Lecture – 21
Finite Additivity of Outer measure on Separated Sets, Outer Regularity – Part 1

(Refer Slide Time: 00:14)

More Properties of Lebesgue Outer Measure:

1. Finite additivity for separated sets.
2. Outer regularity.

So, let us continue studying some more properties of the Lebesgue outer measure. In this lecture, we will look at 2 more properties, the first one is called finite additivity for separated sets, and the second one is called outer regularity.

(Refer Slide Time: 00:34)

Remark: Due to Banach-Tarski paradox, we cannot expect finite additivity property to hold for arbitrary disjoint subsets E, F of \mathbb{R}^d , i.e.

$$m^*(E \cup F) \neq m^*(E) + m^*(F)$$

\Rightarrow We must restrict our attention to smaller classes of disjoint pairs of sets E & F .

Defn: (Separated sets): Two subsets $E, F \subseteq \mathbb{R}^d$ are called separated if $d(E, F) > 0$, i.e. the quantity $\inf \{ \|x - y\| : x \in E, y \in F \} > 0$.

$\Rightarrow E \cap F = \emptyset$.

So, let me start with the remark is that, due to the banach tarski paradox that we have seen before due to the banach tarski paradox, we cannot expect finite additivity property to hold for arbitrary subsets $E F$ of \mathbb{R}^d this is to say that the outer measures of E union. So, arbitrary

disjoint subsets of \mathbb{R}^d which is to say that the outer measure of E union F may not be equal to the outer measure of E plus the outer measure of F .

So, we must this implies that we must restrict our retention to smaller classes of rather than taking arbitrary sets E and F we have to restrict our what kind of sets we allow for considering finite additivity. So, 2 smaller classes of disjoint pairs of sets E and F . So, one such restriction is given by the so called separated sets. So, 2 sets 2 subsets E and F of \mathbb{R}^d are called separated if the distance between E and F is strictly greater than 0.

This is the quantity given by the infimum of the Euclidean distance between 2 points such that X and Y such that x is in E and y is in F . So, this infimum is strictly greater than 0. So, in this case we call E and F separated. So, of course, if this happens one can also show that this implies that E and F are disjoint because, if E and F have a common point then the Euclidean distance between that point with itself is going to be 0. So, the infimum is will be 0. So, separated implies disjoint.

(Refer Slide Time: 03:54)

Lemma: (Finite additivity property for separated sets) Let $E, F \subseteq \mathbb{R}^d$ be separated sets. Then

$$m^*(E \cup F) = m^*(E) + m^*(F).$$

pf: By sub-additivity

$$m^*(E \cup F) \leq m^*(E) + m^*(F)$$

(Countable sub-additivity \Rightarrow Finite sub-additivity).

To show: $m^*(E) + m^*(F) \leq m^*(E \cup F)$.

If $m^*(E \cup F) = +\infty$, then the inequality holds.

So suppose that $m^*(E \cup F) < \infty$

So, the next lemma establishes finite additivity property for separated sets. So, let E and F the subsets of \mathbb{R}^d which are separated the separated sets. Then, we have the finite additivity property, which is that the outer measure of the union Lebesgue outer measure the union is equal to the sum of the Lebesgue outer measure of E and F . So, let us try to prove this. So, by sub-additivity we have that the measure the outer measure of the union is bounded above by the sum of the Lebesgue outer measure of E and F .

So, we have seen countable sub additivity. So, in this case we only have finite only 2 sets, but we can add infinitely many countable many empty sets and then the measures all for all the rest of the sets will be 0 and we will get this inequality. So, countable sub-additivity implies finite sub-additivity. So, it is enough to show the reverse inequality, which is that $m^* E + m^* F \leq m^* (E \cup F)$. So, again, notice that if $m^* E \cup F$ is plus infinity, then the inequality is stable inequality holds. And so, suppose that $m^* E \cup F$ is finite.

(Refer Slide Time: 06:34)

Given $\epsilon > 0$, there exists a collection of boxes $\{B_i\}_{i=1}^{\infty}$ such that
 $E \cup F \subseteq \bigcup_{i=1}^{\infty} B_i$ and
 $\sum_{i=1}^{\infty} m(B_i) \leq m^*(E \cup F) + \epsilon.$

Suppose that we have sub-collections $\{B'_l\}_{l=1}^{\infty}$ and $\{B''_j\}_{j=1}^{\infty}$
of the collection $\{B_i\}_{i=1}^{\infty}$ such that $E \subseteq \bigcup_{l=1}^{\infty} B'_l$
and $F \subseteq \bigcup_{j=1}^{\infty} B''_j$, and none of the B'_l 's intersect F and
none of the B''_j 's intersect E.
 $\Rightarrow m^*(E) + m^*(F) \leq \sum_{l=1}^{\infty} m(B'_l) + \sum_{j=1}^{\infty} m(B''_j).$

So, now, I am going to again use the infimum definition of the Lebesgue outer measure. So, there exists. So, given epsilon greater than 0, there exists a collection of boxes B_i $i = 1$ to infinity such that E is covered by the union of these B_i $i = 1$ to infinity and the sum $i = 1$ to infinity of the measures of these B_i is bounded above by $m^* E + \epsilon$. So, now, suppose that B_i suppose that we have sub-collections B_l prime $l = 1$ to infinity and B_j double prime.

So, to distinguish the indices, I will write here l for the first one and j for the second one, $j = 1$ to infinity certainly such that. So, these are sub-collections of the original collection of the collection B_i $i = 1$ to infinity. So, each of these be B_l prime and B_j double prime are one of these B_i s. So, such that E is covered by, I have to cover $E \cup F$ by this rather than just E , I am going to cover $E \cup F$ by the whole collection B_i and so, now, I am dividing the collection B_i into 2 sub-collections, one that covers E .

So, B_l for $l = 1$ to infinity and F is covered by B_j for $j = 1$ to infinity. We also suppose that none of the B_l intersect F and none of the B_j intersect E . So, then these 2 collections are separate there is no overlap between them. So, this implies that $m^*(E) + m^*(F)$ is bounded above by the sum $l = 1$ to infinity $m(B_l)$ and then $j = 1$ to infinity $m(B_j)$. But if because of this assumption that we have that none of the B_l intersect F and none of the B_j intersect E .

(Refer Slide Time: 10:36)

Due to our assumptions on $\{B_l\}_{l=1}^{\infty}$ & $\{B_j\}_{j=1}^{\infty}$, we have

$$\sum_{i=1}^{\infty} m(B_i) = \sum_{l=1}^{\infty} m(B_l) + \sum_{j=1}^{\infty} m(B_j)$$

$\Rightarrow m^*(E) + m^*(F) \leq \sum_{i=1}^{\infty} m(B_i) \leq m^*(E \cup F) + \epsilon$

and since $\epsilon > 0$ was arb., so,

$$m^*(E) + m^*(F) \leq m^*(E \cup F)$$

But in general the assumption may not be true that $B_l \cap F = \emptyset \forall l \geq 1$, $B_j \cap E = \emptyset \forall j \geq 1$ *violates the assumption.*

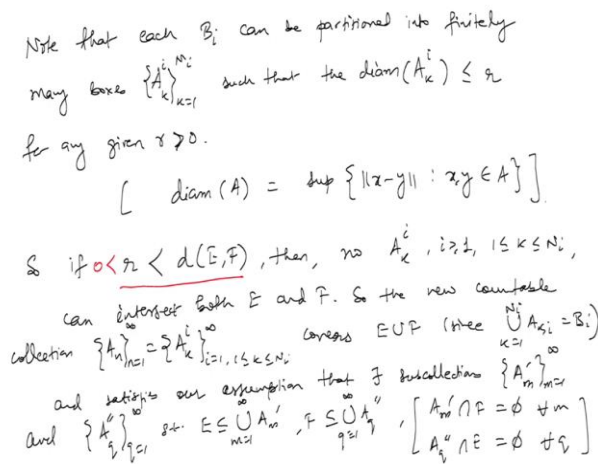

This implies the due to our assumptions on these collections B_l for $l = 1$ to infinity and B_j for $j = 1$ to infinity, we have that the sum $i = 1$ to infinity of the measures B_i for $i = 1$ to infinity $m(B_i)$ is bounded above by $m^*(E \cup F) + \epsilon$. So, this is because there is no overlap between these 2 collections B_l for $l = 1$ to infinity and B_j for $j = 1$ to infinity. So, this implies that the measure of outer measure of E plus the outer measure of F is bounded above by this sum $m(B_i)$.

But this was chosen such that this is less than or equal to $m^*(E \cup F) + \epsilon$ and since, again ϵ is arbitrary was arbitrary. So, we get the required inequality $m^*(E) + m^*(F) \leq m^*(E \cup F)$. But now, in general the assumption may not be true that none of the so, let me write it in symbols $B_l \cap F = \emptyset$ for all $l \geq 1$ and $B_j \cap E = \emptyset$ for all $j \geq 1$.

So, this may not be true because, for example, if you have 2 sets E and F . So, there could be one box B_j or B_i which intersects both and so, our assumption will be invalid, because this set will neither belong to any of the B_l for $l = 1$ to infinity nor will it belong to any of the B_j for $j = 1$ to infinity.

primes. So, this will violate our assumption. So, this set violates this assumption. So, what we have to do is to use the fact that these 2 sets are separated and we have to break these big boxes B_i into smaller chunks, so, that none of the smaller bits overlap both intersect both E and F .

(Refer Slide Time: 14:04)

Note that each B_i can be partitioned into finitely many boxes $\{A_k^i\}_{k=1}^{m_i}$ such that the $\text{diam}(A_k^i) \leq r$ for any given $r > 0$.

$$\left[\text{diam}(A) = \sup \{ \|x-y\| : x, y \in A \} \right]$$

So if $0 < r < d(E, F)$, then, no $A_k^i, i \geq 1, 1 \leq k \leq m_i$, can intersect both E and F . So the new countable collection $\{A_k^i\}_{i=1, 1 \leq k \leq m_i}^{\infty}$ covers $E \cup F$ (since $\bigcup_{k=1}^{m_i} A_k^i = B_i$) and satisfies our assumption that \exists sub-collections $\{A_k^i\}_{m_i=1}^{\infty}$ and $\{A_k^j\}_{j=1}^{\infty}$ s.t. $E \subseteq \bigcup_{m_i=1}^{\infty} A_k^i, F \subseteq \bigcup_{j=1}^{\infty} A_k^j, [A_k^i \cap F = \emptyset \forall i, A_k^j \cap E = \emptyset \forall j]$

So, note that each B_i can be partitioned into finitely many boxes. Now, let me give it a different name $A_k, k = 1$ to m_i , so, for each i , we will have a partitioning of each box B_i into finitely many boxes such that the diameter of each A_k^i is less than or equal to r for any given r greater than 0. So, here the diameter of a set A this is the supremum of the Euclidean distance between any 2 points of A .

So, we can restrict the diameter of the partition boxes, the boxes used in the partitioning of each B_i says that the diameter is bounded above by any given positive number r . So, if r is taken to be strictly less than the distance between E and F then no A_k^i for i greater than or equal to 1 and $1 \leq k \leq m_i$ can intersect both E and F . So, that so, the new countable collection of boxes $A_k^i, i = 1$ to infinity $k = 1$ to m_i .

So, this collection covers $E \cup F$ because the union when you take the union of these A_k^i over k this is precisely B_i because this is a partitioning of this box B_i and this collection satisfies our assumption that there exists sub-collections A . So, rather than taking 2 indices, I can rewrite it re-index it to write it as a collection it $A_n, n = 1$ to infinity. So, now, we can break these this collection A_n s into 2 sub-collections and A_m prime.

And then let us say $A \cap B$ double prime $q = 1$ to infinity such that E is covered by the first collection and F is covered by the second collection and it also satisfies that $A \cap B$ prime intersection F is empty for all M and $A \cap B$ double prime intersection E is empty for all q . So, this assumption will be satisfied once you subdivide each box B_i into smaller boxes with diameter bounded above by the distance $d(E, F)$. So, note that this is a positive number. So, r can be chosen here greater than 0. So, this takes care of r assumption that we had before and in general case also we can reduce to that case. So, this proves the lemma.

(Refer Slide Time: 19:27)

Lemma [Outer regularity]: Let $E \subseteq \mathbb{R}^d$. Then

$$m^*(E) = \inf_{\substack{E \subseteq U \\ U \text{ open}}} m^*(U)$$

Pf: First note that $m^*(E) \leq m^*(U)$ for any set $U \supseteq E$. So

$$m^*(E) \leq \inf_{\substack{E \subseteq U \\ U \text{ open}}} m^*(U). \quad [\text{Monotonicity}]$$

To show: $\inf_{\substack{E \subseteq U \\ U \text{ open}}} m^*(U) \leq m^*(E)$.

We will show that given $\epsilon > 0$ we have $\inf_{\substack{E \subseteq U \\ U \text{ open}}} m^*(U) \leq m^*(E) + \epsilon$.

The next lemma is called outer regularity and this says that the outer measure so, let E be a subset of \mathbb{R}^d then we have a formula for the outer measure given by the infimum of the outer measures of sets u that are super sets of E such that each of these u 's are open. So, this is called outer regularity property for the Lebesgue outer measure and this is one of the most important properties and we will see that this property also can be it can also appear in the abstract measures based context.

So, let us try to prove this. So, first note that note that $m^*(E)$ is less than or equal to $m^*(u)$ for any open set u that contains E . So, we can take an infimum on the right hand side and we will get $m^*(E)$ is less than or equal to the infimum of these sets u each of these u 's are open and E is contained in each of these open sets u . So, this is obvious from the monotonicity property. Now, so, it is at suffices to show the reverse inequality which is that infimum over open sets of $m^*(u)$ less than or equal to $m^*(E)$.

So, in particular what we will do is we will show that given epsilon greater than 0, we have infinite infimum of these sets $m^* u$ less than or equal to $m^* E + \epsilon$. So, again we use the epsilon trick and we will try to show this inequality here.

(Refer Slide Time: 22:22)

First note that if $m^*(E) = +\infty$ then the inequality holds
 Suppose that $m^*(E) < \infty \Rightarrow \exists$ a collection of boxes $\{B_i\}_{i=1}^{\infty}$
 st. $E \subseteq \bigcup_{i=1}^{\infty} B_i$ and $\sum_{i=1}^{\infty} m(B_i) \leq m^*(E) + \frac{\epsilon}{2}$ *may not be open.*
 For each i , choose an open box B_i' such that $B_i \subseteq B_i'$
 and $m(B_i') \leq m(B_i) + \frac{\epsilon}{2^{i+1}}$
 $\Rightarrow \sum_{i=1}^{\infty} m(B_i') \leq \sum_{i=1}^{\infty} m(B_i) + \frac{\epsilon}{2} \leq m^*(E) + \epsilon$
 $\Rightarrow E \subseteq \bigcup_{i=1}^{\infty} B_i'$ an open set and $m(\bigcup_{i=1}^{\infty} B_i') \leq \sum_{i=1}^{\infty} m(B_i') \leq m^*(E) + \epsilon$.

So, to show this first note that if $m^* E$ is infinite, then the inequality holds trivially equality holds. So, suppose that $m^* E$ is finite. So, in this case this implies that there exists a collection of boxes B_i $i = 1$ to infinity such that E is contained inside this union of the B_i 's and the sum are equal to 1 to infinity and B_i less than or equal to $m^* e + \epsilon$. So, let me take epsilon by 2 here. So, now, these B_i 's that we have taken these may not be open, but, we can enlarge each of these B_i 's as we have done in the last lecture.

We can enlarge these B_i 's such that they become open but still we can have control over the volume of the union. So, for each i choose an open box B_i' such that the measure of B_i' is first of all that B_i 's contained in B_i' and the measure of B_i' is less than or equal to the measure of $B_i + \epsilon / 2^{i+1}$. So, this implies that the sum from $i = 1$ to infinity m of B_i' is less than or equal to the sum $i = 1$ to infinity $m B_i$ and then you will have an extra term of $\epsilon / 2$ but this is less than or equal to $m^* E + \epsilon / 2$.

So, these $2 \epsilon / 2$ s can be written as ϵ . So, we have produced E is covered by these boxes B_i' $i = 1$ to infinity and so, this is an open set, this is an open set and the measures of the union of $i = 1$ to infinity B_i' less than or equal to this sum $i = 1$ to infinity and B_i' which is bounded above by $m^* E + \epsilon$. So, we have

produced an open set such that it is bounded above by $m \star E + \epsilon$. Therefore, when we take the infimum over all open sets, then it is going to be less than this quantity.
