$ on each J_ℓ .
 and $\chi_A \leq \chi_E$.

So I will leave that as an exercise so first let us show that given epsilon greater than 0 the inner Jordan measure of E is less than or equal to the lower Darboux integral + epsilon. So since epsilon is arbitrary then it would imply that the inner Jordan measure is less than or equal to the lower Darboux integral. So to show this chose an elementary set A of E such that the inner Jordan measure is less than or equal to m of A + epsilon.

Now if E is the subset of this interval a, b then we can partition this interval a, b as follows so first choose intervals we can in fact choose a disjoint intervals I_k such that A is the union of I_k $k = 1$ to, n let us say. And we can and let J_ℓ from 1 to n be an arbitrary partition of the set a, b - A. So we take the partition inside A or disjoint it intervals I_k which is used in the disjoint union expression for the elementary set A and we can take an arbitrary partition for a, b - A.

Then the indicative function of A is a piecewise constant function such that χ_A equals 1 on each I_k and χ_A equals to 0 on each J_ℓ . So this is straight forward from the definition of the indicative function because if a point x belongs to one of this I_k 's where it belongs to A and we will have the value 1. And if it is outside A then will have the value 0 so this is still a piecewise constant function and χ_A is less than or equal to χ_E . We have a point wise inequality of functions χ_A is less than or equal to χ_E .

(Refer Slide Time: 05:58)

$$\begin{aligned}
\text{Therefore } m(A) &= \sum_{k=1}^n m(I_k) \\
&= \sum_{k=1}^n 1 \cdot m(I_k) + \sum_{k=1}^n 0 \cdot m(J_k) \\
&= \int_a^b \chi_A(x) dx \\
m(A) &\leq \int_a^b \chi_E(x) dx \quad (\text{since } \chi_A(x) \leq \chi_E(x) \\
&\quad \forall x \in [a, b]) \\
m_J(E) &\leq m(A) + \epsilon \leq \int_a^b \chi_E(x) dx + \epsilon \\
\text{Since } \epsilon > 0 \text{ is arb. } &\Rightarrow m_J(E) \leq \int_a^b \chi_E(x) dx.
\end{aligned}$$

So therefore m of A which is the definition of sum of $m I_k$ $k = 1$ to, n this can be written as $k = 1$ to, n 1 times $n I_k + L = 1$ to, n 0 times $n J_L$. So this is the piecewise constant Riemann Darboux integral for the indicative function of p which is the p square constant function. So we have indicated that the piecewise constant in Riemann Darboux integral for $K_i A$ is nothing but the elementary measure of the elementary set A .

So therefore this is m of A is less than or equal to the lower Darboux integral from a to b of $K_i \chi_A(x) dx$. Since we also have the $K_i \chi_A(x)$ is less than or equal to $K_i \chi_E(x)$ for all x in this interval a, b . So we have that the inner Jordan measure of E which was less than or equal to $m(A) + \epsilon$ this is less than or equal to again the lower Darboux integral $+ \epsilon$. And since ϵ is arbitrary this implies that the lower the inner Jordan measure is less or equal to the lower Darboux integral of $K_i E$.

(Refer Slide Time: 08:12)

To show: $\int_a^b \chi_E(x) dx \leq m_*(E)$.

$$\int_a^b \chi_E(x) dx = \sup_{\substack{g \leq \chi_E \\ g \text{ piecewise} \\ \text{const.}}} \int_a^b g(x) dx$$

Given g a piecewise const fn. st. $g \leq \chi_E$, choose a partition $\{I_k\}_{k=1}^n$

of $[a, b]$ s.t. $g = c_k$ on I_k .

$$\int_a^b g(x) dx = \sum_{k=1}^n c_k m(I_k)$$

Note that each $c_k \leq 1$. (since $g \leq \chi_E$)
Some of the c_k 's may be negative.

Now we have to prove the reverse inequality to show that the lower Darboux integral is less than or equal to the inner Jordan measure of E . So to show this remember that by definition we have this is the supremum of piece wise constant functions g which are point less than or equal to f , and you take the piece wise constant Riemann Darboux integral for the function g now what we can do here is the following.

So if J_k so here I am using the fact that if given g a piece wise constant function such that g is less than or equal to. So this is supremum over K_i g less than or equal to K_i e if you take any piece wise constant function g such that g is less than or equal to K_i e because g is piece wise constant we can choose a partition I_k $k = 1$ to, n again say of this interval a, b such that $g = c_k$ on I_k .

And in fact the piecewise constant Riemann Darboux integral for g is then $c_k m(I_k)$ $k = 1$ to, n now in this sum we note that each c_k must be less than or equal to 1. Since g is less than or equal to K_i E and the indicator function takes the value at most 1. So each c_k is less than or equal to 1 also some of this c_k 's may be negative. So sum of this c_k 's may be negative so I will only consider those c_k 's which are positive in this sum and then bound it above by 1.

(Refer Slide Time: 11:10)

if I' is the set of indices in $\{1, 2, \dots, n\}$ s.t.
 $1 \geq c_{i'} > 0 \quad \forall i' \in I'$

$$\int_a^b f(x) dx = \sum_{k=1}^n c_k m(I_k) \leq \sum_{i' \in I'} m(I_{i'}) = m\left(\bigcup_{i' \in I'} I_{i'}\right)$$

\therefore the elementary set $\bigcup_{i' \in I'} I_{i'} \subseteq E$
 (since $c_{i'} > 0 \quad \forall i' \in I'$).

we can write:

$$\int_a^b f(x) dx \leq m\left(\bigcup_{i' \in I'} I_{i'}\right) \leq \underbrace{m_J(E)}_{\text{independent of } g}.$$

$$\int_a^b \chi_E dx = \sup_{\mathcal{R} \leq \mathcal{R}_E} \int_a^b f(x) dx \leq m_J(E).$$

So therefore if c_k is positive so let me write the set of indices if J prime is the set of indices or let us say I prime is the set of indices in $1, 2$ up to n such that c_i prime is greater than 0 for all i prime in this set i prime Which means that we are only choosing those indices for which this constant value for g is positive. So then the Riemann Darboux integral of g_x which is equal to the sum $k = 1$ to n and c_k measure of I_k this is then less than or equal to the sum over I prime m of I_i prime.

So we are only taking those indices for which c_i prime is greater than 0 but we already know that c_i prime must be bounded above by 1 . And since we have discarded the negative values this can be bounded above in the sum c_k and $m I_k$ can be bounded above by this new sum over the indices for which C this value c_k are positive strictly positive. So now therefore they elementary set the union I_i prime belongs to the I prime this is an elementary sets that sits inside E that must sit inside E because c_i prime is greater than 0 .

And therefore so this is because since c_i prime is greater than 0 for all i prime in i prime because otherwise this point wise inequality that we had for g and K_i will not hold. So we have produce an elementary set with sits inside E and the Riemann Darboux integral of g is bounded above by the elementary measure which is the elementary measure of the union i prime of I_i prime. So this is our required elementary set that we needed which sits inside E

And so we can write that the piecewise constant Riemann Darboux integral for g is less than or equal to the measure of the elementary set which is the union of I_i primes over i prime and this is less than or equal to the inner measure by the definition of the inner Jordan measure. So for each g for any g in fact which is piecewise constant on a, b we have this inequality which bounds the Riemann Darboux integral of the piecewise constant function g by the inner Jordan measure of g .

Now the right hand side of this inequality this is independent of g so therefore we can take the supremum over g less than equal to $K_i E$ g piecewise constant and take the values of the Riemann Darboux integral of this piecewise constant functions. And this supremum will also be bounded above by the inner Jordan measure of E and this is nothing but on the left hand side this is nothing but by the definition of the lower Darboux integral this is the lower Darboux integral of $K_i E$. So we have the reverse inequality that we want to it.

(Refer Slide Time: 16:02)

Generalization to \mathbb{R}^d : if $f: B \rightarrow \mathbb{R}$ is a bdd fn.

closed box

then one can define the upper & lower Darboux integrals in the same way as before, replacing intervals with boxes in \mathbb{R}^d .

$$\int_B f(x) dx = \sup_{\substack{g \leq f \\ g \text{ piecewise const.}}} \int_B g(x) dx \rightarrow \text{Lower Darboux}$$

Piecewise const. fn. g on $B \Leftrightarrow \exists$ a partition of B into boxes $\{B_i\}_{i=1}^n$ s.t. $g = c_i$ on B_i .

$$\int_B g(x) dx := \sum_{i=1}^n c_i m(B_i)$$

Now we come to the generalization of the previous result to any \mathbb{R}^d we have seen it for dimension 1 and we can easily generalize these results to arbitrary dimension. So for that if f is function from a box in \mathbb{R}^d so this is the box closed box in \mathbb{R}^d let us say. And it is supposed to be bounded function then one can define the upper and lower Darboux integrals in the same way as before replacing intervals with boxes in \mathbb{R}^d .

So for example the lower Darboux integral over this box B of this function f is equal to the supremum of over functions g which are point wise bounded by f g piecewise constant and we

can take the piecewise constant Riemann Darboux integral of this piecewise constant function g over this box B . So here piecewise constant function g on b is the same as saying that they exist the partition of B into boxes B_i $i = 1$ to, n such that g takes the value C_i on B_i .

So it is constant on each B_i so we have replaced intervals with boxes and the rest of the definition remains the same and in this case the piecewise constant Riemann Darboux integral is by definition the sum $C_i m$ of B_i $i = 1$ to, n . So we can also define in the same way the upper Darboux integral so this is the lower Darboux integral.

(Refer Slide Time: 19:15)

$$\int_B f(x) dx = \inf_{\substack{f \leq h \\ h \text{ piecewise} \\ \text{const. on } B}} \int_B h(x) dx.$$

Thm: If $E \subseteq \mathbb{R}^d$ is a bdd. subset, then E is Jordan measurable $\Leftrightarrow \chi_E$ is Riemann-Darboux integrable

\Leftrightarrow If $E \subseteq B$ then $\int_B \chi_E(x) dx$ exists

and in this case

$$m(E) = \int_B \chi_E(x) dx.$$

And we can also define the upper Darboux integral of f over this box b which is the infimum of, f less than or equal to h piecewise constant on B and you can take the piecewise constant Riemann Darboux integral of the function h . So with these notions we can write the theorem which is the generalization of the previous theorem for arbitrary dimensions. If E is a subset of the bounded subset of \mathbb{R}^d then E is Jordan measurable.

If and only if χ_E is Riemann Darboux integral which is the same as saying that if E is sitting inside a box b then the Riemann Darboux integral of χ_E over this box B exist. And in this case the measure the Jordan measure of E is precisely this integral of the indicative function over B . So this is the straight forward generalization using the same proof basically we can rewrite the proof for arbitrary dimensions and it will work fine.

(Refer Slide Time: 21:18)

Corollary: If $f: [a, b] \rightarrow \mathbb{R}^+$ is a bounded fn., then f is Riemann-Darboux integrable if and only if the subset $E_f \subseteq \mathbb{R}^2$ given by

$$E_f = \left\{ (x, t) \in \mathbb{R}^2 \mid x \in [a, b], 0 \leq t \leq f(x) \right\}$$

is Jordan measurable in \mathbb{R}^2 . In this case

$$m(E_f) = \int_a^b f(x) dx$$

Pf: Carefully repeat the proof given for the statement -
 $E \subseteq [a, b] \times \mathbb{R}^+$ is Jordan measurable $\Leftrightarrow \int_a^b \chi_E(x) dx$ exists.

So as a corollary as an application of this theorem or corollary we state the following result that if f is the function is a bounded function over an interval a, b then f is a Riemann darboux integrable. If and only if, the subset E_f of \mathbb{R}^2 given by this is similar to the region and the graph actually exactly the region and the graph which; you have seen before. Such that x belongs to a, b and 0 less than equal to t less than or equal to fx so here let me take only for positive real's \mathbb{R}^+ .

So f only takes non negative values so this subset is Jordan measureable in \mathbb{R}^2 in this case the Jordan measure of E_f is exactly the Riemann integral of fx . So I will leave the proof as an exercise because it is essentially a repetition of the proof that was given earlier for the last theorem which stated that when he is Jordan measureable. If and only if the indicative function is Riemann Darboux integrable.

So I will just write that we have to carefully repeat the proof given for the statement E is the subset of a, b is Jordan measureable this was the statement of the theorem that was given before. If and only if the Riemann integral of the indicative function exist, so one has to carefully repeat it because there are some differences between that proof and this proof nevertheless the idea of the proof is entirely the same and one can replace the we can make the necessary replacement to get the proof for this case as well.
