**Equivalent Criteria for Lebesgue Measurability of a Subset - Part I**

(Refer Slide Time: 00:15)

Measure Theory - Lecture 15

Equivalent Conditions for Lebesgue Measurability:

Thm: Let  $E \subseteq \mathbb{R}^d$  be an arbitrary set. Then the following are equivalent:

- (i)  $E$  is Lebesgue measurable, i.e. given  $\epsilon > 0$ ,  $\exists$  an open set  $U \supseteq E$  such that  $m^*(U \setminus E) \leq \epsilon$ .
- (ii) [Almost-open] Given  $\epsilon > 0$ ,  $\exists$  an open set  $U$  such that  $m^*(U \Delta E) \leq \epsilon$ . [ $E$  may not be a subset of  $U$ ].
- (iii) [Inner approximation by closed sets] Given  $\epsilon > 0$ ,  $\exists$  a closed set  $F \subseteq E$  such that  $m^*(E \setminus F) \leq \epsilon$ .

In the last lecture, we have seen that the class of Lebesgue measurable sets is a, is very big and in particular it is closed under taking complements, taking countable unions and taking countable intersections. So, in this lecture, we will look at some equivalent criteria for Lebesgue measurability we have defined, we have given 1 definition of Lebesgue measurability and we will see that there are plenty of other equivalent criteria that one can write to for the definition of Lebesgue measurable sets.

So, I have stated this as a theorem let  $E$  be an arbitrary subset of  $\mathbb{R}^d$ , an arbitrary set, then the following are equivalent. So, the first is  $E$  is Lebesgue measurable of course, we want to give equivalent conditions for Lebesgue measurability. So, the first one is basically just the definition of Lebesgue measurability, this is 1, that exists given epsilon greater than 0 there exists.

So, let me fix given any epsilon greater than 0 there exists an open set  $u$  containing  $E$  such that the outer measure of the complement  $u$  set complement  $u - E$  is equal to is less than or equal to epsilon. The second one is it can be termed as almost open criteria which says that given epsilon greater than 0, there exists an open set  $u$  now,  $E$  may not necessarily be

contained in  $u$ , but nevertheless we have that the rather than the set difference, we will take the symmetric difference  $u$  symmetric difference  $E$  is less than or equal to epsilon.

So, here the difference between 1 is that  $E$  may not be a subset of  $u$ . The third is approximation by closed sets inner approximation by closed sets. So, this criteria says that given epsilon greater than 0, there exists a closed set  $F$  contained in  $E$ , this is an inner approximation. So,  $F$  is contained inside  $E$  such that the outer measure of  $E - F$  is less than or equal to epsilon.

**(Refer Slide Time: 04:04)**

(iii)  $\Rightarrow$  (iv) [Almost closed] Given  $\epsilon > 0$ ,  $\exists$  a closed set  $F_\epsilon$  such that  
trivial  $m^*(F_\epsilon \Delta E) \leq \epsilon$

(iv)  $\Rightarrow$  (v) [Almost measurable] Given  $\epsilon > 0$ ,  $\exists$  a measurable set  
trivial  $U_\epsilon$  such that  $m^*(U_\epsilon \Delta E) \leq \epsilon$

PP: (i)  $\Rightarrow$  (ii) Trivial  
(iii)  $\Rightarrow$  (iv)  $\Rightarrow$  (v) Trivial.  
To show: (ii)  $\Rightarrow$  (iii) & (v)  $\Rightarrow$  (i)

The 4th condition is similar to the almost open condition; this is the almost closed condition. It says that given epsilon greater than 0, there exists a closed set  $F$ . Now,  $F$  need not be contained inside  $E$  that is the only difference between this case and the third case, such that outer measure of  $F$  symmetric difference  $E$  is less than or equal to epsilon and the fifth one, this is almost measurable condition this says that given epsilon greater than 0, there exists a measurable subset.

Measurable set  $E$  epsilon such that the outer measure of let me write it,  $u$  epsilon symmetric difference with  $E$  is less than or equal to epsilon. So, here all these sets this set and this closed set in the last condition all of them depend on epsilon. So, let me put an epsilon everywhere, this is  $u$  epsilon,  $u$  epsilon,  $u$  epsilon,  $F$  epsilon. So, these are 5 equivalent conditions so, we have listed 5 equivalent conditions for the, if you want to test some whether some given set is Lebesgue measurable or not so, let us try to show this so, few of these implications.

We will start with 1 and we will see that few of these implications are quite trivial. For example, 1 implies 2 is trivial, this is trivial, because, if  $E$  is a, if you have an open set  $u$  containing  $E$ , then they that will also satisfy this condition here, because if it satisfies this condition, then this condition is the second condition is trivial similarly, 3 implies 4 is trivial. So, 3 implies 4 this is also trivial and 4 implies 5 is also trivial because, if you can find a closed set, then a closed set is a measurable set.

So, fifth one is automatically satisfied, if 4 is satisfied. So, 1 implies 2 is trivial, so, let me know down these things this remarks. So, 1 implies 2 is trivial then, then we have 3 implies 4 is trivial, 3 implies 4 implies 5 these are also trivial. So, one just to has to show that 2 implies 3 and 5 implies 1 then we will be done.

**(Refer Slide Time: 08:22)**

$(i) \Rightarrow (ii)$ : Let  $\epsilon > 0$ . Note that  $(i) \Rightarrow (ii)$  is easy to show.  $\exists$   $U \supseteq E$  open s.t.  $m^*(U \setminus E) \leq \epsilon \Leftrightarrow E$  is Lebesgue measurable.  $\exists$  an open set  $U$  such that  $m^*(U \setminus E) \leq \epsilon$ .

$(ii) \Rightarrow (i)$ : then since  $E^c$  is Lebesgue measurable.  $\exists$  an open set  $V \supseteq E^c$  such that  $m^*(V \setminus E^c) \leq \epsilon$ .

$(i) \Rightarrow (iii)$ : let  $F = V^c$  then  $F \subseteq E$  and  $F$  is closed.  $m^*(E \setminus F) = m^*(E \cap F^c) = m^*(E \cap V) = m^*(E \cap V) = m^*(V \cap E^c) = m^*(V \setminus E^c) \leq \epsilon$ .

So, let us try to show whether 2 implies 3. So, let epsilon greater than 0 be given. Now, note that 1 implies 3, 3 is quite easy to show, because, if we have an open set  $u$  containing  $E$  such that  $m^* u - E$  is less than or equal to epsilon then since, so, this implies that  $E$  is Lebesgue measurable, then this also implies that  $E$  complement is Lebesgue measurable this we have shown before that if  $E$  is Lebesgue measurable then, so is  $E$  complement.

So, then there exists an open set  $V$  containing  $E$  complement such that,  $m^*$  of  $V - E$  complement is less than or equal to epsilon. Now, we have if we want to prove 3, which is to given a subset a closed subset of  $E$  such that auto measure of  $E - F$  is less than or equal to epsilon, then we can take  $F$  to be the complement of this set  $V$  let  $F$  be  $V$  complement, then

the outer measure of  $E \Delta F$ , is this is equal to  $m^* E \cap F^c$  which is equal to  $m^* E \cap V^c$ .

But this is nothing but  $E \cap V^c$  but we can also write it as  $V \cap E^c$  and this is nothing but  $m^* V \cap E^c$  and this is less than or equal to  $\epsilon$ . So, this from the Lebesgue measurability of the complement, we deduce a set  $F$  lying inside  $E$ . So,  $F$  is lying inside  $E$  and  $F$  is closed such that  $m^* E \Delta F$  is less than or equal to  $\epsilon$ .

So, to 1 implies 3 is easy so, let us show that 2 implies 1 and then that would imply that in turn 2 implies 3. So, we have broken up this into 2. The first one is 1 implies 3 this is easy and we will also prove that 1, 2 implies 1 and so, this will imply that 2 implies 3.

**(Refer Slide Time: 12:25)**

(ii)  $\Rightarrow$  (i): Given  $\epsilon > 0$ ,  $\exists$  an open set  $U$  such that

$$m^*(U \Delta E) \leq \epsilon/4$$

We have to find an open set  $U' \supseteq E$  s.t.

$$m^*(U' \setminus E) \leq \epsilon$$

Note that  $m^*(U \setminus E) \leq m^*(U \Delta E) \leq \epsilon/4$   
 (since  $U \Delta E = (U \setminus E) \cup (E \setminus U)$ )

Similarly,  $m^*(E \setminus U) \leq \epsilon/4$ .

Now, use the outer regularity property:  $\exists$  an open set  $V_1 \supseteq U \setminus E$   
 s.t.  $m^*(V_1) \leq m^*(U \setminus E) + \frac{\epsilon}{8} \leq \frac{\epsilon}{4} + \frac{\epsilon}{8} = \frac{3\epsilon}{8}$

So, let us try to show that 2 implies 1 which means that we are given, so, this is 2 implies 1 given  $\epsilon > 0$  there exists an open set  $u$  such that the outer measure of  $u \Delta E$  is less than or equal to  $\epsilon$ . Now,  $u$  may not contain  $E$  as a subset. So, we have to find an open set  $u'$  that contains  $E$  in this case such that the outer measure of  $u' \setminus E$  is less than or equal to  $\epsilon$ .

So, to produce such an open set  $u'$  we will use what we already know from this inequality. So, let me take  $\epsilon/4$  here and you will see why I am taking  $\epsilon/4$ . So, note first that note that  $m^* u \setminus E$  is less than or equal to  $m^* u \Delta E$  which is less than or equal to  $\epsilon/4$  because, since, the symmetric difference is the

union of  $u - E$  and  $E - u$ . Similarly,  $m^*$  of  $E - u$  is also less than or equal to  $\epsilon / 4$ . So, now, we can use the outer regularity property of the Lebesgue outer measure.

So, this implies that there exists an open set  $V_1$  that contains  $u - E$  such that  $m^*$  of  $V_1$  is less than or equal to  $m^*$  of  $u - E$  plus, I am going to take  $\epsilon / 8$  here. So, that this is bounded above by  $\epsilon / 4 + \epsilon / 8$  and this is equal to  $3\epsilon / 8$ .

**(Refer Slide Time: 15:22)**

Similarly,  $\exists$  an open set  $V_2 \supseteq E - u$  s.t.  
 $m^*(V_2) \leq 3\epsilon / 8$ .  
 Now take  $U' = V_1 \cup V_2 \cup U$ . ( $U'$  is open).  
 and  $U' \supseteq E$ . (Check this).  
Claim:  $m^*(U'|E) \leq \epsilon$ .  
 $m^*(U'|E) \leq m^*((V_1 \cup V_2 \cup U)|E)$   
 $\leq m^*(V_1|E) + m^*(V_2|E) + m^*(U|E)$   
 $\leq m^*(V_1) + m^*(V_2) + m^*(U|E) \leq \frac{3\epsilon}{8} + \frac{3\epsilon}{8} + \frac{\epsilon}{4} = \epsilon$   
 This shows (ii)  $\Rightarrow$  (i).

Similarly, there exists an open set  $V_2$  containing  $E - u$  such that the outer measure of  $V_2$  is less than or equal to  $3\epsilon / 8$ . Now take  $u'$  to be the union  $V_1 \cup V_2 \cup u$ , so it is a union of 3 open sets. So,  $u'$  is open and  $u'$  contains  $E$  as well,  $u'$  contains  $E$ . So check this now, I want to show that  $m^*$  of  $u' - E$ , I am claiming that  $m^*$  of  $u' - E$  is less than or equal to  $\epsilon$  so, let us see why?

So,  $m^*$  of  $u' - E$  because this is less than or equal to  $m^*$  of  $V_1 \cup V_2 \cup u - \epsilon - E$  and this is less than or equal to  $m^*$  of  $V_1 - E + m^*$  of  $V_2 - E + m^*$  of  $u - E$ . But the first 2 terms are bounded above by  $m^*$  of  $V_1 + m^*$  of  $V_2$  and then you have  $m^*$  of  $u - E$  and so, this is less than or equal to  $3\epsilon / 8 + 3\epsilon / 8 + \epsilon / 4$  which is equal to  $\epsilon$ .

So, we have shown that  $u'$  is an open set that contains  $E$  and the outer measures of  $u' - E$  is bounded by  $\epsilon$ . So, this shows that part 2 implies part 1. So, going back to the beginning of the proof, we had 2 things that we needed to show the first one was that 2

implies 3. So, this we did and now, we have to show that 5 implies 1. So, recall that 5 is the almost measurable condition which says that given epsilon greater than 0.

There exists a measurable set  $u$  epsilon such that the symmetric difference of epsilon with  $E$  is less than or equal to epsilon and then we have to produce an open set that contains  $E$  such that then outer measure of that open set minus  $E$  is less than or equal to epsilon. So, this would be 5 implies 1. So, let us try to show that 5 implies 1 for this purpose, we will have to define a couple of new notions.

**(Refer Slide Time: 19:01)**

$(iii) \Rightarrow (iv)$  [Almost closed] Given  $\epsilon > 0, \exists$  a closed set  $F_\epsilon$  such that  
 trivial  $m^*(F_\epsilon \Delta E) \leq \epsilon$

$(iv) \Rightarrow (v)$  [Almost measurable] Given  $\epsilon > 0, \exists$  a measurable set  
 trivial  $U_\epsilon$  such that  
 $m^*(U_\epsilon \Delta E) \leq \epsilon$

pp: (i)  $\Rightarrow$  (ii) Trivial  
 (iii)  $\Rightarrow$  (iv)  $\Rightarrow$  (v) Trivial.

To show: (ii)  $\Rightarrow$  (iii) & (v)  $\Rightarrow$  (i)

So, let me define the notions of limit superior and limit inferior of sets in  $R^d$ . So, let  $A_n, n = 1$  to infinity be a sequence of subsets of  $R^d$  then they may not be subsets of  $R^d$ , this is a very general notion, but since we are only dealing with subset of  $R^d$  for the moment so I have taken them to be subsets of  $R^d$ . Then we define the  $\limsup$  the limit superior as  $n$  goes to infinity of  $A_n$  this is by definition the intersection  $n = 1$  to infinity of the union  $m$  greater than equal to  $n$ .

So,  $m$  from  $n$  to infinity  $A_m$  and similarly, the limit inferior  $\liminf$  of  $A_n$  as  $n$  goes to infinity, this is the union  $n = 1$  to infinity and then we take the intersection of  $m = n$  to infinity  $A_m$ . So, to gain an idea of what these  $\limsup$  and  $\liminf$  describe, the following lemma is quite useful it says that the  $\liminf$  of  $A_n$  as  $n$  goes to infinity, this set can be described as the set of all  $x$  in  $R^d$  such that  $x$  belongs to all but finitely many  $A_n$ 's.

So, all but finitely many meaning that there may be finitely many  $A_n$ 's say  $n_1, n_2$  and  $n_k$  for which  $x$  does not belong to those sets, but it belongs to all the other sets. Similarly, the  $\limsup$  of  $A_n$  as  $n$  goes to infinity this is the set of all points says that  $x$  belongs to infinitely many  $A_n$ 's. So, the difference between the 2 is that  $x$  for the second one  $x$  may not belong to all but finitely many.

(Refer Slide Time: 22:29)

Lemma:

$$\liminf_{n \rightarrow \infty} A_n = \left\{ x \in \mathbb{R}^d \mid x \text{ belongs to all but finitely many } A_n \right\}$$

$$\limsup_{n \rightarrow \infty} A_n = \left\{ x \in \mathbb{R}^d \mid x \text{ belongs to infinitely many } A_n \right\}$$

---

e.g. for  $x \in \limsup_{n \rightarrow \infty} A_n$ , we may have that

$$x \in A_n \quad \forall n \text{ even} \quad x \notin A_n \quad \forall n \text{ odd}$$

Corollary: In any case we have that

$$\liminf_{n \rightarrow \infty} A_n \subseteq \limsup_{n \rightarrow \infty} A_n$$

For example, eg for  $x$  in  $\limsup$  of  $A_n$  we may have that  $x$  belongs to  $A_n$  for all  $n$  even, and  $x$  does not belong to  $A_n$  for all  $n$  odd. So, in this case, there are infinitely many sets  $A_n$  such that  $x$  does not belong to those sets. So, this  $x$  does not belong to the  $\liminf$  but it belongs to the  $\limsup$ , but in any case, we have that  $\liminf$  of  $A_n$  is a subset of  $\limsup$  of  $n$ . So, this is a corollary of the lemma that because, this set is defined.

If we take this definition as the set of all  $x$  which belongs to all but finitely many and the right hand side is belongs to infinitely many. So, of course, if  $x$  belongs to all but finitely many  $A_n$ 's, then it belongs to infinitely many  $A_n$ 's, but the vice versa is the converse is not true as we see in this example. So, in this way, we have a more tangible definition or more practical definition of what  $\limsup$  and  $\liminf$  actually describe. Now, we will use these 2 sets to prove our implication from 5 to 1.
