**Basic Properties of L 1-Functions and Lebesgue's Dominated Convergence Theorem**

(Refer Slide Time: 00:13)

$\int_X f d\mu = 0 \Leftrightarrow f = 0 \mu\text{-a.e.} \Rightarrow \|f\|_1 = 0$ .  
 $f = 0 \Leftrightarrow |f| = 0$ .  
 So it suffices to show this for unsigned measurable fn.  
 We suppose that  $f$  is simple:  $f = \sum_{i=1}^n \alpha_i \chi_{E_i}$  where  $E_i$  measurable sets.  
 $f = 0 \mu\text{-a.e.} \Rightarrow$  for each  $i$ , either  $\alpha_i = 0$   
 or  $\mu(E_i) = 0$ .  
 $\Rightarrow \int_X f d\mu = \sum_{i=1}^n \alpha_i \mu(E_i) = 0$ .  
 Now if  $0 \leq g \leq f$ ;  $f = 0 \mu\text{-a.e.} \Rightarrow g = 0 \mu\text{-a.e.}$   
 $\Rightarrow \int_X g d\mu = 0 \Rightarrow$  sub  $\int_X g d\mu = 0 = \int_X g d\mu$ .

So, let us prove the first part and let us prove the reverse implication first which is that  $f = 0$   $\mu$  almost everywhere implies that the L 1 norm is equal to 0. So, first note that  $f = 0$  is equivalent to saying that  $\text{mod } f = 0$  for a any point  $x$ . So, let me take  $x$  here. So, then it is enough to show this property for unsigned measurable functions. So, it suffices to show this for unsigned measurable functions because once you show it, show it for unsigned measurable functions.

You can do it for real valued functions and then for complex valued functions as well. So, let us show this first for unsigned measurable functions. So, if  $f = 0$  for  $\mu$  almost everywhere and so, first we suppose that  $f$  is simple. So, we can do this easy case first. So, let me write  $f$  as a finite linear combination of indicate indicator functions for measurable sets  $E_i$ . So, these are measurable sets.

So, then  $f = 0$   $\mu$  almost everywhere implies that for each  $i$ , either  $\alpha_i$ ; the value of  $f$  is equal to 0 or the measure of  $E_i$  is equal to 0. So, this implies that the simple integral of  $f$  which is the

same as the limit integral of  $f$ . This is equal to the sum  $\sum \mu E_i$  and this is going to be 0. So, it holds for the case when  $f$  is simple. Now, if you take any positive simple function which is bounded above point wise by  $f$ .

Then  $f = 0$   $\mu$  almost everywhere implies that  $s = 0$   $\mu$  almost everywhere which means that the simple integral of  $s d\mu$ . This is 0 by what we have just shown. And so, the supremum of all such simple functions is going to be 0 and this is nothing but the integral of  $f$ . So, we have shown that first unsigned measurable functions when  $f$  is 0 almost everywhere then the  $L^1$  norm is going to be 0.

**(Refer Slide Time: 03:52)**

Ex: Show that for real-valued and then complex-valued abs. integrable fns  $f \in L^1(X, \mu)$

$\Rightarrow$ : To show:  $\|f\|_1 = 0 \Rightarrow f = 0 \mu\text{-a.e.}$

$E_n := \{x \in X : |f(x)| \neq 0\} = \bigcup_{n \geq 1} \underbrace{\{x \in X : |f(x)| \geq \frac{1}{n}\}}_{E_n}$

it suffices to show that  $\mu(E_n) = 0 \forall n \geq 1$ .

$\mu \{x \in X : |f(x)| \geq \frac{1}{n}\} \leq n \cdot \underbrace{\|f\|_1}_0 = 0$ .

$\Rightarrow \mu(E_n) = 0 \forall n \geq 1. \Rightarrow \mu(E_\infty) = 0$ .

So, now I leave it as an exercise to show this for as an exercise. Show this for first real valued and then complex valued measurable absolutely integrable functions. This is  $x$ ;  $f$  is in  $L^1 x \mu$  by breaking these real valued functions in positive and negative parts and using the unsigned case and then using for the complex case, breaking it, breaking into real and imaginary parts and then using the real case. So, I leave it as an exercise.

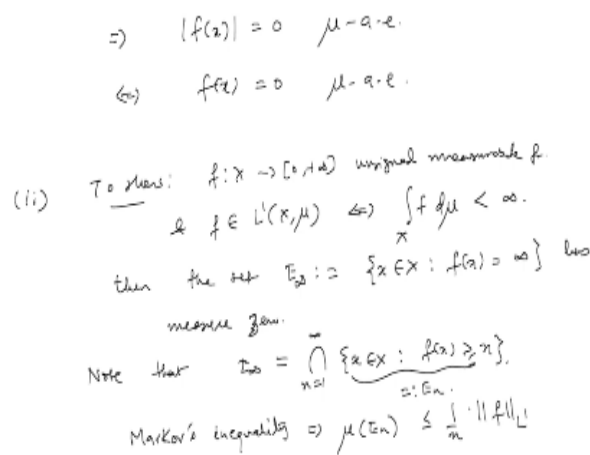

Now, to prove the forward implication which is that if  $f$  has the  $L^1$  norm 0 then  $f = 0$   $\mu$  almost everywhere. So, note that the set. So, the set of points for which  $f x$  not equal to 0. It is a union a countable union of these sets  $f$ . So, let me write again mod  $f$  because if we show that mod  $f x$

equal not equal to 0 has measure 0 then  $f = 0$  also has measure 0. So, mod  $f$  is greater than or equal to  $1/n$ .

And so, if we write these as  $E_n$ , it suffices to show that the measure of  $E_n = 0$  for all  $n$  greater than or equal to  $1$ . So, let us see what are these measures.  $x$  in  $X$  says that mod  $f(x)$  greater than or equal to  $1/n$  and this by the mark of inequality if you take  $\lambda$  to be  $1/n$  then you have  $1/\lambda$  over  $\lambda$ . So,  $n$  times the  $L^1$  norm of  $f$  and this is  $0$ . So, this is  $0$ .

So, this implies that  $\mu(E_n) = 0$  for all  $n$  greater than or equal to  $1$  and this shows that this exceptional set where the modulus is not equal to  $0$ .

**(Refer Slide Time: 06:56)**

$$\Rightarrow |f(x)| = 0 \quad \mu\text{-a.e.}$$

$$\Leftrightarrow f(x) = 0 \quad \mu\text{-a.e.}$$

(ii) To show:  $f: X \rightarrow [0, \infty)$  unsigned measurable  $f$ .

$f \in L^1(X, \mu) \Leftrightarrow \int_X f d\mu < \infty$ .

then the set  $E_\infty := \{x \in X : f(x) = \infty\}$  has measure zero.

Note that  $E_\infty = \bigcap_{n=1}^{\infty} \{x \in X : f(x) \geq n\}$ .

Markov's inequality  $\Rightarrow \mu(E_n) \leq \frac{1}{n} \|f\|_1$

So, let me write this as  $E_n$ . So, this implies that the measure of  $E_n$  is equal to  $0$  which means that this implies that the set of points for which mod  $f(x)$  is equal to  $0$  or rather mod  $f(x) = 0$   $\mu$  almost everywhere and this is equivalent to saying that  $f(x) = 0$   $\mu$  almost everywhere. So, we have shown that if  $L^1$  norm is  $0$  then  $f = 0$   $\mu$  almost everywhere. So, this shows the first part and now let us see what was the second part.

So, if  $f$  is an unsigned measurable function then  $f$  is finite  $\mu$  almost everywhere. So, for the second part we have to show that if  $f$  is an unsigned measurable function and  $f$  belongs to the  $L^1$  absolutely integrable function which is the same as saying that this integral  $d\mu$  is finite. So,

then we have to show that the set  $E_\infty$  which is the set of points such that  $f(x)$  is equal to infinity has measure 0.

So, notice first that this set  $E_\infty$  can be written as an intersection over all positive integers of the sets  $x$  in  $X$  such that  $f(x)$  is greater than or equal to  $n$ . And if these sets are, I denote  $E_n$  then by Markov's inequality implies that the measure of the set  $E_n$  is less than or equal to  $1/n$  times the  $L^1$  norm of  $f$ .

**(Refer Slide Time: 09:23)**

Since  $E_\infty \subseteq E_n \quad \forall n \geq 1$

$$\Rightarrow \mu(E_\infty) \leq \mu(E_n) \leq \frac{1}{n} \|f\|_1 \rightarrow 0 \quad \text{as } n \rightarrow \infty.$$

$$\Rightarrow \mu(E_\infty) = 0.$$

Remark: If  $f$  is finite  $\mu$ -a.e.  $\nRightarrow f \in L^1(X, \mu)$ .

e.g.  $X = \mathbb{R}, \mu = m, f(x) = x$ .

$$\Rightarrow f \notin L^1(\mathbb{R}, m) \text{ even though } f \text{ is finite } m\text{-a.e.}$$

And since  $E_\infty$  is a subset of  $E_n$  for all  $n$  greater than equal to 1. This implies that the measure of  $E_\infty$  is less than or equal to the measure of  $E_n$  and this is less than or equal to  $1/n$  times the  $L^1$  norm of  $f$  and this goes to 0 as  $n$  tends to infinity. So, this means that the measure of  $E_\infty$  is 0. So, we have proved these 2 properties in the corollary. As a remark, I note that if  $f$  is finite  $\mu$  almost everywhere then this does not imply that  $f$  belongs to  $L^1(X, \mu)$  in general.

So, for an example you can take  $X$  to be  $\mathbb{R}$  and  $\mu$  to be the Lebesgue measure on  $\mathbb{R}$  and  $f$  to be the identity function which gives you  $x$ . So, we know that this function is unbounded. And so,  $f$  does not belong to  $L^1(\mathbb{R}, m)$ . Even though  $f$  is finite actually everywhere here but in even if you leave out any null set, we also have  $f$  is finite almost everywhere for the Lebesgue measure. So, the converse for the corollary the second part of the corollary does not hold in general.

(Refer Slide Time: 11:17)

2. [Triangle inequality] If  $f \in L^1(X, \mu)$  then

$$\left| \int_X f d\mu \right| \leq \int_X |f| d\mu =: \|f\|_1$$

pp 6  
=

Proof: First if  $f$  is real-valued:

$$\begin{aligned} \left| \int_X f d\mu \right| &= \left| \int_X f^+ d\mu - \int_X f^- d\mu \right| \\ &\leq \int_X f^+ d\mu + \int_X f^- d\mu \\ &= \int_X (f^+ + f^-) d\mu = \int_X |f| d\mu. \end{aligned}$$

The handwritten proof includes a small diagram of a person in the bottom right corner and an NPTEL logo in the top right corner.

Now, let us look at another important inequality called the triangle inequality and it says that if  $f$  is an  $L^1$  function then the modulus of the integral of  $f$  is less than or equal to integral of the modulus which is nothing but the  $L^1$  norm. So, the  $L^1$  norm bounds the modulus of the complex valued integral of  $f$ . So, let us see a proof. So, first if  $f$  is real valued then the modulus is nothing but the modulus of the positive part minus the negative part and these are 2 complex numbers.

So, this can be written as less than or equal to integral  $f^+ d\mu$  plus the modulus of  $f^- d\mu$  but note that these 2 are already positive. So, you can remove the modulus because they are both positive. And so, this is equal to  $f^+ + f^- d\mu$  and this is nothing but  $|f|$ . So, this is equal to  $|f| d\mu$ . So, if  $f$  is real valued then it is then it follows from the usual triangle inequality for complex numbers. In fact, real numbers here because these are real numbers; positive real numbers.

(Refer Slide Time: 13:36)

if  $f$  is complex valued, we use if  $z \in \mathbb{C}$ , then  
 $z = e^{i\theta} |z|$  for some real  $\theta \in \mathbb{R}$ .

$$\therefore \int_X f d\mu = e^{i\theta} \left| \int_X f d\mu \right| \text{ for some } \theta \in \mathbb{R}.$$

$$\Rightarrow \left| \int_X f d\mu \right| = e^{-i\theta} \int_X f d\mu$$

$$= \int_X (e^{-i\theta} f) d\mu.$$

Taking real part on both sides:

$$\left| \int_X f d\mu \right| = \operatorname{Re} \left( \int_X (e^{-i\theta} f) d\mu \right) = \int_X \underbrace{\operatorname{Re}(e^{-i\theta} f)}_{\leq |f|} d\mu \leq \int_X |f| d\mu.$$

So, we have proved this for the case when  $f$  is real valued. Now; if  $f$  is complex valued, we use that if  $z$  is a complex number then  $z$  can be written as  $e^{i\theta}$  times the modulus of  $z$  for some real number  $\theta$ . So, similarly we can write the integral  $\int f d\mu$  as  $e^{i\theta}$  times the modulus of  $\int f d\mu$  because this belongs to the complex numbers. So, this is for some  $\theta$  in  $\mathbb{R}$ . So, this implies that the modulus of  $\int f d\mu$  is equal to  $e^{-i\theta}$  times  $\int f d\mu$  and by using the linearity property using the for complex scalars.

Now, this is equal to, you can take this complex scalar inside the integral. So, you get  $e^{-i\theta}$  times  $\int f d\mu$  and now you can take the real parts on both sides. So, taking real part on both sides. So, on the left hand side, it is already a real number because you have taken the modulus. So, it does not change. And on the right side, we have the real part of  $e^{-i\theta}$  times  $f$  but the way we have defined complex integrals the real part of the complex integral is the integral of the real part.

So, this is nothing but the real part of  $e^{-i\theta}$  times  $\int f d\mu$  and now this is less than or equal to  $\int |f| d\mu$ . So, this is less than or equal to modulus of  $\int f d\mu$ . So, we have shown that this also holds for complex valued  $L^1$  functions.

**(Refer Slide Time: 16:04)**

Thm. [Dominated convergence thm. for  $L^1$ -fns] :

Let  $\{f_n\}_{n=1}^\infty$  be a seq. of  $L^1$ -fns (absolutely integrable fns).

such that

(a)  $f_n \rightarrow f$   $\mu$ -a.e.

(b)  $\exists$  an unsigned measurable fn.  $g \in L^1(X, \mu)$   
 st  $|f_n| \leq g$   $\mu$ -a.e. ← Dominating  $L^1$ -fn.

Then,  $f \in L^1$  and

$$\int_X \left( \lim_{n \rightarrow \infty} f_n \right) d\mu = \int_X f d\mu = \lim_{n \rightarrow \infty} \int_X f_n d\mu.$$

So, now we come to a very important theorem called the dominated convergence theorem for  $L^1$  functions or absolutely integrable functions. So, we have seen that we can use the monotone convergence theorem for unsigned measurable functions to interchange the limit and integral and the dominated convergence theorem gives you a sufficient criteria when you can interchange the limit and integral for complex valued  $L^1$  functions.

So, let us see the statement of the theorem. So, let  $f_n$   $n = 1$  to infinity be a sequence of  $L^1$  functions. So, here I am abbreviating absolutely integrable functions as  $L^1$  functions absolutely integrable functions. This is  $L^1$  functions in short. So, if you take a sequence of  $L^1$  functions such that first condition is that  $f_n$  converges to  $f$ , a function  $f$ ,  $\mu$  almost everywhere.

And secondly that there exists an unsigned measurable function  $g$  which is also absolutely integrable or integrable such that the all these  $f_n$ 's the modulus of all these  $f_n$ 's is bounded above by  $g$  again  $\mu$  almost everywhere. So, then the statement of the theorem says that then we can interchange the limit and the integral sign which means that the integral. So, first that  $f$  is in  $L^1$  and the integral of the complex integral of  $f$  is equal to the limit as  $n$  tends to infinity of the integrals of  $f_n$ .

And here again this is a interchange of limit and integration because on the left hand side you have the limit inside and here you have the limit outside the integral on the right hand side. So,

this is called the dominated convergence theorem because we have a dominating function  $g$  dominating  $L^1$  function  $g$  which bounds all these  $f_n$ 's and this guarantees that your limit is going to be  $L^1$  and you can write the limit the integral of the limit is as the limit of the integrals.

So, here we use the technical condition that our measure space is complete. So, let me just write it here. So, we let  $(X, \mathcal{B}, \mu)$  be a complete measure space. So, this holds for complete measure space because we have seen that for complete measure spaces a sequence of measurable functions converging almost everywhere to another function gives you a measurable function.

**(Refer Slide Time: 19:58)**

pp: Note that  $f$  is measurable (since it is a limit a.e. of measurable  $f_n$ ). We also have that

$$|f| = \lim_{n \rightarrow \infty} |f_n| \leq g \in L^1.$$

$\Rightarrow f \in L^1(X, \mu)?$

To show:  $\int_X f d\mu = \lim_{n \rightarrow \infty} \int_X f_n d\mu$

It suffices to show this for real-valued  $f_n, f$ .

$$|f_n| \leq g \Rightarrow -g \leq f_n \leq g$$

$$\Rightarrow g + f_n \geq 0 \quad \text{and} \quad g - f_n \geq 0.$$

So, we need this completeness business but once we have that it is not very difficult to establish the proof. So, first note that  $f$  is measurable since it is a limit of measurable functions. It is a limit almost everywhere of measurable functions  $f_n$ . Secondly, we also have the modulus of  $f$  is equal to the limit as  $n$  goes to infinity of the modulus of  $f_n$  and this is bounded above by this function  $g$  and this is an  $L^1$  function.

So,  $f$  is in fact an  $L^1$  function. So, now we are only left to show that the integral of  $f d\mu$  is the limit of the integrals of  $f_n d\mu$ . So, first note that it suffices to show this for real valued functions only by taking comp real and imaginary parts for complex valued functions. So, it suffices to show this for real valued functions  $f_n$  and  $f$ . So, we assume that all the  $f_n$ 's are real valued and all and the limit  $f$  is of course again real valued.

So, then we have that modulus of  $f_n$  is less than or equal to  $g$ . This is given this implies that  $-g$  less than or equal to  $f_n$  is less than or equal to  $g$ . So,  $f_n$  lies between  $-g$  and  $g$ . And this implies that first that  $g + f_n$  is positive and  $g - f_n$  is also a positive function.

**(Refer Slide Time: 22:23)**

Applying Fatou's lemma: so  $g + f_n \geq 0$  &  $g - f_n \geq 0$ .

$$\int_X \liminf_{n \rightarrow \infty} (g + f_n) d\mu \leq \liminf_{n \rightarrow \infty} \int_X (g + f_n) d\mu$$

$g + f = \limsup_{n \rightarrow \infty} f_n$

$$\Rightarrow \int_X g d\mu + \int_X f d\mu \leq \liminf_{n \rightarrow \infty} \left( \int_X g d\mu + \int_X f_n d\mu \right)$$

since  $\int_X g d\mu < \infty$

$$\Rightarrow \int_X f d\mu \leq \liminf_{n \rightarrow \infty} \int_X f_n d\mu$$

So, now we are going to apply Fatou's lemma, applying Fatou's lemma. So, remember that Fatou's lemma was only applicable for unsigned measurable functions. So, we are going to apply it for both these functions  $g + f_n$  and  $g - f_n$ . So, first if we take  $g + f_n$ , we will get integral  $\liminf$  of  $g + f_n d\mu$  as  $n$  goes to infinity is less than or equal to  $\liminf$  as  $n$  goes to infinity integral of  $g + f_n d\mu$ .

Now, this is nothing but  $g + f$  because this is the  $\liminf$  and  $\limsup$  of  $f_n$  both. So, in particular it is equal to the  $\limsup$ ;  $f$  is equal to the  $\limsup$ . So, the  $\liminf$  of  $g + f_n$  is equal to  $g + f$ . So, this implies that integral  $g d\mu +$  integral  $f d\mu$  by using linearity. I am writing it as 2 integrals  $g d\mu + f d\mu$ . And this is less than or equal to the  $\liminf$  as  $n$  goes to infinity integral  $g d\mu +$  integral  $f_n d\mu$  but this first one does not have any dependence on  $n$ .

So, you can take this  $\liminf$  inside. So, this is equal to integral  $g d\mu + \liminf$  as  $n$  goes to infinity integral  $f_n d\mu$  and now we can cancel these two  $g d\mu$ 's integral because these are finite. So,

since integral  $g \, d\mu$  is finite, this implies that integral of  $f \, d\mu$  is less than or equal to  $\liminf_n \int f_n \, d\mu$ .

**(Refer Slide Time: 25:02)**

Similarly, Fatou's lemma for  $g - f_n \geq 0$ .

$$\int_X \liminf_{n \rightarrow \infty} (g - f_n) \, d\mu \leq \liminf_{n \rightarrow \infty} \int_X (g - f_n) \, d\mu,$$

Negate on both sides and we use

$$-\left(\liminf_{n \rightarrow \infty} a_n\right) = \limsup_{n \rightarrow \infty} (-a_n) \text{ for any sequence of the real numbers } \{a_n\}.$$

$$\Rightarrow -\int_X \liminf_{n \rightarrow \infty} (g - f_n) \, d\mu \geq -\liminf_{n \rightarrow \infty} \int_X (g - f_n) \, d\mu.$$

$$\Rightarrow \int_X \limsup_{n \rightarrow \infty} (f_n - g) \, d\mu \geq \limsup_{n \rightarrow \infty} \int_X (f_n - g) \, d\mu.$$

$$\Rightarrow \int_X f \, d\mu - \int_X g \, d\mu \geq \limsup_{n \rightarrow \infty} \int_X f_n \, d\mu - \int_X g \, d\mu.$$

Similarly, we can use it. We can apply Fatou's lemma for  $g - f_n$  which is again a positive sequence of functions and for this, we again have  $\liminf_n \int g - f_n \, d\mu$  is less than or equal to the  $\liminf$  as  $n$  tends to infinity  $\int g - f_n \, d\mu$ . And now we take the negation on both sides.

So, negate on both sides and we use the fact that  $\liminf_n$  tends to infinity with a negative sign of some sequence  $a_n$  is equal to  $\limsup_n$  tends to infinity of  $-a_n$  for any sequence of real or positive real numbers of positive real numbers  $a_n$ . So, here we will get minus integral of  $\liminf_n$  tends to infinity  $\int g - f_n \, d\mu$  is greater than or equal to minus  $\liminf_n$  tends to infinity  $\int g - f_n \, d\mu$ .

And so, now we can use this fact here of about  $\limsup$  and  $\liminf$  when you take the negation. So, this is nothing but integral  $\limsup_n$  tends to infinity  $\int f_n - g \, d\mu$  and on the right hand side, you will get  $\limsup_n$  tends to infinity  $\int f_n - g \, d\mu$  but on the left hand side, the  $\limsup$  of  $f_n$ 's is simply  $f$ . So, you get  $\int f \, d\mu - \int g \, d\mu$ .

And on the right hand side, you get  $\limsup_{n \rightarrow \infty} \int f_n d\mu$  minus  $\int g d\mu$  but now this function  $g$  is an  $L^1$  function. So, these terms are finite the integrals are finite. So, they cancel out.

(Refer Slide Time: 28:27)

$$\Rightarrow \int f d\mu \geq \limsup_{n \rightarrow \infty} \int f_n d\mu$$

$$\Rightarrow \liminf_{n \rightarrow \infty} \int f_n d\mu \geq \int f d\mu \geq \limsup_{n \rightarrow \infty} \int f_n d\mu$$

Since  $\liminf_{n \rightarrow \infty} \int f_n d\mu \leq \limsup_{n \rightarrow \infty} \int f_n d\mu$

$$\Rightarrow \int f d\mu = \lim_{n \rightarrow \infty} \int f_n d\mu$$

And this implies that  $\int f d\mu$  is greater than or equal to the  $\limsup_{n \rightarrow \infty} \int f_n d\mu$ . So, in total, we get that the  $\liminf_{n \rightarrow \infty} \int f_n d\mu$  is greater than or equal to the  $\int f d\mu$  which is greater than or equal to  $\limsup_{n \rightarrow \infty} \int f_n d\mu$  and because we always have since  $\liminf_{n \rightarrow \infty} \int f_n d\mu \leq \limsup_{n \rightarrow \infty} \int f_n d\mu$  integral is less than or equal to the  $\limsup_{n \rightarrow \infty} \int f_n d\mu$ .

This implies what we need which is that the  $\int f d\mu$  is equal to the  $\limsup_{n \rightarrow \infty} \int f_n d\mu$  or the  $\liminf_{n \rightarrow \infty} \int f_n d\mu$  and the limit when they are all the same, we just write  $\lim_{n \rightarrow \infty} \int f_n d\mu$ . And this is the proof of the dominated convergence theorem.
