Properties of the Lebesgue Measure: Inner Regularity, Upward and Downward Monotone Convergence Theorem, and Dominated Convergence Theorem for Sets-Part 1

(Refer Slide Time: 00:14)

Measure Theory - Lecture 17

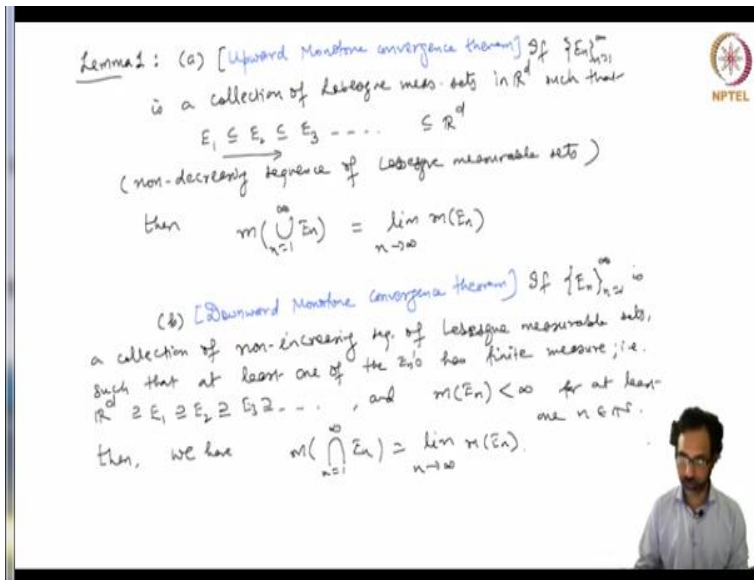

Further Properties of the Lebesgue measure:

1. Upward and Downward monotone convergence theorems
2. Dominated convergence theorem
3. Inner regularity with respect to compact sets

RR: All the above properties are essentially consequences of the countable additivity of the Lebesgue measure.

So, we continue our study of the Lebesgue measure and in this lecture we will look at three main properties of the Lebesgue measurable sets. The first one is called upward and downward monotone convergence theorems and the second one is the dominated convergence theorem and the third one is called inner regularity with respect to compact sets. So, all of these, so let me put this as a remark that all these properties all the above properties are essentially consequences of the countable additivity property of the Lebesgue measure, so let me state these properties as lemmas.

(Refer Slide Time: 01:26)

So, the first one, so let me call it lemma 1 a, this is the upward monotone convergence theorem and this states that if E_n , n equal to 1 to infinity is a collection of Lebesgue measurable sets in \mathbb{R}^d such that we have a nested sequence of non decreasing sets E_1 is a subset of E_2 is a subset of E_3 and so on, then all of these are subset of \mathbb{R}^d . So, this is a non decreasing sequence of Lebesgue measurable sets then the measure of the union n equal to 1 to infinity E_n which is again Lebesgue measurable.

So, the measure of the countable union of all these E_n 's is equal to the limit as n goes to infinity of the sequence of measures $m(E_n)$. So, this is the upward monotone convergence theorem, this is upward monotone means that you are going higher and higher in the nested sequence of sets. And monotonicity property of the Lebesgue measure gives the name monotone convergence theorem, so this is the upward monotone convergence theorem.

The second one is the downward monotone convergence theorem, so this states that if again E_n is a collection of non increasing. So, this is the reverse way sequence of Lebesgue measurable sets such that at least one of the E_n 's has finite measure. So, in symbols we have E_1 is a superset of E_2 is a superset of E_3 and so on. And all of these are subsets of \mathbb{R}^d and $m(E_n)$ is finite for at least one n in the natural numbers.

So, then we have that the measure of the intersection now of all these E_n 's, n equal to 1 to infinity is equal to the limit n tends to infinity of the sequence $m E_n$. So, notice that, in the first in the part A there is no assumption for finiteness of measure of any of the E_n 's. But in the second one, we do need that $m E_n$ is finite for at least one of the E_n 's, so let us see the proof of this lemma.

(Refer Slide Time: 05:44)

$$E := \bigcup_{n=1}^{\infty} E_n = \bigcup_{n=1}^{\infty} \left(E_n \setminus \bigcup_{k=1}^{n-1} E_k \right)$$
 Lacunae (for the sets E_n)

if $E'_n = E_n \setminus \bigcup_{k=1}^{n-1} E_k$

then $E'_n \cap E'_m = \emptyset$ if and only if $n = m$.

and each E'_n is Lebesgue measurable.

$\therefore m(E) = \sum_{n=1}^{\infty} m(E'_n)$ (since $E = \bigcup_{n=1}^{\infty} E'_n$ & countable additivity)

in our case we have $E_1 \supseteq E_2 \supseteq E_3 \supseteq \dots$
 So $\bigcup_{k=1}^{n-1} E_k = E_{n-1} \Rightarrow E_n \setminus \bigcup_{k=1}^{n-1} E_k = E_n \setminus E_{n-1}$

So, for part a we have that the union of all these this can be written as, so let me denote this by E . And this can be written as a disjoint union of sets n equal to 1 to infinity, $E_n - \text{union } k \text{ equal to } 1 \text{ to } n - 1 E_k$. So, these are called Lacunae for the sets E_n and this makes each of this Lacunae disjoint from any other Lacunae. So, this also gives you an increasing family of sets. So, let me write if E_n prime is equal to this $E_n - \text{this Lacunae } k \text{ equal to } 1 \text{ to } n - 1 E_k$.

Then E_n prime m intersection E_n prime m is equal to the empty set is an only if n equal to m . So, this is the collection of E_n primes is pair wise disjoint say disjoint collection of sets and each of these each E_n prime is Lebesgue measurable. Because the finite union of the E_k 's is measurable and the complement is measurable and then again there is an intersection with a Lebesgue measurable set E_n this is also measurable.

So, for each E_n prime is Lebesgue measurable. So, therefore we have the measure of E is equal to the sum n equal to 1 to infinity $m E_n$ prime. Because since E is a disjoint union of all these

Lebesgue measurable sets. We have from countable additivity property we have that the measure of E is just the sum. So, this is for any collection of countable collection of Lebesgue measurable sets E_n . But in our case, we have a non decreasing sequence E_1 is a subset of E_2 is a subset of E_3 and so on. So, the union of k equal to 1 to $n - 1$ E_k is nothing but $E_{n - 1}$. So, in our case this Lacunae $E_n - E_{n - 1}$ equal to 1 to $n - 1$ E_k this is nothing but $E_n - E_{n - 1}$. So, once we have this formula we can rewrite it.

(Refer Slide Time: 09:39)

Handwritten mathematical derivation on a whiteboard:

$$m\left(\bigcup_{n=1}^{\infty} E_n\right) = \sum_{n=1}^{\infty} m(E_n \setminus E_{n-1})$$

$$= \lim_{n \rightarrow \infty} \sum_{k=1}^n m(E_k \setminus E_{k-1})$$

(here we let $E_0 = \phi$)

Now $\sum_{k=1}^n m(E_k \setminus E_{k-1}) = m\left(\bigcup_{k=1}^n (E_k \setminus E_{k-1})\right) \stackrel{\text{[check this with set arithmetic]}}{=} m(E_n)$

But since $E_{k-1} \subset E_k \Rightarrow \bigcup_{k=1}^n (E_k \setminus E_{k-1}) = E_n$

$$\Rightarrow m\left(\bigcup_{n=1}^{\infty} E_n\right) = \lim_{n \rightarrow \infty} m(E_n)$$

The whiteboard also features a Venn diagram showing nested rectangles E_1, E_2, E_3 and a diagram of a set E_n partitioned into disjoint regions $E_1 \setminus E_0, E_2 \setminus E_1, \dots, E_n \setminus E_{n-1}$. An NPTEL logo is visible in the top right corner.

So, now the for our case the union of all these E_n 's when you have a non decreasing sequence this is equal to the sum of the measures $m E_n - E_{n - 1}$, n equal to 1 to infinity. And this is by definition the limit of all these partial sums 1 to k equal to 1 to n $m E_k - E_{k - 1}$ this is by definition of the infinite sum. Here we let E_0 to be the empty set because if k equal to 1 we will get E_0 but our sequence of sets starts from E_1 .

But we can without loss of generality right E_0 to be the empty set and so now this limit formula makes sense. So, now we look at these partial sums k equal to 1 to n $m E_k - E_{k - 1}$ because each of these for each k this is a collection of disjoint sets the Lacunae are disjoint. So, this is nothing but the union k equal to 1 to n $E_k - E_{k - 1}$ but since $E_{k - 1}$ is a subset of E_k . This implies that the union k equal to 1 to n $E_k - E_{k - 1}$ is nothing but E_n , because, so this is something like this as a Venn diagram, you have E_1 , then you have E_2 , then you have E_3 and so on 3.

And so for example here if you take union k equal to 1, 2, 3 $E_k - E_{k-1}$. So, the first part is nothing but for k equal to 1 this is nothing but whole of E_1 then you will get this part in red $E_2 - E_1$ and then you will get $E_3 - E_1$. So, in total you will get nothing but the last term of the series which is nothing but E_3 . And similarly you can check this with set that set arithmetic again that indeed the union of these Lacunae will give you E_n .

So, therefore on the right hand side we get $m E_n$ and so we get our required result that thus union has measured given by the limit of $m E_n$. Notice that we did not assume any finiteness of the measures because we are not cancelling anything from both sides of the equation. So, we can all the arguments that we give works whether each of these measures are finite or infinite.

(Refer Slide Time: 13:56)

(b) $A^d \supseteq E_1 \supseteq E_2 \supseteq E_3 \supseteq \dots$
 s.t. at least one of the E_n 's has finite measure.
 WLOG we may assume that $m(E_1) < \infty$
 Now, let $G_k = E_k \setminus E_{k+1}$ this is a Lebesgue measurable set,
 and $G_k \cap G_{k'} = \emptyset \iff k \neq k'$. [Check].
Claim: $E_1 = \left(\bigcup_{k=1}^{\infty} G_k \right) \cup \left(\bigcap_{k=1}^{\infty} E_k \right) = E \cup \left(\bigcup_{k=1}^{\infty} G_k \right)$
 (Note that E and $\bigcup_{k=1}^{\infty} G_k$ are disjoint.)
 Assuming that the claim is true:

$$m(E_1) = m(E) + \sum_{k=1}^{\infty} m(G_k)$$

$$= m(E) + \lim_{n \rightarrow \infty} \sum_{k=1}^n m(G_k)$$

Now let us see part b, here we have a non increasing sequence of nested Lebesgue measurable sets E_3 and so on and such that at least one of the E_n 's has finite measure. So, know that without loss of generality, we may assume that the measure of E_1 itself is finite, otherwise there can be renumbering of the sequence and the limit remains unchanged. So, we can assume that the first one E_1 has finite measure.

So, now let again G_k be the set $E_k - E_{k+1}$ here because it is a decreasing or other non increasing family of sets. So, earlier we took $E_k - E_{k-1}$ but here we have to take $k + 1$. So, this is a Lebesgue measurable set and again this family of G_k 's is pair wise disjoint meaning that G

G_k and $G_{k'}$ have empty intersection if and only if k is not equal to k' . So, you can check this using again set arithmetic that indeed this is the case, so now I make a claim. So, let me write it as a claim I claim that E_1 can be written as the union k equal to 1 to infinity G_k union with the intersection of n equal to 1 to infinity E_n .

So, let me write this as E , so this is E union k equal to 1 to infinity G_k . So, now note that E and this union k equal to 1 to infinity G_k are also disjoint ok. So, E_1 can be written as a disjoint union of a countable disjoint union of sets E and G_k 's. And so if we assume that the claim is true then we have that the measure of E_1 is equal to measure of E plus the sum k equal to 1 to infinity measure of G_k and G_k was the set $E_k - E_{k+1}$.

So, if you write this as measure of E plus the limit as k tends to infinity or rather n tends to infinity k equal to 1 to n measure of G_k . So, this is by definition of the infinite sum again, so now we are going to see what these partial sums exactly are, so let us see.

(Refer Slide Time: 18:26)

The whiteboard contains the following handwritten text and equations:

$$\sum_{k=1}^n m(G_k) = m(E_1 \setminus E_2) + m(E_2 \setminus E_3) + \dots + m(E_n \setminus E_{n+1}).$$

$$= (m(E_1) - m(E_2)) + (m(E_2) - m(E_3)) + \dots + m(E_n) - m(E_{n+1}).$$

Remark: this above equality holds since $m(E_k) < \infty \forall k \geq 1$.

$$= m(E_1) - m(E_{n+1})$$

$$\Rightarrow m(E_1) = m(E) + m(E_1) - \lim_{n \rightarrow \infty} m(E_{n+1}).$$

Since $m(E_1) < \infty \Rightarrow m(E) = \lim_{n \rightarrow \infty} m(E_{n+1}) = \lim_{n \rightarrow \infty} m(E_n).$

So, this sum k equal to 1 to n measure of G_k this is nothing but the first term is $m(G_1)$ which is $m(E_1 - E_2) + m(E_2 - E_3)$ and so on, so the last term is $m(E_n - E_{n+1})$. So, because all of these are finite, we can write this as $m(E_1) - m(E_2) + m(E_2) - m(E_3)$ and so on and the last term is $m(E_n) - m(E_{n+1})$. So, I will put this as the remark that this above equality holds since $m(E_k)$ is finite for all k greater than equal to 1, so now notice that we have many cancellations.

So, here we have $m E_2 - E_2$ and $+ m E_2$ cancel out, similarly $- m E_3$ will cancel out with the next term which will contain $+ m E_3$ and so on. And $m E_n$ will also cancel out with the last term because the $n - 1$ term is $m E_{n-1} - m E_n$. So, this term and this term will cancel out but we will be left with $m E_{n+1}$ and $m E_1$, so this is nothing but $m E_1 - m E_{n+1}$. So, therefore we have that measure of E_1 is equal to measure of E + measure of E_1 - measure of the limit n goes to infinity $m E_{n+1}$.

So, since again $m E_1$ is finite this implies that we can cancel out $m E_1$ on both sides and so $m E$ is equal to the limit n goes to infinity $m E_{n+1}$ which is the same as the limit n goes to infinity $m E_n$, so we have done except that we have to prove the claim.

(Refer Slide Time: 21:32)

pp the claim: $E_1 = \left(\bigcap_{n=1}^{\infty} E_n\right) \cup \left(\bigcup_{k=1}^{\infty} G_k\right)$

$$\begin{aligned} \left(\bigcap_{n=1}^{\infty} E_n\right) \cup \left(\bigcup_{k=1}^{\infty} (E_k \setminus E_{k+1})\right) &= \left(\bigcap_{n=1}^{\infty} E_n\right) \cup \left(\bigcup_{k=1}^{\infty} (E_k \cap E_{k+1}^c)\right) \\ &= \bigcup_{k=1}^{\infty} \left(\left(\bigcap_{n=1}^{\infty} E_n\right) \cup (E_k \cap E_{k+1}^c) \right) \\ &= \bigcup_{k=1}^{\infty} \left(\underbrace{(E_k \cup \bigcap_{n=1}^{\infty} E_n)}_{E_k \supseteq \bigcap_{n=1}^{\infty} E_n} \cap \underbrace{(E_{k+1}^c \cup \bigcap_{n=1}^{\infty} E_n)}_{\bigcap_{n=1}^{\infty} E_n} \right) \\ &= \bigcup_{k=1}^{\infty} (E_k \cap (E_{k+1}^c \cup \bigcap_{n=1}^{\infty} E_n)) \end{aligned}$$

So, now, let us proof for the claim which stated that E_1 is the union of the intersection of all E_n 's and the union with the union of all the G_k 's k equal to 1 to infinity G_k . So, this is nothing but so let me take this right hand side n equal to 1 to infinity union with the k equal to 1 to infinity and G_k is $E_k - E_{k+1}$. And so this is equal to the intersection n equal to 1 to infinity E_n union with a union k equal to 1 to infinity E_k intersection E_{k+1} complement.

And now we can distribute this set and take this inside the big union. So, this is k equal to 1 to infinity intersection n equal to 1 to infinity E_n . And then you have a union with E_k intersection

E_{k+1} complement and then again we can distribute this inside the intersection. So, you will get E_k union of the intersection n equal to 1 to infinity E_n . And then there is an intersection with the E_{k+1} complement union with the intersection n equal to 1 to infinity E_n .

Now notice that the first one is just E_k because this intersection is contained inside E_k for all k . And so we have k equal to 1 to infinity E_k intersection with this second term which is E_{k+1} complement union with the intersection of all E_n 's. Now we can again distribute this E_k inside, so we will get.

(Refer Slide Time: 24:18)

NPTEL

$$= \bigcup_{k=1}^{\infty} \left(\underbrace{(E_k \setminus E_{k+1})}_{\cap E_k} \cup \underbrace{(E_k \cap \bigcap_{n=1}^{\infty} E_n)}_{E_k} \right)$$

$$= \bigcup_{k=1}^{\infty} E_k = E_1 \quad (\text{since } E_k \subseteq E_1 \forall k \geq 2)$$

RK: We cannot remove the assumption that at least one $m(E_n) < \infty$.

$E_n = [n, \infty) \Rightarrow m(E_n) = \infty \quad \forall n \geq 1$

$\bigcap_{n=1}^{\infty} E_n = \emptyset \Rightarrow m\left(\bigcap_{n=1}^{\infty} E_n\right) = 0 \neq \lim_{n \rightarrow \infty} m(E_n)$

So, here we have k equal to 1 to infinity E_k intersection E_{k+1} complement which is nothing but $E_k - E_{k+1}$. And then you have a union with E_k and then the intersection with the all the intersection of all E_n 's. But this is again E_k and this is a subset of E_k , so the union is again E_k . So, therefore you get k equal to 1 to infinity E_k but since it is a non increasing sequence, this is nothing but E_1 .

Since E_k is a subset of E_1 for all k greater than or equal to 2. So, therefore we have proved our claim and so this proves the downward monotone convergence theorem. One remark about the downward monotone convergence theorem is that we cannot remove the assumption that at least one $m E_n$ is finite. So, as this example shows, so you can take E_n to be the set $n 2 + \infty$, so it is an unbounded set.

So, it is a Lebesgue measurable set and it has measure $+\infty$, in fact this is an elementary set. So, the measure is $+\infty$ for all n greater than or equal to 1, so the intersection of all the E_n 's is empty, so the measure of the intersection is 0. So, this is not equal to the limit of the measures $m E_n$. So, as this example shows that we cannot remove the assumption that at least one of them has finite measure.
